THE
EDINBURGH ENCYCLOPÆDIA,

CONDUCTED BY

DAVID BREWSTER, L. L. D. F. R. S.

With the assistance of

GENTLEMEN EMINENT IN SCIENCE AND LITERATURE.

THE

FIRST AMERICAN EDITION,

Corrected and improved by the addition of numerous articles relative to

THE INSTITUTIONS OF THE AMERICAN CONTINENT,

ITS GEOGRAPHY BIOGRAPHY, CIVIL AND NATIONAL HISTORY, AND TO VARIOUS DISCOVERIES IN

SCIENCE AND THE ARTS.

IN EIGHTEEN VOLUMES.

VOL. III.

Philadelphia:

PUBLISHED BY JOSEPH AND EDWARD PARKER.

1832.

William Brown, Printer.

THE AMERICAN EDITION

OF THE NEW

EDINBURGH ENCYCLOPÆDIA.

ASTROPHANOMETER, another name given by Jeaurat to instruments resembling the Astereometers or Astrometers of Jeaurat and Dr Brewster, described under the last of these articles. (9)

ASTRUC, JOHN, M. D. a very eminent French physician, who was born at Sauve, a town of Lower Languedoc, on the 19th of March 1684, and died at Paris the 5th of May 1766, at the advanced age of 82. He completed his education at Montpellier, and in 1702 obtained from that university a bachelor's degree in medicine. Soon afterwards he distinguished himself in a controversy with the mechanical physicians on the subject of digestion, which he considered to be the effect of a peculiar ferment, and not of trituration, as Pitcairn and others had obstinately maintained. He obtained in 1710 the professorship of anatomy and medicine at Thoulouse; and in 1716, he succeeded to the chair become vacant at Montpellier by the death of Chatelain. His reputation for learning and medical skill was here fully established; and in 1729 he was invited to remove to Poland, where he was appointed physician to Augustus II., but he very soon quitted that court, and returned to France. He now fixed himself at Paris, and so early as 1730 he was made consulting physician to the French king, and on the death of Geoffroy he received the appointment of professor of medicine in the Royal College. He became also doctor regent of the faculty of physic at Paris. Astruc merited these honours: he was unquestionably a man of great learning, a distinguished writer, and a very skilful physician; his celebrity as a teacher drew to Paris a crowd of pupils from all parts of Europe, and his work *De Morbis Venercis*, published in 1736, every where established his fame as an author. His *Traité des Maladies des Femmes*, published in 1761, also possesses great merit. His other acknowledged works are: A dissertation *De Motu Fermentativi Causa*, 1702; *De Hydrophobia*, 1720; *Sur l'Origine des Maladies Epidemiques*, 1721; *Memoires pour l'Histoire Naturelle de Languedoc*, 1737; *Tractatus Pathologicus*, 1745; *Tractatus Therapeuticus*, 1748; *Traité des Tumeurs et des Ulceres*, 1759; *Conjectures sur les Memoires Originaux dont il paroit que Moise se*

VOL. III. PART I.

servit pour composer le livre de Genese, 1759; *Art d'Acoucher reduit à ses principes*; and published after his death by Lorry, *Memoires pour servir à l'Histoire de la Faculté de Médecine de Montpellier*. (9)

ASTURIAS. Two provinces on the north of Spain: containing about 700 square leagues of the most mountainous country of the whole monarchy, from what is called the principality of Asturias. According to some writers, these two provinces are to be considered separate and distinct, one being the Asturia of Oviedo, and the other the Asturia of Santillana; but no such division is recognized in the administration of the kingdom. This principality is bounded on the north by the bay of Biscay; by Galicia on the west; and by the kingdoms of Leon and Old Castile on the south and east.

The climate is excessively humid; and no care can preserve grain or fruit from decay, and iron from rust. The atmosphere is continually surcharged with vapour, which is attracted by the mountains, and unless the wind blows from north-east, the sky is covered with clouds.

The whole principality abounds with marl, chalk, gypsum, and very fine marbles. The limestone is full of fossil shells, coral, and corallines. Amber, independent of being found on the shore, exists in a fossil state, uniformly accompanied by jet, and a kind of cannel coal. These, when broken, disclose white crusted nodules, including bright and transparent amber. There is abundance of coal deposited in a calcareous bed, which has never been worked for fuel, both because plenty of wood can easily be procured for that purpose, and because it emits an intolerable odour in burning. There are also strong prejudices entertained against it, as being injurious to health. The ancients, particularly Pliny and Silius Italicus, speak of the gold of the Asturian mountains, but none is known now to be there. Mines of copper, lead, and iron, are found; and likewise those of arsenic and cobalt.

Woods, consisting of elm, ash, and poplar, cover the hills. Many trees fit for domestic purposes, or useful in ship building, particularly oaks of very fine quality, abound; and fruits are produced in sheltered places without care or cultivation.

A

ASTURIAS.

The cattle of the Asturias grow to considerable size : they universally supply the place of horses for agricultural uses. Martial and Silius both speak of the Asturian horses. It does not appear, however, that they are at this day equally celebrated.

The Asturias contain a bishopric, 668 parishes, 23 monasteries and nunneries, and 13 other religious establishments. The total population is about 350,000 persons. Besides dignitaries of the church, the number of religious, including 200 nuns, is 2858, which is less in proportion than in some other parts of Spain. From the nature of the climate, the mode of life pursued, and certain predisposing causes, the people are subject to many severe diseases, such as fevers, dropsy, scrofula, palsy, leprosy, and others. The *mal de rosa* attacks the back of the hands, the insteps, and the neck, where it descends to part of the breast, but leaves the rest of the body free. At first it appears red, attended with pain and heat, and ends in scurf. Vertigo and delirium succeed in the progress of the disease, and another extraordinary symptom, consisting in a peculiar propensity of the patients to drown themselves. The disease disappears in summer, and returns in spring : it may be cured by gentle medicines, but if neglected terminates in scrofula, marasma, melancholy, and insanity. The inhabitants are also grievously afflicted with leprosy, for which there are no less than 20 hospitals in the Asturias. Some labouring under it are covered with a dry white scurf, and look like so many millers : some have the skin almost black, full of wrinkles, and covered with a loathsome crust : some have one leg and thigh swollen to an enormous degree, with many pustules and ulcers ; while in others, especially women, the swelling seizes one hand or the face, and hardly leaves the human features discernible. Certain patients, again, amidst the variety which this disease assumes, have carbuncles as large as hazel nuts all over the surface of the body.

Formerly the lower classes were in a condition but little better than bondage. Now, however, they are not *adscripti glebe*, because a great portion of the peasantry abandon their native soil in quest of employment, and are absent even for whole years. During the interval, the ground which they would have had to labour is cultivated by their wives. An indulgence is shewn to tenantry here, of which we have hitherto found no example in other countries, and which we can scarce reconcile with our notions of the right of property in land. A landlord in the Asturias, as elsewhere, could remove his tenants at the expiry of their leases ; but a royal ordinance interposed in the year 1755, stating, that the principal cause why agriculture declined was, the unlimited power of landlords to eject their tenants at the termination of their leases : and it declared, that thenceforward, if a farmer cultivated his lands properly, and was in no considerable arrear, he should neither be removed, nor have the rent raised. Both landlord and tenant were empowered to appeal to skilful persons, in order that the value of the farm might be ascertained ; or to fix the compensation which a tenant on quitting it should receive for the improvements he had made. The chief estates of the Asturias are said to be in the hands of 80 families, and those of the next degree belonging to the clergy.

The great extent of surface occupied by mountains limits the quantity of agricultural produce ; nevertheless wheat, rye, barley, and maize, are cultivated with success, and another kind of corn called *escanda*, afford-

ing white flour of good quality. Two crops in one year are obtained from the low lands, in which case barley follows either maize or flax. But the operations of the peasantry are rude and unskilful. Their ploughs are ill constructed, being adapted only to scratch the ground, which rather requires a deep furrow ; and their harrows have no iron. These are used only for maize, as the wheat and barley never undergo harrowing. Their cart wheels are made of planks, and are fashioned without spokes ; and the axles, to which no grease is applied, are eight or ten inches in diameter. An immoderate degree of friction, produced by such a clumsy apparatus, is increased by the most injudicious expedients. In some of the ravines of the mountains, horizontal water wheels are seen driving the mills. Very considerable quantities of fruit are gathered throughout the principality, and much cyder is made from the apples. This is maintained to be inferior to English cyder, for two reasons : first, because the inhabitants neither pay sufficient attention to the proper selection of fruit, nor to the treatment of the liquor ; and secondly, because its quality is impaired by the extreme humidity of the climate. There are some vineyards, but no wine is made from their produce. Though the Asturias chiefly consist of successive mountains, there are several extensive pastures, grazed by numerous flocks of sheep and cattle.

The whole commerce of the Asturias is inconsiderable : the imports are, linen, woollen stuffs, and hardware goods ; the exports, fruit, cyder and millstones. There are eighteen sea-ports on the coast, some of them so unimportant as hardly to be known by name. They send out shipping to France and England for articles which the province requires. Formerly their whole trade was engrossed by the Dutch, but is now partitioned among other countries. The difficulty of intercourse with the rest of Spain undoubtedly restricts the commerce of the Asturias ; and the roads in general are represented as frightful. There is only one great road leading from Madrid to Oviedo, which traverses this principality : the rest are bye roads, many of them almost impracticable even by a foot passenger. A road runs along the coast forty leagues, or nearly the whole length of the principality. In its course the traveller has to pass thirty-one rivers, only ten of which have bridges. Five of these are crossed in boats ; the remainder must be forded. The dangers of attempting this road on horseback can be but imperfectly conceived. Sometimes the traveller finds himself on the summit of lofty mountains, then in dark and narrow vales ; next buried in the thickest woods, or journeying along the edge of naked precipices. But, to compensate for his difficulties, the true picture of the country is disclosed to his view, here consisting of hills whose tops are covered with snow, while the greenest pasture is seen below ; and there of rocks, cascades, and natural fountains, or fields in a rich state of cultivation.

There are several edifices of Gothic architecture in the Asturias. Not far from Caugas de Onis is the monastery of St Peter Villanosa, said to occupy the site of a palace belonging to Alphonso I. the son of Favila, prince of Oviedo. Here there is a gothic arcade, exhibiting proofs of great antiquity, which is reputed to have been the entrance to the chapel of the palace. At the gate of the church are sculptured the tragical incidents attending the death of the prince Favila, who while hunting was torn to pieces by a wild boar, in 738. Roman antiquities have been found near Gijon.

In regard to the history of the Asturias, it appears that the Romans made ineffectual attempts to subdue them. Florus describes a great body of Asturians descending from the mountains, and boldly attacking the Roman camp. The engagement was long and bloody, and the victory uncertain. When the Moors struggled for the conquest of Spain, and gained a decisive battle at Xeres de la Frontera, in 711, the Asturians received Pelayo and the other Christians, who escaped the force of their arms. The Moors found an impenetrable barrier in the mountains surrounding this province. Their cavalry, which contributed so much to their success in the low countries, was of little use; and after being exposed to various attacks from the Asturians, they judged it expedient to retreat to a distance from the mountains. Pelayo, protected by their fastnesses, here laid the foundation of the Spanish Monarchy; his posterity waged constant war with the Moors, but it was only after a contest of several successive centuries, that they were able to effect their expulsion. From that æra the Asturians derived those privileges of nobility which they still retain: the inhabitants of Ansená are distinguished from the rest of their countrymen, by the title of *Illustrious Mountaineers*. The two provinces of Asturias were erected into a principality, and the oldest son of the Catholic king, under the late dynasty, has from the year 1388 bore the title of prince of Asturias.

The character of the Asturians seems formed, in a great measure, from local circumstances. Extreme simplicity of dress and manners prevail: the women use no artificial decorations, trusting only to what nature has bestowed. The people are distinguished for honour, probity, and candour; every thing bespeaks their remoteness from the more sociable and civilized districts of the kingdom: they are warmly attached to their country, faithful to their rulers, and passive to the laws. They are zealous, perhaps it may be affirmed superstitious, in matters of religion; and inherit a degree of courage frequently the characteristic of mountaineers. Dishonesty is said to be quite unknown among them. Yet, notwithstanding such qualifications, they are accused of dullness, and the want of vivacity, which we may probably, ascribe to the interrupted intercourse subsisting between those who dwell in wild and uncultivated regions. However, they should probably prize their situation, though the source of so many disadvantages, as it removes them from the impression of those convulsions, to which a province more populous, civilized, and accessible, would be exposed.

The state of the sciences is at the lowest ebb in the Asturias: medicine in particular, as now practised, is less calculated to effect a cure than to endanger life. Hence a modern author, in speaking of the frequency of palsy, observes, "The physician has such a dread of palsy, that he bleeds his patient into a dropsy, or leaves him to languish between life and death, a prey to the most gloomy of all diseases to which humanity is subject." See Bourgoing *Tableau de l'Espagne Moderne*, tom. 2. p. 162. Townsend's *Travels in Spain*, vol. i. ii. Laborde's *View of Spain*, vol. ii. Bleau's *Atlas*, tom. 3. Mariana *Historia de Espana*. (c)

ASTYAGES, the last king of Media. See *Herodotus*, lib. i. cap. 74, 75; *Pausanias*, lib. v. cap. 10; *Justin*, lib. v. cap. 4; and *Univers. Hist.* vol. v. p. 40, 47, note (C); 170, (B), &c. See also MEDIA and PERSIA. (w)

ASTYANAX, the son of Hector and Andromache,

who was saved by his mother from the flames of Troy. His superiority to Hector having been predicted by one of the soothsayers, the Greeks are said to have determined his destruction, and Ulysses to have precipitated him from the Trojan walls. See the *Iliad*, lib. vi. v. 400, lib. xxii. v. 500; the *Æneid*, lib. ii. v. 457. lib. iii. v. 489; and Ovid's *Metamorph.* xiii. v. 415. (o)

ASYLUM, from the Greek *ασυλον*, sanctuary, or place of refuge. See SANCTUARY, where this subject will be discussed at considerable length. (j)

ASYMPTOTE, is a line, which, being indefinitely produced, continually approaches another line also indefinitely produced, so that the two lines never meet, though their distance may be less than any assignable magnitude. See CONIC SECTIONS and CURVES. (o)

ATAHUALPA, one of the kings of Quito. See Robertson's *History of America*, vol. iii. p. 29; and QUITO. (w)

ATALANTIS. See ATLANTIS.

ATE, from *αταω*, the same as the goddess of discord among the Latins. She was regarded as the daughter of Jupiter, and the author of all evil. She raised such commotions in heaven, that Jupiter dragged her away by the hair, and threw her headlong to the earth. See the *Iliad*, lib. xix. v. 125. (j)

ATERGATIS, ATARGATIS, or DERCEO, one of the goddesses of the Syrians, whom they represented like a mermaid, with the head and chest of a woman, but with the rest of the body like a fish. According to some, she was the Babylonian and Assyrian Venus, and, like the Astarte of the Phenicians, had her origin from Semiramis, the foundress of Babylon. See *Strabo*, lib. xvi. p. 748.; *Pliny's Nat. Hist.* lib. v. cap. 23.; *Macrobius' Saturnalia*, lib. i. cap. 23.; *Manilius' Astron.* iv.; and Bryant's *Ancient Mythol.* vol. ii. p. 298. (w)

ATHABASCA, the name of a territory, lake, and river, in North America. The inhabitants of this territory carried their furs to Fort-Churchill, Hudson's Bay, till the year 1782; but, since that time, their trading establishment has been on the north side of the river La Pluie, where the inhabitants of Montreal repair to exchange their commodities. See Mackenzie's *Voyages*, Introd. p. 56, &c. (w)

ATHAMANES, the name of an ancient people who inhabited Athamania, in Epirus. They seem to have existed a century before the Trojan war, and to have preserved their name and customs in the days of Alexander. It is said that there was a fountain in their territories, the waters of which became so sulphureous during the last quarter of the moon, that they burned wood. See *Strabo*, lib. vii.; *Pliny*, lib. ii. cap. 103.; *Pompon. Mela*, lib. ii. cap. 3.; and Ovid's *Metamorph.* xv. v. 311. (j)

ATHAMANTA, a genus of plants of the class Pentandria, and order Digynia. See BOTANY. (w)

ATHAMAS, king of Thebes. See *Apollodorus*, lib. i. cap. 7. and 9.; *Pausan.* lib. ix. cap. 34.; *Hygin.* *Fab.* 1, 2, 5.; and Lempriere's *Classical Dictionary*. (j)

ATHANASIA, a genus of plants of the class Syngenesia, and order Polygamia Æqualis. See BOTANY. (w)

ATHANASIUS, SAINT, flourished in the fourth century, and was the renowned champion of orthodoxy against the Arians. We have no certain accounts of his parentage; and all that we know of his younger years is, that he was a native of Egypt, and probably distinguished by his proficiency in the theological learning. He ac-

accompanied the bishop of Alexandria to the council of Nice in the capacity of secretary; and though then only a deacon, distinguished himself greatly by his zeal and his eloquence against Arius, and his party. He recommended himself so much to his patron and employer, that, in the year 326, he succeeded him in the see of Alexandria, by his special nomination. He immediately devoted his time and his talents to a zealous support of the catholic doctrine of the trinity, against the innovations of Arius; and never had any cause a more intrepid advocate. He was five times driven into exile, or forced to abdicate his episcopal see, by the intrigues of his enemies; but his zeal was never diminished by his misfortunes, and he at last triumphed over all his opponents, dying in quiet possession of his see in the year 373. He was first banished by the Emperor Constantine, on the unfounded accusation of detaining at Alexandria the ships which supplied Constantinople with corn. The place of his exile was Treves, in Gaul, where he remained about eighteen months, when he was honourably restored to his see by an edict of Constantius. A council of Arian bishops, held at Antioch, represented this restoration of Athanasius as an encroachment on synodical authority, and confirmed his former deposition. Upon this he fled to Julius, bishop of Rome, and was patronized by the Emperor Constantius, who threatened to make war on his brother Constantius, if Athanasius was not restored. The eastern emperor complied with this demand; but Athanasius was soon assailed by the violence of his adversaries, and, being again deprived of his episcopal authority, was forced to seek an asylum in the desert of Thebais, where he remained unheard of for the space of six years. He was again restored to his see under Julian, and afterwards banished by the same emperor, to whom he was particularly obnoxious. He was afterwards restored by Jovian, and again banished by Valens; he was finally restored under the latter emperor, and ended his days in tranquillity.

The character of Athanasius is thus drawn by Gibbon, who cannot be supposed partial to his tenets: "Amidst the storms of persecution, he was patient of labour; jealous of fame; careless of safety: and though his mind was tainted by the contagion of fanaticism, Athanasius displayed a superiority of character and abilities, which would have qualified him, much better than the degenerate sons of Constantine, for the government of a great empire. His learning was much less profound and extensive than that of Eusebius of Cæsaria, and his rude eloquence could not be compared with the polished oratory of Gregory, or Basil; but whenever the primate of Egypt was called upon to justify his sentiments, or his conduct, his unpremeditated style, either of speaking or writing, was clear, forcible, and persuasive."

Eusebius Renaudotus, in his history of the *Patriarchs of Alexandria*, has collected all the accounts which oriental writers give of Athanasius; and the celebrated Bernard Montfaucon has published a splendid edition of his works, in three volumes folio. His works consist chiefly of apologies for himself, or invectives against his enemies. The most valuable are, his first book "Against the Gentiles;" "Apologies;" "Letter to those who lead a Monastic Life;" "Letters to Serapion;" "Conference with the Arians," &c. &c. Dupin and Cave have enumerated both the genuine and the spurious works of Athanasius. For an account of what

is commonly called the Athanasian Creed, see **CREED**. See Gibbon's *Hist.* vols. iii. and iv. Lardner's *Works*, vol. iv. (v)

ATHANOR, or **ACANOR**, a species of furnace used by the alchemists in the tedious processes, by means of which they expected to produce the precious from the baser metals. It is derived from *athanatos*, immortal, denoting its property of maintaining a long continued heat without attendance, by means of a magazine of fuel connected with it. This instrument is now superseded by furnaces of a more useful kind. (j)

ATHAPUSCOW, or **SLAVE LAKE**, the name of a large lake in North America, about 120 leagues long, and 20 wide; it is variegated with a number of islands covered with trees, and abounds in various kinds of fish. It is connected by rivers with a great number of smaller lakes to the east and north of it, and with the North Sea by Mackenzie's River. According to some maps, it is separate from Slave Lake, and lies to the south of it. N. Lat. 61°, and between the parallels of 112° and 120° west. (w)

ATHEISM, (from *á* priv. and *Θεός*, *God*.) may be defined to be, the total want of religious principle.

The word is generally employed by modern writers to signify, the absolute denial of an Intelligent First Cause. This has been called *pure atheism*. But we conceive, that those who habitually doubt this fundamental doctrine, or who object to all the proofs which have ever been offered in its support, must be considered as subjecting themselves to the same charge, although they may not have arrived at such a degree of hardness, as formally to avow their unqualified disbelief. Lord Shaftesbury thinks it hard that any man should be pronounced an atheist, whose whole thoughts are not steadily and invariably bent, at all times, and in all circumstances, against every supposition of design in things. For the same reason no man can be called a theist, who is not uniformly and constantly convinced that an omnipotent mind has produced the universe; and, if this language be admitted, we know not what name to assign to those who fluctuate in their opinions concerning the origin of the world. We cannot form a conception of the incongruous combination, which his lordship calls a mixture of theism and atheism,—a co-operation of God and chance.

The appellation Atheist may, we think, be applied, with strict propriety, first, to those who pretend that they are unable to discover any evidences of wise design in the formation of the universe; secondly, to those, who not only withhold their assent, but decidedly maintain, that there are no such evidences; and, thirdly, to those who undertake to account for the origin of things without having recourse to the agency of mind. We would extend the term still farther: To those who have no idea of God at all, if any such persons there be; and also to those whose notions of the creating or superintending mind, are completely incompatible with every definition of Deity which has been given by enlightened reason. He who admits that the world exhibits marks of contrivance, and that inconceivable power must have been exerted in bringing it into existence, but at the same time denies, or refuses to recognise, the *moral attributes* of the Supreme Being, is to be accounted an atheist, inasmuch as he does not believe in a Being possessed of those excellencies, which are as essential to the idea of a Divinity, as eternity, ubiquity, and omnipotence. If there be such an opinion as what has been called perfect **Dæmonism**, the belief in a ma-

ignnant first principle, we hesitate not to rank it among the modifications of atheism.

Though this is not the usual acceptation of the word, it is sanctioned by many great authorities. The ancient Stoics applied the name Atheists equally to those who acknowledged no God, and to those who thought or spoke in terms repugnant to the divine perfection,—*τοῖς τὴν ἐναντίας θεῶν λεγόμενοις*. St Paul, in writing to the Ephesian converts, formerly the votaries of Diana, addresses them as having lately been *ἄθεοι ἐν τῷ κόσμῳ*, atheists in the world, because they had paid their adorations to beings who, in the characters ascribed to them, were devoid of every attribute of divinity,—*τοῖς μὴ φύσει οὖσι θεοῖς*. To the same purpose Dr Clarke expresses his opinion, that all who deny the principal attributes of the divine nature are to be numbered among the atheists. In this particular, the language of Mr Hume coincides with that of these Christian writers. All polytheists and idolaters, he remarks, are to be considered as superstitious atheists, because they acknowledged no being who corresponds with our idea of Deity. The fathers of the Christian church branded all the idolatrous Gentiles with this reproachful term; and they, in their turn, retorted the accusation, as Justin Martyr declares in his Apology,—*ἄθεοι κεκλημέθα*, &c. Both parties proceeded on the supposition, that the objects of worship, to whom their adversaries rendered homage, were unworthy of the name of gods: the former abhorring the heathen deities as vanities and dumb idols; and the latter deriding the proselytes of the new faith for setting up *ξένα δαιμόνια*, strange and unheard of demons, because they spoke of Jesus and Anastasis (the resurrection).

Those who, in their moral conduct, give no evidence of their belief in a superior power, or, in other words, who act as if there were no God, are generally denominated practical atheists. In this sense, Sophocles, Plato, and other ancient writers, apply the term to those impious persons who neglect the institutions of divine worship, and contemn the obligations of morality.

It has often been questioned, whether a speculative or contemplative atheist ever existed; and it is generally admitted that the instances have been rare, in which men have so completely divested themselves of the original feelings of the mind, as to take refuge in absolute atheism. Cicero says, that there never was a man who constantly and absolutely denied a God. If this assertion be well founded, there can be no atheists, according to the definition of Shaftesbury and others. All must be exempt from the charge, in whose minds the opinion is not coeval with the very dawn of intelligence, and all who, at the close of life, may have been led, either by some undefined terror, or by the importunity of others, to acknowledge, that their belief was the same with that of other men. Our opinion is, that, in strict propriety of language, the term atheist must comprehend all who are not theists,—all who do not ascribe the formation and government of the world to an intelligent power. In the whole compass of the Pagan history, we find no unequivocal trace of what can, with any degree of correctness, be named polytheism, or the belief in a plurality of uncreated, self-existent beings, the authors and preservers of the world. The opinion of Zoroaster and the Magi concerning a good and an evil principle, commonly called the system of the Manichæans, is the nearest approach to a scheme of polytheism. But it appears to be universally admitted, that the Pagan dei-

ties were never regarded by their worshippers as the creators or governors of all nature; and indeed Aristotle proves the impossibility of conceiving a number of original self-existent beings. These imaginary divinities were either the animating spirits which impelled the heavenly bodies, or they were the souls of good men and heroes departed, or the invisible tutelary powers which watched over particular regions and individuals, or they were abstract qualities personified, as health, temperance, fame, or last of all, they were merely a diversity of appellations referring to the same object. This last Cudworth calls Polyonymy. The religion of the ancients consisted chiefly (or entirely, as Bryant says,) in *Δαιμονολατρεία*, the worship of deified mortals, as mediators between heaven and earth; and, we may add, the invocation of the *genii*, the *lares*, or *fenates*, who may be considered in the same light. Some of them believed, that these various divinities were all subordinate to One Supreme. This was a modification of theism. A great proportion, however, of the people could not be viewed as theists. Addicted to idolatry, or rather to dæmonolatry, they rendered homage, and addressed their prayers, to beings who had no concern in the creation of the world, and whom they believed to have sprung, like themselves, from the air, or the ocean.

Sentiments like these we find in the most ancient poets of Greece. Thus Homer says, *Ὠκεανὸν τε θεῶν γενέσθιν, καὶ μητέρα Τάρτην*. Hesiod is less distinct; but he ascribes the same origin to gods and men, *Ὡς ἰκοῦσθιν γέννασι θεοὶ θνητοὶ τ' ἀνθρώποι*. The scholiast explains *ἰκοῦσθιν*,—*ἔκ τῶν αὐτῶν γένους*. Aristophanes says, that Love, the offspring of Night and Chaos, generated all the gods, as well as other animals. *πρῶτιστον δ' οὐκ ἦν γένους ἀθανάτων, πρὶν Ἐρῶς συνεμιξῆν ἅπαντα*. Pindar also says, *Ἐν ἀνδρῶν, ἐν θεῶν γένους*. We could quote many other expressions from the poets, which even the ingenuity of Aristotle has failed to reconcile with the principles of theism. Longinus, speaking of the gross ideas of the Deity conveyed by Homer, acknowledges, that they are completely atheistical—*πανταπατικὴν ἀθεῖα*.

We are aware, however, that the same writers appear elsewhere to recognise a sovereign God, as the father of all inferior divinities, and the ruler of nature. But as the expressions of the poets are very unsatisfactory, let us inquire how far the opinions of the philosophers were rational and consistent.

If we recur to the earliest times, we are compelled to acknowledge, that the notions of the wise men, as they were called, were at least as chimerical and false as atheism itself: and in the more enlightened periods, we are mortified to find, that though there were a few who ascribed the formation of worlds to a Supreme Mind, there was not one who honoured him as the original creator of matter itself. The substance of which all things are framed, was supposed, by the theists, to be co-eternal with the prime mover, who bestowed on it form, and life, and activity. In vain do we look for the belief in a Being who gave origin to all dependent existences; and if the creation of matter itself is to be considered as an essential attribute of the divinity, we must admit that it does not seem to have entered into the conceptions of the founders of any of the schools. It is perfectly evident, that Anaxagoras, Plato, and Aristotle, the three greatest luminaries of Athens, held the eternity of matter, and applied the incontrovertible axiom, nothing can proceed from nothing, to prove that to the production of the present system, the pre-existence

of a material cause was not less necessary, than the pre-existence of an omnipotent energy or mind.

For an account of the opinion of other Grecian theologians, we would willingly refer to Cicero's treatise *De Natura Deorum*; but we must caution our readers against relying implicitly on his authority. His enumeration is not complete, and his view of the different systems is not only incorrect, but sometimes contradictory. Neither can we vouch for the accuracy of the laborious Cudworth, who, in his attempt to overthrow the different atheistical hypotheses, was anxious to avail himself of every expression in the writings of the ancients which could be interpreted so as to support his peculiar system. Bayle and lord Bolingbroke have many observations on the subject, but they also had preconceived notions to support.

Till the time of Anaxagoras, the leaders of the Ionic school were atheists in the strictest sense of the word. There is some doubt with regard to Thales, whose language is extremely ambiguous; but the tenets of his immediate followers, Anaximander and Anaximenes, are decidedly hostile to the supposition, that mind was the first principle of things. If there were gods, they were either air itself, or the progeny of air. Diogenes Apolloniates held a similar opinion, which approached very nearly to the system of Spinoza.

We shall only mention the names of Democritus, Leucippus, Diagoras, Protagoras, Epicurus, Theodorus, Strato of Lampsacus, Eumerus, Hippo, and Bion of Borysthenes; all of whom either rejected the belief in God altogether, or insisted that it was unnecessary to have recourse to this supposition in order to account for the formation of things; or at least professed themselves unable to perceive any evidences that a God exists.

At a period equally ancient, Confucius, though he spoke sometimes of the Spirit of Heaven, is generally believed to have propagated an atheistical creed among his followers, insomuch, that from his time the literati of China have been considered as a race of atheists. It is alleged by others, that Foë, before his death, revealed to a few disciples his secret doctrine, that inanity and vacuity were the principles of all things; and this incomprehensible dogma having transpired, is said to have given rise to the infidel notions of the philosophers. Couplet the Jesuit endeavours to vindicate Confucius from the charge, and sir William Jones subscribes to the opinion of that missionary; but we must own, that neither in the writings of Confucius, nor in the religious worship of the people, is there any trace of a belief in a Supreme God, or in any powers much superior to human beings. Sir William Temple is said to have been a follower of Confucius, and to have believed that this world existed in its present form from all eternity.

In modern times, the systems of Spinoza and Hobbes have been the most remarkable. The followers of the former call themselves Pantheists, as they maintain God and the universe to be the same. The most impious among them were Meier, a physician, Lucas, also a physician, count Boulainvilliers, and John Toland.

Among modern atheists we may also mention Barbara, the wife of the emperor Sigismund, a rare instance, says Bayle, of such an error being maintained by a woman. Averroës, Campanella, the Popes Leo X. and

Clement VII., Cæsalpinus, Des Barreaux, and Charron, have also been accused by different writers; but with what degree of justice, we do not pretend to decide. We know well, that the following persons suffered death for their perverted zeal in endeavouring to disseminate atheistical principles. Giordano Bruno, the author of many impious works, was burnt at Rome in 1600.* Vanni was burnt at Toulouse, in 1629, and to the last moment obstinately adhered to the profession of his unbelief. Casimir Leszynski, a Polish knight, was burnt at Warsaw, in 1689, and, after the body was consumed, his ashes were collected and shot from the mouth of a cannon. Cosmo Ruggeri, a Florentine, one of the most audacious infidels of any age, died at Paris in 1615, uttering the most horrible impieties. We might have mentioned also, that among the ancients, Protagoras and Diagoras, followers of Democritus, and Theodorus, one of the Cyrenaic sect, were accounted martyrs for atheism. The first was banished, the second condemned and obliged to flee from his country, and the last underwent the punishment of death.

It has been common to reduce this variety of professed atheists to a few general classes. In the first volume of *Observationes Select. ad Rem. lit. Spectant.* it is said, that there were three degrees of atheism among the ancients. 1. The denial of the existence of God: 2. Denying that the world is the work of the God or Gods who are acknowledged: and, 3. Asserting that God, in creating the world, was moved, not by his own free will, but by the invincible necessity of nature. Under the last head, Aristotle and the Stoics are comprehended.

We may in general terms refer all atheists to two principal divisions, those who accounted for the present system of things on the supposition of chance, and those who ascribed all things to fate. Cudworth subdivides these classes into four; two of whom believed matter to be animated, and the two others inanimate. The first class were the *Hylozoists* or *Stratonici*, (so named from Strato of Lampsacus,) who believed all the particles of matter to have life essentially, though without sense or knowledge. Hobbes is supposed to have borrowed some of his notions from this school. A second scheme, called the *Pseudo-Zenonian*, or *Stoical*, supposes the universe to be disposed and ordered by one regular and methodical, but senseless plastic nature. Seneca, and the younger Pliny, appear to have adopted this opinion. The third form, denominated the *Hylopathian*, or *Anaximandrian*, resolves every thing into *ύλην*, matter, and its *πάθηα*, affections, forms, and qualities. This was the unintelligible language of the Ionic philosophers. The last form, the *Democritic* system of atoms, is by far the most considerable, and the best known, chiefly in consequence of its having been adopted by Epicurus, and illustrated by Lucretius in one of the most beautiful productions of the Roman muse,—the poem *De Rerum Natura*. The Anaximandrian and Democritic atheists derive all things from a fortuitous nature, and assert the eternity of matter, but not of the world. The Stratonical and Stoical atheists suppose some life to be fundamental and original, ingenerable and incorruptible; but they do not admit that it possesses consciousness or perception.

All these sects, it will be observed, undertook to solve the phenomena of nature by means of hypotheses, which

* Huet and others have said, that Des Cartes borrowed many of his sentiments from this man.

excluded the operation of mind; but which, it must at once be perceived, were altogether unsusceptible of proof. Modern atheists have in general been more cautious. They have contented themselves with endeavouring to refute the arguments on which the belief in a Deity is founded; and some of them have thought it prudent, like the ancient Pyrrhonists, to entrench themselves in unlimited scepticism. By the aid of metaphysical subtleties, they have sometimes confounded the ignorant, and perplexed even the rational believer. But we are confident, that the wonderful oeconomy of the material world, the evident adaptation of means to ends, the mutual subserviency of different parts of nature, the symmetry, the harmony, the manifest unity of design, and the numerous beneficial provisions for the accommodation and enjoyment of sentient beings, which every moment burst on our notice, cannot be contemplated by a sound and reflecting mind, without irresistibly impressing a conviction, incomparably more powerful than any of the transient doubts, resulting from objections which insinuate that all our knowledge is delusive.

If the indications of design be so abundant, and if the idea of Deity be so natural and obvious, whence is it, that a multiplicity of systems have been contrived by speculative men, to account for the creation of the world without the aid of intelligent power? and what have been the causes which have led numbers to embrace these unsatisfactory tenets, or at least to reject the belief in a God? Lord Bacon says, in one part of his writings, that the principal causes of atheism are curious controversies, and profane scoffing. In another place he adds to these, the unworthiness of priests, and what he calls learned times, especially when attended with peace and prosperity. He says also, that atheism proceeds from folly and ignorance; because, though in the threshold of philosophy, the mind, dwelling on second causes, may be apt to overlook the first cause, yet, by proceeding farther, and marking the dependence and concatenation of the great series of causes, we are brought to believe that the highest link is fixed to the throne of God. These, and other similar expressions, which occur often in the works of this distinguished man, are singular in one respect: For in his Essays he seems to doubt if there were ever any contemplative atheists, except perhaps Bias, Diagoras, and Lucian; and yet he is not struck with the inconsistency of assigning causes for a phenomenon, the occurrence of which appeared to be so questionable. He maintains another position, which most people will think paradoxical: He insists, that the atomical school of Democritus and Leucippus, "which is most accused of atheism, doth most demonstrate religion;" because (as is no doubt true) it is inconceivable that an army of minute particles should have produced this orderly and beautiful universe, without a divine marshal to allot them their several stations. He defends Epicurus against the charge of atheism and of dissimulation; and yet, amidst all his incredulity with regard to the existence of atheists, he says, that no heretics are more anxious to gain proselytes than they, and that they will even suffer in the cause and not recant. We advert to these inconsistencies, because we have seen the authority of Bacon quoted in favour of the opinion, that there can scarcely be a contemplative atheist; whereas it is evident that his lordship's opinion was very fluctuating; and we may have occasion to show hereafter, that some of his other expressions on

the subject are still more apt to mislead the inattentive reader.

We are convinced that atheism must, in all cases, proceed from one or more of the following causes: 1. Gross ignorance and inattention. We know that some protest against branding those with the name of atheists, who have no idea of God, and have never thought of any thing like religion, as we are assured by Leti and Richier, missionaries from Geneva, was the condition of some islanders whom they visited, (*Calvin. Epist. cccxxxvii.*) But we do not know what other name to apply to them. 2. Observation of the apparent inequalities in the government of the world, and particularly the experience of calamity resulting from successful villainy, is said to have precipitated some into atheism. *Dum rapiunt mala fata bonos* (says Ovid), *solicitor nullos esse future Deos.* The stories concerning Diagoras are well known: The infidelity of a friend, and the fall of his country, are said to have led him to doubt of the superintendence of Providence; and thence he was gradually led to deny the first truths of religion. 3. Extreme depravity of manners, and a perverse determination to admit no considerations into the mind which are unfavourable to profligate and vicious habits, is mentioned by Clarke as a source of the most incurable error; and on this also great stress is laid by Bacon, in his paraphrase on the first verse of the 14th Psalm. 4. The enormous absurdity of the vulgar superstitious disgusted many of the ancient philosophers so much, as to induce them to reject all religion. And there can be little doubt, that superstitious misapprehensions concerning the divine character have driven some into atheism, as preferable to the belief in a being whose attributes inspire horror rather than love. *Ὅπου διέτριψεν Θεὸς ἔστιν ὁ ἄθεος, ὁ δὲ δεισιδικίμων οὐ βουλεύεται,* (*Plut.*) 5. Plato assigns another cause, the affectation of singularity, and a desire of seeming wiser than others. He describes atheism as *ἀμαθεία μαλα χαλεπή δοκοῦσα εἶναι μεγίστη φρονήσις.* Some may think that this cause can account only for the profession of an atheistical creed; but it must be recollected, that the mind may gradually, and almost insensibly, be led to the belief of the most pernicious errors, by repeated attempts to defend them. 6. Dr Clarke (in his *Evidences of Natural and Revealed Religion*) endeavours to prove, that, since the appearance of revelation, every deistical pretence (of which he enumerates four) must of necessity terminate in downright atheism. We have no doubt that scepticism on the one subject has a natural tendency to extend itself to the other; and we agree with Butler, that the chief objections which are brought against the gospel may with equal force be urged against the constitution of nature. 7. The refinements of false science have been a prolific source of errors, and, among others, of atheism. Last of all, we are persuaded, that, in modern times particularly, atheism has proceeded more from the weak and inconclusive arguments which have occasionally been employed to prove the being of God, than from any other cause whatever. The detection of a vulnerable argument is always regarded as a triumph by the atheist; and, therefore, it would be a real service to the cause of religion, if those untenable positions were at once abandoned. We do not wonder at the assertion of Plutarch, that some have been converted from atheism by the sight of apparitions; but surely we must be mortified to find Christian divines, at a later period

than the Reformation, gravely asserting, that the existence of devils, as testified by conjurers and necromancers, is a proof that there is a being superior to these malicious spirits, who, if not controuled by a higher power, would speedily sink the whole human race into the most deplorable misery, (*Lud. Vic. de ver. Fid. Christ. Leigh's Body of Divinity, &c.*) Cudworth has, with singular indiscretion, employed several pages to prove the reality of spirit, from the phenomena of apparitions, witches, demoniacs, magic and divination. Even Dr Barrow has not scrupled to derive one of the proofs of the being of God from supernatural effects, in the list of which he includes the divination of the Greek oracles, presignifications of events by dreams, the power of enchantments implying the co-operation of invisible powers, intercourse with bad spirits, strange detections of murders, conspiracies and treasons, and many other supposed interpositions from above, which the soundest believers of this age will hesitate to admit, and which every infidel will treat with derision, (*Barrow*, vol. ii. serm. 9.) A similar imprudence on the part of archbishop Tillotson, in thinking it necessary to prove the beginning of the world from the books of Moses, considered as a historical testimony, and connecting this argument with that for the belief in God, gave occasion to a letter of lord Bolingbroke, more replete with infidelity than almost any other part of his works.—Nay, what is most extraordinary of all, some pious persons have argued thus: There must be a God, for we have his own testimony in his word; and this, say they, is the strongest possible testimony, (*Atheomastix*, by Fotherby, bishop of Salisbury). We are inclined to think also, that too great weight has been laid on the argument, from *universal consent*. Though no nation has been discovered that professes atheism, we do not see that it is by any means clear, that idolatry is a decisive indication of an original sense of deity, which has been gradually corrupted. It may be true, that idolatry and hero-worship are the traces of more enlightened conceptions; but this opinion cannot be proved, and ought not therefore to be assumed. These superstitions, however, may suggest other important conclusions, which we shall take a future opportunity of stating. Of the five arguments proposed by Aquinas, some Catholic divines have rejected four. Herminier says, that it is a paralogism to attempt to prove that there is a deity by any of the following reasons: That there must be a self-existent being; that there cannot be an infinite succession of causes; that matter cannot begin to move of itself; and that, as different degrees of perfection are observable in different beings, there must be a being infinitely perfect. The only argument which this learned person retains, is that which is derived from the structure and government of the universe. Many orthodox writers have, with the same view, endeavoured to prove that the Cartesian argument is inadmissible. And some scolastics have gone so far as to affirm, that all the arguments furnished by human reason amount only to probability. This is a way of talking we cannot too severely condemn. Much harm has been done by injudiciously depreciating the powers of human reason to such a degree as to shake all the foundations of natural religion, which are so intimately conjoined with the evidences of revelation, that the subversion of the one must inevitably prove fatal to the other.

Our limits do not permit us here to enumerate and

to repel the objections which atheists have urged against the belief in a first cause. We shall content ourselves with remarking, 1. That no atheistical scheme has ever been proposed, which is not attended with insuperable difficulties. 2. That there can be no demonstration against the existence of a first cause. 3. That there are the strongest proofs of the existence of an original cause;—and that every other supposition, either of chance or necessity, involves us in contradictions.—The illustration of these remarks, and the discussion of the different arguments and objections, must be reserved for the articles DEITY, and NATURAL RELIGION.

One or two questions connected with this subject still remain to be considered. It may be asked, What connection does there subsist between atheism and other speculative errors? The forms of atheism are so numerous, that we may conceive it to be combined with almost every possible modification of false judgements. We may also assert, that in every instance it is associated with other erroneous principles; but there are some with which it is not so necessarily connected as is often supposed. For instance, no atheistic scheme can prove the impossibility of existing after death. It may weaken the proofs of the soul's immortality, but it cannot prove the contrary.

It may also be inquired, what influence the disbelief of a Deity is likely to produce on the conduct of a man as a moral agent? It is evident at first sight, that if religion be favorable to virtue, atheism must have an opposite tendency. It is possible, indeed, to have a sense of merit and demerit, and a feeling of self-approbation, and disapprobation, antecedent to a fixed belief in a God. This we think will be granted by all at least who consider the internal constitution of the mind, and particularly the power of conscience, as furnishing a proof of a superintending Providence. Without the belief of a God, however, the sanctions of morality are incomplete, and even the standard of right and wrong is undecided. It must at the same time be recollected, that the mere admission that the world was created by a Supreme power, cannot operate as an incitement to virtue, or as a restraint to the vicious, unless the belief of a Providence be superadded. Nor is it enough that we should consider ourselves responsible to the Sovereign Inspector and judge of human actions. Our conduct will not be beneficially influenced by the consideration of the Divine Omniscience, and of our dependence, unless we entertain worthy apprehensions of the attributes and laws of God. The supposition of a Deity, whose purposes are not benevolent, whose administration is not just, and who has no delight in rectitude, purity, and mercy, (although we might not consider him like many of the heathen objects of worship, malignant, capricious, vindictive, and sensual,) cannot in the smallest degree be favourable to virtue, any more than atheism itself.

This remark leads us to examine another point which has often been discussed. Whether is atheism or superstition more subversive of morality, more injurious to private happiness, and more destructive of the peace and good order of society? We answer first, that those moderate degrees of superstition, which do not obliterate the primary sentiments of religion, do not necessarily weaken the obligations of morality. But every variety and gradation of atheism, whether absolute or indirect, has a pernicious tendency. In the next place, it may be observed, that the grosser forms of superstition are either

modifications of atheism, or lead directly to atheism; and therefore the effects may be expected to be in the same degree pernicious. Those superstitious persons, who divest the Deity of the attributes of justice and mercy and holiness, worship a being as unreal as fate or chance, and may probably be misled farther from their duty than others who are neither encouraged nor deterred by their belief. What the effects of atheism might be, if invested with power, has never been shewn by experiment. It has often been observed that an unaccountable degree of bigotry has been exemplified among this deluded class of men; and it is possible that if some of them had been armed with secular authority, their persecutions would have been not less sanguinary than those which have proceeded from the intolerance of fanaticism. The direful consequences of superstition, on the other hand, have often been manifested without disguise, because from its association with many civil establishments, it has claimed the support of law, and perpetrated its atrocities under the colour of justice.

Here we may remark, that Lord Bacon, in treating of atheism, utters a sentiment which has often been applauded, "I had rather believe all the fables in the Legend, the Talmud, and the Koran, than that this universal frame is without a mind." This declaration, we believe, will generally be understood to imply, that a superstitious belief is preferable to atheism. Yet in the next page he says, with greater correctness, that it were better to have no idea of God at all, than one that is unworthy of him; a sentiment borrowed from Plutarch. "Atheism," his lordship adds, "leaves a man to sense, to philosophy, to natural piety, to laws, to reputation, all which might be guides to outward moral virtue; but superstition dismounts all these.—Atheism did never perturb states; for it makes men wary of themselves, as looking no farther, &c." This is reasoning to very little purpose, especially if it be true that only two or three atheists have lived since the world began. But how could his lordship say, that atheism leaves men to sense, to piety, to philosophy, and that superstition robs them of these advantages, and almost in the same breath exclaim, that he would rather swallow all the superstitious stories which have arisen out of the corruptions of religion, than be an atheist; that is, rather be deprived of sense, of philosophy, piety, regard to law and character, than allowed to retain them. We would suggest farther, that the true reason why atheism has not convulsed states, is because this particular heresy is not very contagious, and has never become so epidemical as to muster its armies in the field. Hordes of stupid and irrational savages, have existed, it is said, who had never heard the name of a Deity, or even formed the idea in their minds; and the creeds of many ancient nations present a few traces of an enlightened belief. But this deplorable ignorance in which they were immersed, this negative atheism, could never be expected to operate as a principle of action, till it grew up into that monstrous complication of errors which obtains the name of superstition, and which is related in the same degree to atheism as mania is to melancholy.

Bayle has been censured for saying, that there have been atheists and Epicureans, who excelled most of their idolatrous contemporaries in good morals. He vindicates his assertion not only by appealing to the testimony of credible writers, but by accounting for

the fact. He shews that other principles, besides regard to the will of God, may restrain men from gross vices,—the love of praise, the fear of infamy, gentleness of natural disposition, and the restraint of human laws. The first which he mentions is unquestionably the strongest. The love of reputation is so powerful, as often to preponderate over every other impulse; and it is generally associated, in minds of a particular construction, with a romantic sense of honour, and a pride of appearing superior to the fear of punishment, or the hope of reward. The love of virtue for its own sake, is much insisted on by a certain class of writers, as a principle of the highest efficacy; but we cannot ascribe to it any very powerful influence over those, who have so far overcome the native feelings of their minds as to refuse to recognise the signatures of wise and benevolent design, imprinted on every department of nature.

We shall conclude by observing, that atheism has often been punished by the civil power as a crime of the most atrocious malignity. Justice and expediency equally demand, that penal laws relating to religion should be very sparingly enacted. It is certain that no crime can be more malignant than the attempt to propagate a belief which is so unfavourable to the well-being of human society, the happiness of life, and the hopes of futurity. Yet we cannot subscribe to the opinion, that none write so well against atheists as those who sign the warrant for their execution. It is always dangerous to punish men for sentiments which may be construed by others into a tendency to atheism. Whoever reflects on the condemnation of Anaxagoras, and the martyrdom of Socrates, will tremble at the prospect of having such a power lodged in the hands either of magistrates or churchmen, except when the impiety has been so audacious and unreserved, that there can be no room for hesitating concerning its reality. In such a case as this, when the denial of a God is openly avowed, we believe the most suitable punishment would be to devote the offender, as a dangerous maniac, to solitary confinement. Nothing but insanity of understanding, or still greater insanity of heart, can prompt any man to the atrocity of saying deliberately, there is no God; thus endeavouring to dissolve the firmest ties of morality, to abolish the strongest bonds of social order, and to rob the pious mind of its sweetest solace under the vexations of life, and of the animating prospect into the world to come.

We have purposely omitted taking notice of the objections which have been urged by some late sceptical writers against the argument for a Deity. They will come under our review with greater propriety, when we give an account of the lives and opinions of these authors. We have also passed over a number of particulars which we intended to adduce in support of the opinion we have advanced with regard to the doctrines of the persons whom we have named as atheists. We have even shortened the list considerably, that the article might not swell beyond the bounds we had prescribed to it.

We subjoin a short list of authors whose writings are calculated to act as an antidote to the poison of atheism.

Galen de Usu Partium. *Derham Physico-Theology.* *Ray, Wisdom of God.* *Clarke's Demonstration.* *Boyle of Final Causes.* *Bentley and others Sermons on Boyle's Lectures.* *Foster on Nat. Religion.* *Abernethy on the Attributes.* *Paley's Natural Theology.* (λ)

ATHELING, from the Saxon *æthel*, noble, was the title given by the Saxons to the presumptive heir of the crown. (j)

ATHEL or ÆTHELINGAY ISLE, or the ISLE OF NOBLES, a piece of rising ground in Somersetshire, formed into an island by the junction of the Thone with the Parrot, a little below Staunton. It is celebrated as the asylum of King Alfred for nearly twelve months, when the kingdom was overrun by the Danes. From this place, defended by marshes and inaccessible roads, Alfred made frequent sallies upon the Danes, and subsisted himself and his followers by plunder, till better prospects called him from this impregnable retreat. In this island Alfred afterwards founded a monastery of Benedictine monks, and conferred upon it very extensive privileges. Many antiquities were dug up here in 1674. See Hume's *History*, chap. ii. p. 83.; Collinson's *History of Somersetshire*; and ALFRED. (π)

ATHILLSTAN, one of the kings of England, and natural son of Edward the Elder, succeeded his father in 925. See Hume's *History*, chap. ii. p. 106.; Henry's *History*, vol. iii. p. 94. vol. iv. p. 225.; and ENGLAND. (w)

ATHENÆA, the name of festivals celebrated at Athens in honour of Minerva. See PANATHENÆA (j)

ATHENÆA, a genus of plants of the Class Octandria, and order Monogynia. See BOTANY. (w)

ATHENÆUM, a place of public resort at Athens dedicated to Minerva, and frequented by the poets, philosophers, and orators, who recited their compositions. The Athenæ were built in the form of an amphitheatre. The most celebrated buildings of this kind were at Athens, Rome, and Lyons. (j)

ATHENÆUS, a celebrated Greek grammarian. He was born at Naucratis in Egypt, and flourished, according to the most probable computation, in the beginning of the third century. Very little further is known concerning him. It has been erroneously inferred, from some passages in his writings, that he must have lived to an extreme old age, having been acquainted with the poet Pancrates, and lived after the time of Oppian. Now, though the former received some present from the Emperor Hadrian, who died A. D. 138, and the other dedicated a poem to Caracalla in the year 204, we see no reason for the inference of great age; since Pancrates might have lived 40 or 50 years after Hadrian, and since Oppian, who died of the plague at the age of 30, could not have long survived the date of his *Halicuties*. We can infer no more from these data, than that Athenæus was born towards the end of the second century, and flourished, not under Marcus Aurelius, as Suidas asserts, but in the interval between the reigns of Caracalla and Gordian.

The works of Athenæus have suffered severely in the general wreck of ancient literature. He is supposed to have written, "An Account of the Kings of Syria." Vossius thinks that he also wrote a treatise "concerning the great commanders of armies." The only work of his which has come down to us, is that entitled, "The Deipnosophists," or "The convivial Men of Learning." This work consisted originally of 15 books; but the two first, the beginning of the third, and several pages of the 11th and 15th, are wanting. These deficiencies, which occur in all the copies of Athenæus, are traced to one common source, the ancient Venetian manuscript, on which alone is supposed to have once depended the existence of the Deipnosophists. Fortunately

for the cause of literature, a very old, though inaccurate, abridgment of Athenæus has been preserved, out of which the lacunæ are tolerably well supplied, and even some false readings in the original corrected. This author has been most cruelly mangled by the transcribers and first editors: on his first appearance scarcely a sentence occurred which did not require emendation; and the labour of correcting the poetical quotations, which were long written without regard to the division into lines, appeared absolutely hopeless. Casaubon, and other critical pioneers, have wonderfully succeeded in clearing this thorny field; though, it must be confessed, it is still far from being an agreeable walk for an ordinary Greek scholar.

The plan of this work is somewhat whimsical. Athenæus feigns one Larensius, a learned Roman of opulence and taste, to have entertained at a splendid feast a company of the most distinguished literati, consisting of poets, physicians, lawyers, naturalists, and grammarians; and to these the different dishes and accompaniments serve, in their order, as topics of discussion. In this manner the author contrives to present, *ab ovo usque ad mala*, the opinions of the ancients in almost all their arts and sciences. Thus, the various kinds of fishes, pot-herbs, and poultry, are discussed: in the course of this hodgepodge conversation, historians, poets, and philosophers, are introduced: instruments of music, drinking-glasses and jokes, some of them not the most seemly, pass next in review; not to mention the disquisitions on regal magnificence, naval arts, and an infinity of other subjects. The whole of this strange production is thrown into a dramatic form; by which contrivance Athenæus, who was himself one of the Deipnosophists, is enabled to pass with facility from one dish to another, and to digress with seeming propriety, while replying to the remarks and queries of Timocrates, the other speaker in the dialogue.

Athenæus, considered as a man of talent and taste, occupies but a low station among the ancients. A mere collector of lines and sentences, and a plagiarist who borrowed whole passages from others to express his own meaning, he can be regarded only as a laborious unenlightened compiler: and in this view, there is no doubt, his cotemporaries considered him. But time and accident have conferred on this mechanical writer a degree of importance, which has raised him to a level with the classics. The crude mass of compilation which at one time would scarcely have been noticed, is now, from the destruction of better works, become a precious mine of information. On examining the catalogue of authors and works consulted by Athenæus in his multifarious researches, as it is drawn up by Fabricius, we find some hundred writers quoted, who no longer exist, and near 2000 pieces referred to, of which 800 are dramatic. This wonderful collection of literature was accordingly greedily attacked by the succeeding bookmakers. Ælian frequently copies it in silence: Macrobius, in his *Saturnalia*, adopts at once its plan and its materials; and Suidas Eustathius, Stephanus Niger, and many more, have pillaged and appropriated, with shameless audacity, the rich treasures of Athenæus.

Of this author there have not been many editions. The first was that of Aldus, in folio, printed at Venice, in 1514. Another edition appeared in 1535 at Basle, which, like the former, was accompanied with neither translation nor notes, and was besides exceedingly incorrect. The first edition of any value was that of Ca-

saubon of 1597, which went through several impressions. This edition had the Latin translation of Dalechampi, and the admirable annotations of Casaubon; and still further corrected and enlarged, it again appeared in 1657, 2 tom. 1 vol. Lugd. which is the edition now before us. The Strasburg edition of 1801, by Schweighæuser, we have not yet seen.

There have been several other writers of less note who bore the same name. Athenæus, the mathematician, who flourished about A. C. 200, wrote a treatise on machines, which he dedicated to Marcellus the conqueror of Syracuse, and which still remains. Athenæus Attalensis was a physician, who ascribed the human pulse to the agency of a spirit, or principle of vitality, which he supposed to be a fifth element in nature. He was the chief of the Pneumatic sect, and flourished about the beginning of our æra.

See *Athenæus*, Ed. Ludg. 1657, p. 1. *Suid. Lexic. Tan. Fab.* ch. 43. *Diction. de Bayle. Fabricii Bib. Græc.* l. iii. c. 24. l. iv. c. 20. *Edin. Review*, vol. iii. (E)

ATHENAGORAS, an Athenian philosopher, who was converted from paganism to Christianity. He flourished after the middle of the second century, and was held by his cotemporaries in high estimation for his learning, acuteness, and zeal. Having spent his youth at Athens in the company of the sages and rhetoricians of that period, he removed to Alexandria, then a great theatre of learning. Here our philosopher keenly entered into the disputes of the time, and directed the whole torrent of his eloquence and erudition against Christianity. Deeming it necessary to acquire a thorough knowledge of the system which he intended to overthrow, he applied himself with eagerness to the reading of the scriptures. His candour, if we may judge from appearances, was equal to his zeal, and infinitely superior to that of most controversialists either ancient or modern. For on carefully perusing the sacred volume, reflecting on the important and long-desired discoveries which it contains, and weighing impartially the arguments of the primitive fathers against the absurdities of polytheism; this true philosopher became a convert to the reason of his antagonists, and thenceforward became a powerful champion of the cross. He is said to have been the founder of the Alexandrian school, and to have had Clemens Alexandrinus among his disciples.

The church being about this time greatly oppressed in the East, Athenagoras wrote a remonstrance on the subject, addressed to the emperors Marcus Aurelius Antoninus, and Lucius Aurelius Commodus. This remonstrance, containing the principles of Christianity, and a justification of secession from paganism, was presented, according to the opinion of some writers, by Athenagoras in person, who, it is asserted, had for that purpose been sent at the head of an embassy to the imperial court, about A. D. 168. Others however reject this opinion, on the grounds that such an embassy is not once alluded to in history; that the common title of the piece (*πρεσβεία*) is in some manuscripts *απολογία*, or "defence;" and that even *πρεσβεία*, which may signify "request" as well as "embassy," is never applied to the instructions of an ambassador, but to his mission. Be this however as it will, the apology or embassy still exists, and is couched in language of considerable elegance. The frequent inversions and parentheses betray, a little too sensibly, the art of the rhetorician: the

epithets, too, bestowed on the emperors, are unwarrantably strained, and bordering even on blasphemy; but with all these defects, which indeed belong to the period rather than to the man, the style has undoubted pretensions to the character of Attic; and the train of reasoning, particularly in exposing the pagan superstition, is remarkably forcible and happy. Athenagoras wrote also a book on "The Resurrection of the Dead." In this treatise, which is also preserved, the author properly confines himself chiefly to mere reason, since in a controversy with infidels, an appeal to scripture were evidently fruitless.

The Platonic philosophy influenced, in no small degree, the theological tenets of Athenagoras. He endeavoured to explain, on the principles of that school, the nature of the Deity, the particular energy of the Logos in the divine mind, and the eternal and necessary coexistence of the Father and the Son. He maintained, in opposition to the Peripatetics and others, the entire and absolute distinction between God and matter; and he supposed that these two principles, one spiritual and intelligent, the other imperfect and untractable, were connected by intermediate existences, partaking of the nature of both. These beings he considered as good or evil according as spirit or matter predominated. The evil kind he further subdivided into two classes, of which one consisted of those angels who originally transgressed the divine command; and the other, of the souls of those giants who were produced by the intercourse of the angels with the daughters of men. This philosopher was one of those who recommended and practised celibacy as a piece of meritorious mortification, and viewed second marriages with the utmost abhorrence. Altogether, the writings of Athenagoras savour strongly of that subtlety which distinguished the Grecian schools. He never, it is said, could sink the lofty philosopher into the plain Christian, but retained, even in his dress, the badges of that profession to which he had been educated.

The two remaining treatises of Athenagoras have undergone many impressions, of which the reader will find a long list in Fabricius. The best is that published at Oxford in 1706. The romance, entitled, "True and Perfect Love," has, we know not why, been ascribed to the same Athenagoras. It is for the most part but a compilation of passages from Herodotus, Plutarch, Q. Curtius, Jamblichus, and Heliodorus, and has all the appearance of being the production of some modern Greek. There are ten or twelve more of the same name mentioned by authors; but few of them are of any note.

ATHENODORUS, an eminent Stoic philosopher, and the intimate friend of Augustus. He was born at a village near Tarsus, in Cilicia, whence he obtained the surname of Cananita. When young, he displayed a remarkable instance of generosity. His brother being convicted of a crime for which his property was confiscated, Athenodorus gave him the half of his; and overlooking the ingratitude with which he received it, continued to treat him with unabated kindness. On going to Rome, the excellence of his character procured for him the friendship of Augustus, that discerning

patron of merit; who loaded him with honours, and made him preceptor to Tiberius.

Being indulged by the emperor with an unlimited freedom of expressing his sentiments, he availed himself of this liberty, on one occasion, in rather an extraordinary manner. It happened one day that Athenodorus met a senator of his acquaintance, who was thrown into the greatest alarm, because the emperor had sent for his wife, who was remarkable for her beauty. Nobody, it seems, ever thought of resisting such a mandate; so formidable was the tyrant's resentment. But the philosopher resolved to give him a strong hint; for arming himself with a naked sword, and slipping into the chair instead of the lady, he was thus carried into the presence of Augustus. Athenodorus rushed out of the chair, and furiously brandishing the sword, seemed to be on the point of dispatching him. The emperor was at first greatly terrified; but on learning the intention, he received the admonition with much deference, and behaved, it is said, more prudently for the future.

Having continued at court till he was far advanced in years, Athenodorus obtained permission to return to his native country. Before he went away, he advised Augustus to be on his guard against anger; recommending to him, whenever he felt the commencement of that passion, to repeat the four-and-twenty letters of the alphabet: upon which, the emperor, taking him by the hand, said to him in the kindest manner, "I have need of your assistance still longer:" and he kept him for another year.

On his departure he seems to have been invested with some authority over his native country; for, on his arrival, he took an active part in the government of Tarsus: he reformed abuses, expelled one Boetus and his partizans, introduced a new code of laws, and obtained from Augustus an exemption from certain taxes which oppressed the inhabitants; for which service he was honoured by his countrymen with an annual festival. He is said to have died at the age of 82. He wrote concerning the ocean and its tides; and is thought to have written a history of his own country: but all his works have perished.

There were several other writers of the same name, particularly a famous Stoic philosopher, surnamed Cordylio. He kept the great library at Pergamus, where he continued till he arrived at a considerable age. Cato the younger, being in Asia at the head of his army, wished above all things to have the countenance of this great man: but fearing that a letter would not answer the purpose, he went to Pergamus in person, and prevailed, with some difficulty, on the old philosopher to quit his retirement. Cato returned to his camp with an air of triumph on the acquisition of Athenodorus to his party, which he deemed of more consequence than a victory.

ATHENS,

ONE of the most celebrated cities of Greece, and of the ancient world. This distinction is derived, not merely from political greatness and military power, but from the arts and sciences, which were indebted to her, either for their origin, or their perfection. Athens, properly, is only the capital of ATTICA, a description of which will be found under its proper head. But as the name of the city has greatly eclipsed that of the territory to which it is attached, and as the inhabitants have always borne the appellation of Athenians, we shall give, under the present head, a sketch of the various fortunes of that renowned people.

Concerning the early inhabitants of this country, we are almost wholly destitute of information. Devoid of arts and letters, they left no memorials of their existence, or of those rude incidents by which their history may have been diversified. Their condition probably resembled that which we now see in the savages of north and south America.

Even after Athenian history begins to emerge from this profound obscurity, the events which distinguish it are, for a long time, exceedingly scanty and doubtful. It may not be uninteresting, however, to take a rapid survey, even of these imperfect traditions; since they throw some light on the origin and progress of the political constitution of Athens, and some also on the invention of the useful arts, the most important of which are, by the uniform voice of history, referred to this period.

The first king of Athens, of whom we have any mention, is Ogyges, from whom Attica received the name of Ogygia. He himself, or another of the same name, is supposed also to have reigned over Bœotia. His reign

seems to have been distinguished by a variety of religious institutions, by the aid of which he probably sought, like most other early legislators, to strengthen the ties of civil authority. He founded Eleusis, so famous for the mystic rites which were celebrated there; and it was in his reign that Minerva first became the tutelary deity of Athens. It is also marked by an inundation, which was productive of great calamities to Attica.

During the 300 years which elapsed from this period to the reign of Cecrops, the history of Attica is buried in complete obscurity. It is even doubtful whether it was then governed by kings, or was not involved in a state of anarchy. According to the most prevailing opinion, Cecrops came about the year 1556 A. C. from Egypt, a country then far surpassing Greece in opulence and civilization. Either by marrying the daughter of the preceding monarch, or by the favour of the people, he became the sovereign and legislator of Athens. He enlarged it greatly, converting the former town into a citadel, which ever after retained from him the name of Cecropia. He instituted marriage, which had not before been regulated by any fixed laws, and prohibited polygamy. Like other early legislators, he established a variety of religious ceremonies; introduced the worship of Ops and Saturn, and augmented that of Jupiter and Minerva. He was succeeded by Cranaus, a wealthy citizen, who is supposed to have married his daughter. Cranaus, however, after a short reign, was driven from the throne by his son-in-law, Amphictyon. He had a son Rharus, by whom Ceres, in her wandering search of her daughter Proserpine, is said to have been receiv-

ed, and in gratitude, to have taught his nephew Triptolemus the art of raising grain. Without stopping to enquire into the degree of truth which this relation may possess, we may probably hence infer, that agriculture was, about this period, introduced into Attica. Either Amphictyon, or a near relation of his, is understood to have taken the lead in forming that general assembly of Greece, so celebrated under the name of Amphictyonic. Amphictyon first dedicated the city to Minerva, and from her gave it the name of Athens. He is said to have introduced and inculcated the practice of diluting wine with water. The invention of wine is referred nearly to this period; and we may suppose its first introduction to have been attended with disorders, which it was the object of this regulation to check. Amphictyon, after a reign of ten years, was deposed by Erichthonius, the reputed son of Vulcan. He is said to have been the inventor of horse and chariot races. His successor was Pandion I., celebrated in fable for the misfortunes of his daughters, Progne and Philomela. Under his reign is placed the arrival and deification of Ceres in Attica. Erectheus, his successor, is generally supposed to have been the son of Pandion, though others represent him as an Egyptian, who, having brought a seasonable supply of corn, was, in gratitude, saluted king by the people. He reigned fifty years, and is said to have been the most powerful prince of his time. His reign is celebrated for the barbarous sacrifice of one or more of his daughters, which was demanded by the oracle as the condition of his victory over the Eteusians. Under the next king, Cecrops II., it appears that Attica had so much increased in population and wealth, that the mode of living in habitations scattered over the country was no longer suited to it. Twelve towns were therefore built in different quarters, in which part of the nation was settled. After the reign of his son Pandion II., which is distinguished by nothing remarkable, Ægeus came to the throne. This prince having gone to the oracle at Delphi, to enquire the cause and remedy of some disasters which were afflicting his people, on his return had an amour with Æthra, daughter to Pittheus, who then reigned at Træzene. Of this connection the fruit was Theseus, a name which ranks next to that of Hercules, among the heroes and demigods of Greece. Ægeus, on his departure, is said to have led his mistress to a sequestered spot, where, having deposited a hunting sword and a pair of sandals, he covered them beneath a great stone, and desired her, when her child should arrive at such an age, as to be able to lift that stone, to send him, with the tokens concealed under it, to Athens. The arrangement took place as appointed; and Theseus, having arrived at Athens, was recognized by his hunting knife, and owned by Ægeus. Either by war or negotiation, he then freed Athens from the shameful tribute of seven youths and seven virgins, which had been imposed by Minos king of Crete. On the death of his father, therefore, which took place in consequence of an unfortunate mistake in the signals held out on his return, the Athenians readily saluted him king. Having already distinguished himself as a warrior, he now acquired fame as a legislator. He abolished all the independent authorities established in the twelve districts, into which Cecrops had divided Attica, and which had rendered that country little more than a collection of detached states. In return, he communicated to all the privileges of Athenian citizens, and concentrated in Athens all the legislative and judicial authority. He instituted the festival called *Panathænea*, as a bond to unite the

whole Athenian people. He divided the inhabitants into three classes, nobles, husbandmen, and artificers. To the former was assigned the superintendance of religious ceremonies, the administration of the laws, and the appointment of magistrates. The people received a share in the legislature: he is said to have divested himself of a large portion of the regal power, retaining only the command of the army, and some share in the executive. This sacrifice is commonly celebrated as an unparalleled display of patriotism; but here we must own ourselves somewhat sceptical. That such a step should be altogether voluntary seems hardly consistent with the general character of human nature. From other circumstances it appears, that the people were becoming daily more jealous of the sovereign authority, and were with difficulty kept in subjection. Theseus, being almost an elective monarch, would be under the necessity of courting them; so that it appears probable, that in enlarging their power, he merely acted with a prudent accommodation to his own situation, and the circumstances of the times.

The rest of the life of Theseus is rather personal to himself, than connected with the history of Athens. Intoxicated with prosperity, he appears, towards the end of it, to have indulged in irregularities, which lost him the confidence of the people, and drove him into exile. His immediate successors, Mnætheus and Demophon, went successively to the Trojan war, and the latter is said to have been one of those inclosed in the wooden horse.

Nothing remarkable occurs till the reign of Codrus. This prince is immortalized by the heroic sacrifice, dictated by superstition, by which he effected the deliverance of Athens from a formidable invasion. This deliverance had, by the Delphic oracle, been attached to the condition, that the Athenian king should die by the hands of the enemy. Codrus, having insinuated himself into the hostile camp, picked a quarrel with a private soldier there, and suffered himself to be slain. The prophecy produced its own accomplishment. The enemy, disheartened and hopeless of success, retreated into their own country. The Athenians, who had long been jealous of the power of their kings, took this opportunity to abolish a title which had become odious. That of Archon was substituted.

The following is a chronological list of Athenian kings, and their reigns, according to Meursius.

	Years.
Ogyges, who reigned	52
Interregnum, which lasted	190
Cecrops, who reigned	35
Cranæus	9
Amphictyon	10
Erichthonius	50
Pandion I.	40
Erectheus	50
Cecrops II.	40
Pandion II.	25
Ægeus	48
Theseus	30
Mnætheus	23
Demophon	33
Oxyntes	12
Aphydas	1
Thymætes	8
Melanthus	57
Codrus	21

It may be observed that considerable doubts are entertained with regard to the existence of Cærops II., and Pandion II., and that the actions ascribed to them are by many referred to the first of their name.

After the establishment of the title of archon, for more than 200 years, a singular silence of history takes place. The names only of those who bore it have been transmitted to us, Melon, Acastus, Arhippus, Thersippus, Phorbas, Megacles, Diognetus, Pherceus, Aripbron, Thespius, Agamestor, Æschylus, Alceon. On the death of this last, the archonship was limited to ten years, and after passing, on this footing through six hands, a still greater change took place. The office was made annual, and was divided among nine persons, who were to be chosen by the people, but only out of the class of *eupatrids*, or nobles. One was first in dignity, and gave his name to the year. The second, under the title of king, presided over religious rites. The polemarch, at the first institution, had the superintendance of every thing which related to war. The remaining six, called *thesmothetæ*, exercised the judicial power. The government became thus almost a complete aristocracy, with a mixture, as yet small, of democracy. Such a form of government was, however, peculiarly exposed to party spirit, and contentions for power; these accordingly soon began to shew themselves. The Alceonids, descendants of the last perpetual archon, commanding, by their birth, a superiority of respect, Cylon, a young man of distinction, indignant at this preference, seized upon the citadel, with a party of his adherents. He was obliged to fly, and his companions, in spite of an oath to the contrary, were condemned and executed; but the impiety of this action brought thenceforth an odium on the opposite party.

Faction and discord, however, continuing to rage, a desire arose to remedy them by the institution of written laws, and Draco was chosen as the lawgiver. This person, unexperienced in his office, and viewing only the violence and disorder which prevailed, sought to remedy them by a blind and indiscriminate severity. To every offence, without distinction, he awarded the punishment of death, declaring, that "small faults seemed to him worthy of death, and for flagrant offences he could find no higher punishment." The atrocity of this code was soon found to render it incapable of execution; Draco lost the public favour, and died in exile.

This attempt having proved ineffectual, public disturbances continued to increase. The people acquired more and more influence in the government, and mingling themselves with the parties among the higher orders, increased the confusion. It was still exasperated by the inequality of property, and the disputes between debtors and creditors, an eternal source of discord in the ancient commonwealths. Under these circumstances, the necessity for a new legislator was felt, and all eyes were turned towards Solon. This person had already distinguished himself in a very singular manner. Salamis had revolted from the Athenians; and the people had been so dissatisfied with several unsuccessful attempts to reduce that island, that they tumultuously assembled, and passed an edict, inflicting the pain of death on any one who should propose farther measures to that effect. The nobility were highly indignant, and the people themselves became ashamed of their proceeding; but no one durst propose to retract it. In these circumstances, Solon determined to counterfeit

madness; and rushing into the market-place in a fantastic attire, recited a song, in which he lamented the disgrace of the Athenian name by the loss of Salamis, and urged his countrymen to efface it. The expedient prevailed; an expedition against Salamis was decreed, and Solon, being appointed commander, made himself master of the island by a skillful stratagem.

In the business of legislation, however, Solon was preceded by Epimenides, a Cretan, who was invited to Athens, where he introduced a variety of religious ceremonies, then ordinary instruments for holding the minds of men in subjection. The good effects of these, however, disappearing with himself, Solon was soon after called upon to make a radical change in the constitution of the state.

The foundation of the system which he established was laid in the supreme power, both legislative, executive, and judicial, vested in the assembly of the people. By them all laws were enacted; every public measure was determined; and to them an appeal lay from all courts of justice; they appointed to all commands. After bestowing on them such powers, it was vain to attempt imposing any limitations on their authority. The supreme legislators were always able to break down any barrier which might oppose their inclinations; and as every member of the state was interested in courting their favour, there would be no want of persons to instigate them to such measures.

Solon, however, in laying down the original plan of the constitution, seems anxiously to have studied to provide a balance against that extreme power of the popular assembly, which he granted less perhaps from his own inclination, than from finding them already the predominant order, possessing both the inclination and ability to assert their claim to it. Upon the higher ranks he conferred the exclusive right to fill all offices in the state, and all commands in the army and navy. He divided the citizens into four classes, according to their wealth. The first class consisted of those who had an income of 500 medimni, or measures of corn; these paid a talent into the public treasury. The second was of those who possessed 300 measures; these kept a horse, and served in the cavalry; they were thence called *Hippicis*, or knights. The third, possessing 200 measures, were called *Zeugites*, and served in the heavy armed foot. All under this were only called upon to serve in the light armed foot, a description of force little respected among the Greeks, who sought, on every occasion, to come to close combat. Such of them, however, as chose to afford the expense, might rank with the heavy armed. A very large proportion went on board the fleet, which was chiefly manned by this order, and which became afterwards a most eligible and lucrative service.

All magistracies, and all commands in the army and navy, could be filled only by the three first orders. It does not appear that this exclusion of the lower orders, which, at Rome, formed the grand source of popular discontent, was considered as a serious grievance at Athens. These offices, from the small salary annexed to them, and from the necessity of courting and feasting the people, were extremely expensive, and could not be filled but by persons who possessed a considerable income. The fourth class had, what was of more value to them, an equal vote in the public assembly; in which, from the superiority of their number, they soon bore down all opposition, and became the sovereign.

people of Athens. They were also entitled to sit on juries, which were very numerous.

The office of archon still subsisted, and was held in high respect, but without any political importance attached to it. A certain qualification, not only of fortune, but of birth, was requisite for the attainment of this office. They were nine in number, chosen by lot. The first, and principal, was called *Eponymos*: He had an extensive judicial authority, to which was added the regulation of the plays and festivals. The second, who was called *Basileus*, or king, had the superintendance of all religious ceremonies. Originally, throughout all Greece, while the office of king subsisted, this formed part of his prerogative; and, in consequence of the dislike to innovation in religious matters, even after the office was abolished, the title was still retained for this particular purpose. The third, the *Polemarch*, had originally the superintendance of military affairs; but his jurisdiction was afterwards confined to strangers, and the regulation of some festivals. The remaining six were called *Thesmothetæ*: their office was judicial; and they had the charge of drawing up some reports relative to any proposed legislative changes. See ARCHON.

Besides this exclusive admission to offices, Solon employed other means of elevating the aristocracy. Of them the Athenian senate was exclusively composed. This body consisted originally of four hundred; one hundred from each of the four wards into which Athens was divided: but, when the wards were increased to ten, each of them sent fifty, which raised the number of the senate to five hundred. These members were chosen by lot. Before entering on their office, they underwent a strict examination, which extended to every part of their previous life and conduct; and a similar scrutiny took place on their leaving office, respecting the manner in which they had conducted themselves in the exercise of it. No proposal for a new law could be made to the assembly of the people, without having first passed through their hands. They were bound, however, to receive a proposal from any citizen; nor does it appear that, like the Scottish lords of Articles, they had any power of withholding such as were disagreeable to them. They met once a day, or oftener. Out of the number of four hundred, fifty were chosen, who were called *prytanes*, and performed, ten in the week, by turns, the office of presidents. These ten were called *proedri*, and chose, by lot, an *epistate*, or first president. From these the senate-house was called *prytaneum*. The senate had a considerable superintendance over different branches of administration; but, upon the whole, their political power seems not to have been great, nor do we find their name often mentioned in the course of Athenian history.

When any law had been digested in the senate, a *prographma*, or statement of its nature, was posted up in some public situation. On the day of assembly, the *epistate*, or first president, came, accompanied by the rest of the *prytanes*, and read the decree of the senate, on which they were to deliberate. He then called out, "Who above fifty chooses to speak?" When these had done, he cried, "Any one not disqualified by law might speak." The disqualifications were, the having fled from their colours, the being indebted to the public, or being convicted of some flagitious crime. The vote was given by casting beans, and afterwards pebbles, into a vessel. The assembly met four times in thirty-five days. In the first, they deliberated on the general con-

cerns of the state, and elected magistrates; in the second, they received appeals from the different courts of justice; in the third, they gave audience to foreign ambassadors; the fourth was appropriated to the offices of religion. Besides these ordinary assemblies, however, extraordinary ones could be, and were frequently, called by the magistrates, on any pressing emergency.

Another counterpoise to the preponderance of the people was provided by Solon, in the court of Areopagus, whose power had been considerably reduced by Draco, but which the present legislator had restored to all its former privileges. This is the most respectable court of justice known in ancient times. It consisted of those archons who had filled their office with the greatest credit, and had stood an examination of peculiar strictness. But their high character seems especially to have arisen from the circumstance of having been the first judicial body, which was independent both of the legislative and executive powers. The members continued during life. They had also an extensive censorial power, and a large share in the management of the treasury. Pericles, with the view of courting the people, abridged very much their power, a change which was by no means advantageous to the constitution. See AREOPAGUS.

Besides regulating the political constitution of Athens, Solon established also a body of laws, which have served as the basis of all subsequent systems of legislation. He mitigated the severity of those of Draco. Like most of the ancient legislators, he entered deep into the concerns of private life. Strict sumptuary regulations were enacted. The ceremonies to be observed, and the dress to be worn, at marriages and funerals, were particularly enumerated. Industry and economy were strictly enforced. No person was allowed to remain in Athens who could not shew the manner in which he obtained his livelihood; the father who had not taught his son a trade, could not claim support from him in his old age; and he who had wasted his patrimony, was declared incapable of rising to any public honours. Ingratitude, opprobrious language, and disobedience to parents, were also subjected to punishment.

One of the most remarkable laws was that which imposed penalties on those who declined taking part in public dissensions. Solon was aware, that such dissensions must occur in a popular state; but, on these occasions, the wisest and best men are often disposed to withdraw into domestic life, and shun the public tumult. The management of the state would thus fall into the hands of the most ignorant and unprincipled. To prevent this evil, it appeared expedient to make a regulation which might draw the former class out of the retirement to which they were naturally inclined, and force them to engage in the management of public affairs.

Having completed his system, Solon adopted a policy which seems to have been general at that time, and was also employed by Lycurgus. He left Athens, to which he did not return for the space of ten years. The experiment, however, was not fortunate; the tranquillity which he had established, seems to have been the fruit rather of his personal influence, than of the authority of his laws. On his departure, factions broke out, with all their former violence. Lycurgus was at the head of the country, or aristocratical party; Megacles, the chief of the Alcmeonids, supported the party of the principal in-

habitants of the city, who were for a mixed government; Pisistratus was the leader of the purely democratical party, which consisted of the highlanders, and of the lower orders in the city. He courted popularity by every method with which a large fortune and engaging manners could furnish him. He lavished money on the necessitous, and conversed familiarly with all. Thus he silently made his advances to the sovereignty. At length, when his plans appeared ripe, he one day made his entry into the market-place, wounded, and flying, as it were, from pursuing enemies. The people being immediately assembled, one of his friends moved, that a guard should be appointed to attend him. With this he contrived to make himself master of the citadel; and it is also said, that, by a stratagem, he deprived the people of the arms which they were accustomed to wear. He ruled however mildly, observing all the outward forms of liberty, and enforcing the execution of Solon's laws. Solon was his intimate friend, and fully admitted his merits, but opposed, to the utmost, the establishment of his tyranny. This last account, however, though conformable to the general voice of antiquity, is not considered by Mr Mitford as resting on any very solid evidence. It would appear, indeed, that Pisistratus ruled at first more by opinion than by force; for the heads of the two opposite parties, Lycurgus and Megacles, having coalesced against him, he was obliged to leave the city. The victorious factions, however, could not agree among themselves, and Megacles called in the aid of Pisistratus, in order to expel his rival. The manner in which they accomplished their purpose, however singular it may appear to us, was not ill suited to the ideas of the age. A woman of a majestic figure was dressed in the manner of the goddess Minerva; and the report was spread, that this deity was reconducting Pisistratus to Athens. The people, who probably regretted his absence, readily acknowledged the pretended goddess, and restored him to all his former authority.

Pisistratus, in consideration of this service, had promised to marry the daughter of Megacles, which promise he performed; but conceiving himself now independent of that leader, he ceased to court his favour, and treated his wife in so contemptuous a manner, as irritated her brother in the highest degree. Megacles accordingly again connected himself with the exiled party, and was thus enabled to expel Pisistratus a second time. The latter, however, now determined to assert his claims by force. Possessing, it would appear, considerable interest in Greece, he contrived to raise an army, at the head of which he returned, beat his adversaries, and again assumed the government of the state. He used his victory, however, with the utmost moderation: He inflicted no punishment on those who submitted: He still maintained the laws and government on their ancient foundation. So strictly observant was he of the forms of the republic, that, on one occasion, he allowed himself to be tried for his life before the court of Areopagus. He seems to have done much to polish the character of the Athenians, and to introduce that ardent cultivation of the arts and sciences, which afterwards rendered their name so celebrated. He collected the poems of Homer, which before were merely repeated in scattered rhapsodies. He distinguished himself by military exploits, of which, however, no detailed account has been transmitted to us. In short, he appears to have merited the character of Solon, that, had it not been for his ambition, he would have been the best citizen of Athens. From the time

of his first assuming the government till his death, thirty-three years had elapsed; but, reckoning from his ultimate and forcible seizure of sovereignty, he reigned only seventeen.

His sons, Hippias and Hipparchus, succeeded him. It is not ascertained which was the eldest, but it appears that they reigned jointly. They seem to have been persons of singular accomplishments. They inherited all their father's love for the arts and sciences. Hipparchus is particularly celebrated for the excellence of his character. Simonides, Anacreon, and other poets, were his intimate friends, and constantly near his person. But the Athenians were now become weary of servitude, however mild, and were ready to grasp at any opportunity of regaining their independence. Such an opportunity soon occurred. Two friends, Harmodius and Aristogiton, conceived an enmity against Hipparchus, not originating in very honourable motives on either side. They took the opportunity of the approaching festival of the Panathenea to assassinate him, expecting that the people, who were then allowed to appear armed, would espouse their cause. This hope was disappointed: Harmodius was dispatched on the spot, and Aristogiton seized. The action of these two persons seems to have been prompted by private, and not the most honourable motives; yet such was the passion of the Athenians for liberty, that their names have been, as it were, canonized and transmitted to posterity as the most perfect models of friendship and patriotism.

Aristogiton, on being apprehended, was immediately put to the torture. His conduct on this occasion is remarkable: Instead of betraying his real accomplices, he named the best friends of Hippias. It is said, that, after going over several, and being asked if there were any more, he replied, "I know of yourself only now, that deserves to suffer death."

Hippias, from this moment, became really a tyrant. The dread of sharing the fate of his brother tormented him with continual suspicion. Many of the principal men were put to death, and the Athenians, to whom the tyranny before had begun to be burdensome, beheld it now with the utmost detestation. Meanwhile the Alcmeonids, who, with their leader Megacles, had been expelled at the last usurpation of Pisistratus, were straining every nerve to effect a return into their native country. Being possessed of very considerable wealth, they rebuilt the temple of Delphi, which had been accidentally burnt; and they executed this work in a manner which rendered the edifice more splendid than ever. This was a service generally acceptable to Greece; and they contrived, in another way, to render it still more subservient to their interests. They gained the priestess, who, whenever consulted by the Lacedemonians, ceased not urging them to restore the liberty of Athens. The Lacedemonians, dreading the resentment of the deity, with which they were threatened, and not unwilling, perhaps, to avail themselves of this opportunity of extending their influence, at last determined to obey the oracle. They sent an army by sea into Attica; but Hippias, with the aid of his Thessalian auxiliaries, routed and drove them back to their ships. The Lacedemonians, however, were not discouraged, but determined on extraordinary exertions to wipe off this disgrace. Next year they sent by land a large army, under their king Cleomenes. The Thessalians were routed, and Hippias constrained to take refuge within the walls of the city. Here, however, he might have successfully

resisted, had not his children accidentally fallen into the hands of the enemy. To redeem them, he consented to abdicate the tyranny.

Athens was then reinstated in the liberty of which she was so ambitious. Faction, the usual consequence, soon followed. Clisthenes, now the leader of the Alcmeonids, was at the head of the one; Isagoras, son of Tirsander, of the other. These two parties were the same which, from this time, divided all the Grecian states; the aristocratical and the popular. To the former Isagoras attached himself, while Clisthenes sought to rise by paying court to the people. The popular party was henceforth destined to rule in Athens; and Clisthenes, through them, soon acquired a decisive superiority. Isagoras, finding himself unequal to contend with his rival, applied for aid to the Lacedemonians. That people, in consequence of having expelled the Pisistratidæ, conceived themselves to have a right to interfere in the internal concerns of Athens: Cleomenes accordingly set out with an army, and sent before him an order to banish Clisthenes out of the republic. The Athenians, not yet aware of their own strength, complied. Cleomenes, however, soon shewed, that this was not the only object he had in view. He advanced to Athens, and conducted himself there in the most arbitrary manner, banishing seven hundred families, and seeking to vest the whole authority in 300 of the partizans of Isagoras. This was too much for the Athenians; they instantly took up arms, drove out Cleomenes and the partizans of Isagoras, constrained them to take refuge in the citadel, and kept them there closely blockaded. Cleomenes now found himself so hard pressed, that he consented to surrender the citadel, and evacuate Attica. Clisthenes was then recalled, and all the power again centered in the people.

Cleomenes, meanwhile, spared no exertion to assemble an army, which might repair his disgrace. To the Spartan troops he united those of the Corinthians, and other allies, and marched with a formidable army towards Attica. At the same time the Bœotians prepared to invade it from a different quarter, seconded by the Chalcidians, a people of Eubœa. The Athenians, at this critical juncture, displayed all that promptitude and energy, of which they afterwards gave so many signal examples. Not having forces to engage so many enemies at once, they marched first with their whole army against the Lacedemonians, leaving, for the time, Attica at the mercy of the Bœotians and Chalcidians. In this first undertaking, they prevailed without the hazard of a battle. The Corinthians, either affected with scruples as to the justice of the cause, or intimidated by the great force opposed to them, broke up, and returned home. Their example was followed by the rest of the allies; even the colleague of Cleomenes opposed the prosecution of the undertaking; so that he found himself under the mortifying necessity of returning home with the Spartan troops.

The Athenians lost no time in improving this success to crush their other enemies. The Chalcidians appear to have been on the point of forming a junction with the Bœotians, and had advanced, with that view, to the other side of the narrow channel of the Euripus, which separates Eubœa from the continent. The Athenian army, however, advanced with such expedition, that before the junction could be effected, they attacked and routed the Bœotians; then immediately crossing the Euripus, engaged, and on the very same day completely defeated

the Chalcidians. After this double victory, they returned in triumph to Athens.

About this time, the Athenians were engaged in a long war with the inhabitants of Ægina, not productive of any memorable events, but important as having first turned their attention to the formation of a maritime force. See ÆGINA.

These petty contests, however, were soon lost in another of far greater magnitude, which was destined to raise Athens to the summit of glory. The Ionians were the most flourishing of the Grecian colonies in Asia Minor. Like the others, they had originally enjoyed liberty, but had sunk under the overwhelming might of the Persian empire, and been compelled to acknowledge its supremacy. They bore the yoke, however, with impatience; and being excited by their chiefs, Histæus and Aristagoras, they took up arms, and engaged in war with Persia. Sensible, however, that they could not alone resist the force of so mighty an empire, they looked for aid to the states of their mother country. They applied first to Lacedemon, then considered as the leading city of Greece; but that cautious government declined interfering in so arduous an undertaking. Their ambassadors then proceeded to Athens, which, since its recent exploits, had taken a prominent station among the powers of Greece. That people, always enterprising and ready, without weighing consequences, to embark in any promising scheme, agreed to give their assistance, and sent 20 galleys, with troops on board, which were joined by five from Eretria, a town of Eubœa. On their arrival at Miletus, it was proposed to them to engage in an expedition to plunder Sardis, the wealthy capital of Lydia. In this enterprize they embarked with eagerness; the confederates, by a rapid march, found Sardis unprepared, and immediately proceeded to plunder. But while they were busied in this occupation, the Persians rallied, surprised them in their turn, and drove them out of the town. The confederates now made a precipitate retreat to the coast, but even this did not preserve them from Persian vengeance. The army of the great king came up with them at Ephesus, and after an obstinate engagement, totally defeated them. In consequence of this disaster, dissensions arose among the confederates, and the Athenians returned home, abandoning the cause of their unfortunate allies. Such was the issue of their first contest with the Persian arms, which certainly did not prognosticate that splendid success, with which their enterprises were afterwards crowned.

This affair directed the eyes of the Persian monarch towards Greece, both as an object of resentment and of ambition. His first step was to send round heralds to the different states, demanding earth and water, the usual tokens of submission. All, overawed by the power of Persia, complied, excepting Athens and Lacedemon. These two cities, with a barbarous patriotism, threw the ambassadors into wells, and casting earth upon them, declared, that they had now obtained their demand.

Darius, who then reigned in Persia, proceeded now to more formidable measures. Mardonius was first sent with a large army to cross the Hellespont, and attack the northern districts; but a violent storm having dispersed his fleet, he returned without effecting any thing of importance. A new plan was then arranged. An immense fleet and army having been assembled, it was

determined to transport them from the shore of the Lesser Asia, and to land them, first in the island of Eubœa; after having subdued which, and signally punished the Eretrians, they might pass over into Attica. Mardonius, who had been at least unfortunate, was superseded, and the command given to Datis and Artaphernes; the one distinguished by long experience in war, the other by his noble birth. They were accompanied by Hippias, the expelled tyrant of Athens, who had hoped, from the sympathy and ambition of the Persian monarch, to obtain what he could not expect from the consent of his fellow-citizens, or the interference of the other states. The armament sailed first to Eubœa, took and plundered Eretria, and from thence prepared to pass over into Attica.

The Athenians, while so great a storm was impending, were not inattentive to the means of security. Besides collecting all their own military force, they applied for aid to the other states of Greece, and particularly to the Lacedæmonians. That slow and cautious people, either from superstition or timidity, declared that their religion rendered it unlawful for them to dispatch an army before the time of full moon. The other states were still more backward. The Platæans alone, who lay under peculiar obligations to the Athenians, joined them with 1000 men.

Miltiades was at this time the most eminent man in Athens. He was sprung from one of the most distinguished families in the city. Having conducted a colony to the Chersonese, where he reigned with almost absolute power, he had an opportunity, when Darius led his expedition against the Scythians, of observing the materials and disposition of the Persian armies. The Athenian system of military command seems then to have been singularly cumbersome and inconvenient. Ten generals were appointed, who commanded in rotation, each for a single day; while one of the archons, named the Polemarch, had the supreme decision in all doubtful questions. Miltiades, however, in this crisis of public danger, was raised by his own talents, and the wisdom of his colleagues, to the chief direction of affairs. Some urged the propriety of a protracted, and merely defensive system of warfare, until the torrent should have spent its force, and the strength of Greece had time to be collected. But Miltiades, addressing himself to Callimachus, who was then Polemarch, after representing the transcendent importance of this decision, which would either obliterate the name of Athens, or raise her to the first rank among Grecian states, gave his opinion decidedly in favour of an immediate engagement. The whole Athenian people were now ardent and united in this glorious cause; but a delay might breed divisions, and cause this spirit to evaporate. Room would be left for Persian influence and Persian gold, the fatal effects of which had been recently experienced in the fall of Eretria. Callimachus, satisfied with these arguments, acceded to the advice of Miltiades. Aristides, who was one of the ten generals, gave, on this occasion, the first example of that virtuous disinterestedness which marked his character, by resigning, on his day, the command to Miltiades. This example was followed by the rest. Miltiades, however, with a prudent moderation, declined fighting till his own day arrived. He drew up his army in a manner which enabled him to call forth all its energies, while it rendered unavailing those of the enemy. The strength of the latter consisted in cavalry and bowmen; accustomed to fight at a distance, and to advance

and retreat alternately, over the vast plains of Asia. The force of the Grecian armies, on the contrary, consisted almost entirely in their heavy infantry, armed with pikes, and ranged in a deep phalanx. Miltiades, who knew the strength and valour of this body, was satisfied, that when it came to close combat, nothing in the Persian army could resist its charge. To diminish the effect of superior numbers, he chose a spot which was confined on one side by a mountain, and on the other by a morass. He placed his heavy armed foot, in which all his confidence rested, (though, including the Plateans, it amounted only to 10,000 men.) on each of the wings, leaving the centre to be occupied by light armed troops, and even by slaves, a number of whom had been armed on this emergency. These were more numerous, but from their inferiority in discipline, Miltiades fully calculated on their giving way in the first instance. The Persians, on the other hand, ranged their cavalry and light troops in the wings, and placed in the centre the forces of Persia Proper, which alone were fitted to engage in close combat. Miltiades, in order to encumber the movements of the enemy's cavalry, had caused trees to be felled, and laid across the field. The Persian wings, however, advancing as well as these obstacles would permit, poured upon the Greeks a shower of missile weapons of every description. The Athenians, agreeably to the order of Miltiades, did not return a single javelin, but raising a shout, pressed forward in the most rapid manner upon the ranks of the enemy. A mode of attack so unusual, excited at first surprise and derision; but these were soon changed into terror, when they felt the charge of this formidable body, which their cavalry in vain attempted to penetrate. Every thing gave way before the weight of the Athenian phalanx, and in a short time both wings of the enemy were routed, and fled in confusion. Miltiades, then, recalling his victorious wings from the pursuit, attacked in flank and rear the Persian centre, which, having defeated the troops opposed to it, was following them precipitately. The most arduous part of the contest now ensued; for this was the body whose firmness had dissipated all the other armies of Asia. Its situation, however, and the superior valour of the Greeks, soon decided the conflict. The Persians, routed, sought refuge in their ships, whither they were pursued by the victorious Greeks. As an instance of the eagerness with which the latter followed, it is related, that one, having laid hold of a boat with his hand, when that was cut off, seized it with his teeth. The Athenians, in this engagement, lost only 200 citizens, with two of their generals, one of whom was Callimachus the polemarch. The Persians left upwards of 6000 on the field of battle, besides losing an immense booty, and several of their ships. They then made an attempt, by doubling the promontory of Sunium, to take Athens by surprise. But Miltiades, by a rapid march, arrived in time to render this attempt fruitless. The Persian commander then sailed back to the coast of Asia.

Such was this battle, for ever memorable by an issue so contrary to all appearances, and so auspicious to the happiness and freedom of mankind. A small city, hardly numbered till now among the states of Greece, had baffled and driven back in confusion the collected might of the ruler of Asia. Athens had now begun her career of glory; and a series of triumphs succeeded, which soon raised her to be the first among the Grecian states.

The popular favour, however, which attended the

general who had led them to victory, was not of long duration. Such a pre-eminence, enjoyed by any one citizen, was thought dangerous to the liberty of all; and Miltiades having, in the Chersonese, possessed the power, and even the title of tyrant, was supposed likely to aim at a similar pre-eminence in Athens. We hear of no behaviour of his own which could give countenance to those rumours; but their circulation gradually predisposed men's minds unfavourably towards him. This soon appeared, when a disaster befel him. Being sent with a fleet to chastise the islands which had submitted to, and assisted the Persians, he performed his commission at first with success, and exacted large sums from them. But on coming to Paros, he was prompted by private resentment against Tisagoras, a leading man in the island, to make so enormous a demand, as determined the inhabitants to resist to the last extremity. He was wounded in the siege; but at the end of 76 days, the place was on the point of falling, when Miltiades, discovering a light on the shore of the opposite continent, hastily mistook it for the approach of a Persian armament, raised the siege, and returned to Athens. An unfortunate man was never welcome there. An accusation was soon preferred against him by Xantippus, the father of Pericles; he was condemned to pay 50 talents; and not being possessed of that sum, was thrown into prison, where he soon after died of his wounds.

Such was the unworthy fate of the most illustrious of Athenian commanders. Yet so fruitful was she then in great men, that scarcely had he disappeared, when two arose, who were well worthy of supplying his place. These were the celebrated rivals Themistocles and Aristides. No greater contrast could be exhibited, than by the character of these two men. The former seems to have possessed every quality which could enable him to take the lead among the multitude. Bold, impetuous, enterprising even to rashness, and at the same time artful, subtle, versatile, he at once possessed a conformity of character which made him the object of their favour, and could practise every art for availing himself of that favour; nor was he restrained by any very scrupulous rules of morality, from using such means as seemed most likely to accomplish his ends. He promoted, however, to the utmost, the greatness of his country, whether out of patriotism, or at least as connected with his own greatness. While he favoured the cause of the people, Aristides, on the other hand, supported that of the aristocracy. This man was in every respect the reverse of Themistocles. Moderate, rigidly and immovably just, little ambitious of popularity, he rested satisfied with the approbation of his own mind, and stooped to none of those arts by which his rival conciliated the public affection. The party, besides, to which Themistocles had attached himself, was now become decidedly superior. After a severe struggle, therefore, he found means to effect the banishment of his rival, which was decreed by means of the *ostracism*, an institution peculiar to Athens, and of a very remarkable nature. By it, any citizen, without accusation or trial, by the mere votes of the people, (written on a species of shell,) might be banished for ten years. It inflicted no stigma, being generally imposed on the most eminent citizens, from whom it was supposed that most was to be feared. Some have branded it as an absurd and capricious exercise of popular despotism; while others applaud it as a mild and effectual method of preventing that tyranny, which, in a popular state, is apt to ensue

from the too commanding character of any one individual. Something between the two may probably be the soundest opinion; for though, in such a constitution as that of Athens, there seems a real ground for the institution, yet there is no doubt that it was often capricious and unjustly exercised.

Themistocles was now left supreme head of the republic. In this capacity he performed a signal service to his country, and to all Greece. The war with Ægina reviving, made the Athenians continually sensible of their naval deficiency. Impressed with this, Themistocles found means to persuade them, that the money produced by the silver mines, which had hitherto been spent in feasting and entertaining the people, should be employed in constructing a fleet. A hundred galleys were accordingly put upon the stocks; and with such ability were the funds managed, that Athens soon became the first maritime power in Greece. This became the safety, both of herself and of all the other states, in the mighty storm which was now impending.

Darius, after the disastrous result of his expedition to Greece, was withheld from farther attempts by an insurrection in Egypt, as well as by domestic dissension. About five years after, however, he died, and was succeeded by Xerxes, a rash and ambitious young prince, who, persuaded by his flatterers that nothing was impossible to the master of such an empire, determined to collect all his forces for this arduous enterprise. Darius had been three years occupied in preparations, which Xerxes devoted four to complete. All the ports of the Asiatic colonies, as well as of Egypt and Phœnicia, were employed in the construction of an innumerable multitude of vessels, surpassing in magnitude any that had yet appeared in those seas. Twelve hundred ships of war, and three thousand of burden, were at length completed. All the subjects and vassals of Persia were called upon to furnish their quotas of troops, and an armament was thus collected, to which the world has seen nothing equal, either before or since. Herodotus has given an elaborate enumeration, which makes them amount to upwards of two millions, besides women and eunuchs; which, added to five hundred thousand who manned the fleet, raises the whole number employed to nearly three millions. Wishing to avoid the unfortunate example of Darius, as well as the inconveniences of a long navigation with so many troops on board, he determined to transport his army over the Hellespont. After some difficulty, a bridge of boats was extended from one side to the other, over which the army continued passing for seven days and seven nights without interruption, until the whole arrived on the Thracian Territory. Then separating into three divisions, they advanced, covering the plains of Thrace, Macedonia, and Thessaly. Most of the inhabitants of these countries, overawed by this immense force, joined their standard. After a memorable encounter, they penetrated through the pass of Thermopylæ, and being joined by the Thebans, poured down with their whole force upon Attica and Peloponnesus. The Peloponnesian states, conceiving themselves unequal to cope in the open field with so mighty a force, determined to withdraw within the Peninsula, and to fortify the isthmus of Corinth. The consequence of this arrangement was to leave exposed the territory of Attica. Themistocles then saw, that the land force of that state alone could never cope with the whole power of the Persians, seconded, as it was, by a strong body of Grecian auxilia-

ries. Instantly, therefore, with equal wisdom and decision, he formed his plan, which was to abandon the city, and embark on board the fleet all the hopes and fortunes of Athens. To persuade the people, however, to the adoption of such a measure, was no easy task. No where, perhaps, was local attachment so strongly rooted as among the Grecian states. It was interwoven with all the feelings of religion, of patriotism, and of parental veneration. To abandon to a barbarous foe, their city, the temples of their gods, the tombs of their ancestors, appeared absolute profanation. Themistocles, on this occasion, exerted all his address. He represented to his countrymen the necessity and advantage of this measure; but his chief dependence was on a dexterous management of that superstition, which at present formed a powerful obstacle to his scheme. He contrived to get an oracle from Delphi, which advised them to *defend themselves with wooden walls*; which he interpreted to be their ships. He procured from the same quarter a high panegyric on Salamis, where he wished the fleet to station itself. He accompanied the evacuation of the city with a variety of ceremonies, which gave it the appearance of a religious act. The women and children were sent to Troezen, which generously received them, although Argos, to whose territory it belonged, had basely espoused the Persian interest. When the time of departure, however, arrived, the scene which ensued was affecting beyond expression. Besides separating from all those objects and places, which from infancy they had been accustomed to regard with affection, they were obliged to leave behind a number of old citizens, whom they had not time to remove. Some emotions of tenderness were even inspired by those domestic animals, who, by dismal howlings, expressed their affection and regret for their departing masters.

We have now to look back to the operations of the two fleets. Xerxes, recollecting the disaster which that of Darius had sustained, in doubling the promontory of Mount Athos, determined to cut a canal through the neck of the peninsula, sufficient to allow two galleys to sail abreast. The fleet passing through this canal, followed the army along the coasts of Greece, till it arrived and anchored in the bay of Sepias. No harbour could contain so immense an armament, it was therefore necessary to station itself in the road, which extends from the city of Castanea to the promontory of Sepias. The Grecians meanwhile had stationed theirs at Artemisium, the northern promontory of Eubœa. The Lacedæmonians still retained such a pre-eminence among the other states, as procured for their admiral the command of the whole fleet, although of 380 triremes, they sent only ten.

The Athenians, who had already sent 120, and were preparing more, were disposed to murmur; but Themistocles, with consummate prudence, prevailed on them to acquiesce, rather than cause dissension at so critical a period. Most of the Peloponnesian states urged the necessity of an immediate retreat, in order to assume a station, where they might defend their own coasts. This proposal was strenuously opposed by Themistocles, who looked upon it as equally dishonourable and pernicious to Greece. By his arguments, and by threatening that the Athenians would withdraw, and found a colony elsewhere, he prevailed on the allies to relinquish this design. Meanwhile the Persians, unable to find secure anchorage for their immense fleet, had suffered ex-

trremely from a violent storm. Before they had recovered from this disaster, the Greeks made a nocturnal attack, took thirty of their vessels, and destroyed as many more. Next day they again attacked them, and cut off the Cilician squadron. The same storm which had shattered the grand Persian fleet, completely destroyed a division of them which had sailed round Eubœa, in order to take the Greeks in the rear. These favourable circumstances animated the hopes of the confederates, and dispelled in some measure, the terror which had been inspired by the power and numbers of the enemy. When, therefore, on the third day, the Persians advanced and offered battle, it was not declined. The combat was more obstinate and bloody than any of the preceding. At length, however, the Persians retiring, resigned their claim to the honours of victory. The Greeks, however, had suffered so much, that it appeared impossible to fight such another battle. It was at last determined to retire, and station themselves in the Saronic Gulf, between Athens and Salamis.

Meantime Xerxes, with the flower of his army, advanced in person into Attica, and proceeded to Athens. That city was still occupied by a few, who could not be removed, or who had preferred remaining. These, abandoning the town, endeavoured to defend themselves in the citadel. They were for some time successful; the strength of the situation, and their own superior valour, rendering the attempts of the enemy fruitless. At length, however, a path was discovered, on a side of the edifice, supposed inaccessible, and therefore left unguarded. By this the Persians ascended, and having put all to the sword, set fire to the citadel, as well as to the temple of Minerva, which was its chief ornament. So elated was Xerxes with this easy conquest, that he immediately sent an express to announce it to Artabanus, at Susa.

When the confederate fleet, from their station at Salamis, beheld the disaster of Athens, they were struck with the deepest alarm. Eurybiades, their Spartan admiral, in conformity with the general sentiment, resolved to retire to the isthmus, with the view of covering the coast of Peloponnesus. Themistocles, however, to whom such a step appeared altogether ruinous, and also instigated by an Athenian, called Menesiphilus, went immediately to Eurybiades, and represented, that if the Peloponnesians were once brought to their own coast, no power could prevent them from leaving the fleet, and returning to their homes; that all the hopes of Greece rested in her fleet; that therefore if this measure was adopted, Greece was lost. Eurybiades was little disposed to listen; and, offended with the warmth of Themistocles, lifted up his cane; to which the other replied in the memorable words: "Strike, but hear." Eurybiades heard, and at length agreed to call a council of the fleet. Here Themistocles prudently avoided the argument which he had urged most strongly to Eurybiades, but which was now likely to prove offensive. He represented the advantages of fighting in a narrow sea, where the enemy could not avail themselves of their numbers, and where, therefore, the superior valour of the Greeks, and strength of their vessels, might be expected to prevail. He even threatened, that the Athenians would desert allies who paid so little regard to their interest, and would found a colony in Italy. This last argument proved the most powerful of all, as the Athenian vessels formed the strength of the fleet. The dispute, however, was

warm; and even personal sarcasms were thrown out upon Themistocles, to which, however, he replied so skillfully, as made them recoil on his adversaries. It was at length determined to stay. But when shortly after the Persian fleet began to approach, and the sea appeared covered with innumerable vessels, their courage again wavered, and a general disposition prevailed to set sail, without delay, for the isthmus. Themistocles, ever fertile in expedients, adopted on this occasion a most singular one. By means of a Persian captive, whom he had with him, he sent a message to Xerxes, expressing his attachment to that monarch, and informing him of the intended retreat of the Greeks. He advised him, therefore, to send two hundred vessels round the islands of Ægina and Salamis, which, placing themselves in the rear of the confederates, might prevent the meditated escape. To a monarch so confident of his own power, the advice appeared plausible, and it was therefore adopted without hesitation. Next night, therefore, when the Grecians were deliberating on retreat, news arrived that it was no longer practicable; that they were completely surrounded. This intelligence was confirmed by a most respectable authority. Themistocles, forgetting in this emergency his private resentments, had persuaded the Athenians to recall his rival Aristides; and that distinguished patriot having made his way through the Persian fleet, arrived while the council was yet sitting. The intelligence he brought was confirmed by others; so that the Greeks now saw that they had no alternative but to prepare for immediate battle.

The Athenians were stationed on the left wing, nearest to the coast of Attica, and were opposed to the Phœnicians, the first naval power under the dominion of Persia. The Peloponnesians, on the right of the Greeks, were opposed to the Ionians, and other Asiatic Greeks, who occupied the left of the Persians. Themistocles judiciously delayed the attack till the hour when a customary breeze sprung up from behind, under favour of which he bore down upon the Persians. Although he was not the nominal commander, yet the universal opinion of his skill made his example the rule to every one. The Grecian fleet amounted to three hundred and eighty vessels, while that of the Persians exceeded twelve hundred. In consequence of the confined situation, however, in which the battle took place, the latter could not bring a much greater number into the action, but were obliged to arrange their vessels in successive lines, one behind the other. The first and severest shock was on the right, between the Athenians and Phœnicians. But besides the glorious motives by which the former were animated, they acted in an orderly manner, and on a regular plan; while their adversaries fought blindly, and without concert. Victory therefore soon declared on their side. On the other wing, where the Asiatic Greeks fought for Xerxes, it was still sooner decided. These nations, remembering their origin and ancient liberty, were little ambitious of imposing on kindred tribes the same servitude under which they themselves groaned. They soon either deserted or fled. The whole of the first line thus discomfited, fell back on those behind, among whom they spread dismay and disorder. There were no means of rallying such a confused multitude; in a short time the whole fleet took to flight, and the victory of the Grecians was complete. A body of select Persian infantry which had thrown themselves on the

rock of Psyttaleia, to cut off such of their enemies as might seek shelter there, were themselves surrounded and cut to pieces.

Thus terminated this battle, so memorable in the annals of Greece and of mankind. Xerxes, from the shore, where he had seated himself, beheld this mighty disaster, which levelled his towering hopes in the dust. Themistocles at first entertained a plan of detaching a squadron to occupy the Hellespont, and prevent the return of the Persians. But Aristides prudently observed, that their object was far less to destroy this armament, than finally to rid Greece of it; and that it was dangerous to reduce such a host to despair. Themistocles then adopting an opposite policy, sent by his former channel an intimation to Xerxes, that such a design was entertained by the Greeks, exhorting him to lose no time in effecting his retreat. Xerxes, in whom the impression of fear was then as predominant as that of false confidence had before been, made no hesitation in taking the advice; and, with the great mass of his army, made a tumultuous retreat to the Hellespont. He left Mardonius, however, with three hundred thousand men; a number which included perhaps all the real strength of that formidable army, freed from its useless incumbrances.

The Athenians had now returned to their city; and Mardonius hoping to gain them over by the dread of a second time losing it, sent Alexander, king of Macedonia, to urge them to submit. The Athenians firmly rejected his proposal; but this magnanimity did not meet with its proper return on the part of the Peloponnesians. They again resolved to confine themselves to the defence of their own peninsula, by drawing a wall across the isthmus. The consequence was, that Athens was a second time taken and plundered. The remonstrances of the Athenians, however, and perhaps the dread of their desertion, at length recalled Sparta to more honorable sentiments. She collected her own force and that of her allies, marched it beyond the isthmus, and joined the Athenians. The combined armies, next summer, fought the battle of Plataea, in which, though the Lacedæmonians took the leading part, yet the services of Athens were considerable. She engaged those Greeks, a numerous body, who, to the shame of their country, fought on the side of its enemies. The signal services they had rendered to the common cause, secured them the command of the left wing, which had before been uniformly conferred on the Tegeans.

The Athenians distinguished themselves still more in an action which was fought on the same day, near the promontory of Mycale, in Ionia. The wrecks of the Persian fleet having taken refuge on the coasts of Asia Minor, the Greeks followed them. Under these circumstances, the Ionians conceiving this a favorable opportunity for throwing off the Persian yoke, applied to them for aid. They did not decline the invitation, but landed, and joining their forces to those of the Ionians, gave battle to the Persians, who had assembled an army vastly superior. After an obstinate combat, the Persians were completely routed. The Spartans pursued those who fled towards the passes of the mountains, while the Athenians stormed their camp. In consequence of this victory, Ionia was freed, and a large portion of the Asiatic coast rescued from the hands of the enemy.

The Athenians followed up their victory, by besieging Sestos, a large town of Thrace, commanding the straits of the Hellespont, which they took after a long siege.

The first care of the Athenians, after returning to their city, was to rebuild their walls, and to give them additional strength and solidity. This measure was opposed by the Lacedæmonians, under pretence of its being contrary to the interest of Greece that there should be strong places beyond the isthmus. Their real motive, however, was suspected to be an aversion to the rising greatness of the Athenians. Themistocles conducted himself here with great art. He got himself appointed ambassador to Sparta; and before setting out, he caused all the citizens, of every age and sex, to apply themselves to the task of building the walls, making use of any materials which were within their reach. Fragments of houses, temples, and other buildings, were accordingly employed, producing a grotesque appearance, which remained to the days of Plutarch. He then set out for Sparta, but on various pretences declined entering on his commission, till he had received intelligence that the work which he had set on foot was nearly completed. He then went boldly to the Lacedæmonian senate, declared what had been done, and justified it not only by the natural right of the Athenians to provide for their own defence, but by the advantage of opposing such an obstacle to the progress of the barbarians. The Lacedæmonians, sensible of the justice of this argument, and seeing that remonstrance would now avail nothing, were fain to acquiesce.

Themistocles, ever studious of the maritime greatness of Athens, caused a new and more commodious harbour to be built at Piræus, which in process of time was joined to the city by a very thick wall, five miles in length.

The confederate fleets continued to pursue their advantages. They scoured the shores of Asia Minor, and the Ægean, drove out the Persian garrisons, and enriched themselves by plunder. They also, after an obstinate defence, stormed and took Byzantium.

The Lacedæmonians had hitherto, by common consent, held the chief command, both by land and sea. The recent events, however, had thrown a lustre around Athens, of which no other state could now boast. They had reaped the chief glory both in the battles of Marathon and Salamis; they had suffered most; had always stood forward generously in the common cause; while Sparta had too often observed a cold and selfish policy. These favorable impressions were heightened by the contrast of the consummate justice and good conduct of her commanders, Aristides and Cimon, with the haughtiness and insolence of Pausanias the Spartan king. Moved by these different considerations, the allies unanimously determined to transfer the chief command at sea, now much more important than land, to the Athenians. The Lacedæmonians wisely forbore an opposition, which they knew would be vain: and as a common treasury was necessary for the prosecution of a naval war, Aristides, in whom entire confidence was placed, was chosen both to fix the quotas of the different states, and to perform the office of treasurer. The allies did not ultimately find much reason to congratulate themselves on this new arrangement.

The period, of nearly fifty years, which elapsed from the end of the Persian to the commencement of the Peloponnesian war, is the most splendid in the history of Athens. During this period, she held an undisputed pre-eminence among the states of Greece; yet there occur not, in the events by which it was distinguished, any which were peculiarly remarkable by their magnitude or importance. To prevent the confusion of rela-

ting a number of detached incidents, we shall divide them into three parts: Her internal affairs; her maritime operations; and her operations by land.

The rivalry of Themistocles and Aristides continued; but though the latter held now a prominent character in the eyes of Greece, Themistocles was still the most powerful at home. The power of the people, which had long been preponderant in Athens, was greatly strengthened by the issue of the Persian war. All offices were now laid open to them. It was only by gaining their favour, that any chief could rise to the head of the republic. All therefore vied with each other in flattering them, and in removing every remaining obstacle to their uncontrolled sway. Themistocles continued to administer public affairs with vigour, attending particularly to the improvement of the navy. In time, however, envy and jealousy, with the rising influence of competitors, particularly of Cimon, sapped the foundations of his authority. This soon appeared, when the Lacedæmonians, always his enemies, preferred an accusation against him, as privy to the treason of Pausanias. It appeared indeed that he had known of it, but he strenuously denied having given his concurrence. He was banished, however, by the ostracism; was driven, by the combined power of both states, from city to city; and at length forced to take refuge in Persia, where he died.

Aristides died about the same time, universally lamented, (See ARISTIDES.) The whole power then came into the hands of Cimon the son of Miltiades, one of the most illustrious and accomplished characters whom Greece ever produced. He seems to have combined the justice of Aristides with the enterprize of Themistocles. He rather inclined to favour the aristocratical party, which always connected itself with Lacedæmon, insomuch that he acquired the surname of *Philolacones*. Necessity, however, as well as generosity, prompted him to the most profuse distribution of the wealth which he obtained by his conquests in Thrace and Asia Minor. He kept an open table; he allowed indiscriminate admission to his farms and gardens. In process of time, however, he shared the usual lot of the chiefs of Athens. His aristocratical propensities were not welcome to the people, who were now all powerful; and his regard to national justice often clashed with that eagerness to grasp at every mode of acquisition, which too much distinguished the foreign policy of Athens. He was accordingly accused for not having, without the least ground, made war on Macedonia, and he was condemned by the ostracism.

His successor was Pericles. He had supplanted his rival by the sedulous practices of all those arts, by which popular favour may be attained. The measures, however, which he proposed for this purpose, were far from being either laudable or beneficial to Athens. They consisted in removing every remaining check on the power of the people, already too exorbitant. He contracted greatly the jurisdiction of the Areopagus, which had probably given umbrage to the popular assembly. Still, however, they missed the splendid liberality of Cimon, which Pericles was unable to rival. Out of this dilemma, he extricated himself in a manner equally unjustifiable and pernicious. He persuaded the people to employ, in their private accommodation and amusement, not only the public money, but the common treasury of Greece. It must be owned, however, to have been spent, under his direction, with

equal taste and magnificence. He adorned the city with splendid works of art; he encouraged learned men; and the drama, under his auspices, rose to a perfection before unattained. His management of the foreign affairs of the republic, was moderate, wise, and vigorous. Cimon, after five years of banishment, was recalled, but died soon after, leaving the field entirely open to his successor.

While these changes were going on at home, Athens carried on a continued and successful war against Persia, and all those who adhered to her cause. The fine island of Cyprus was first rescued from them; after which Cimon was sent to expel them completely from Thrace, an undertaking which was facilitated by the capture of Byzantium. Eion and Amphipolis, the only towns now remaining to them, were reduced, though the latter made a dreadful resistance; and when all hopes were over, the inhabitants threw themselves, with their wives and children, into the flames, rather than submit.

Cimon, having thus cleared Europe of the common enemy, sailed into Asia Minor, where, with the aid of the Grecian inhabitants, he drove them completely out of Caria and Lycia. He was then proceeding to attack Pamphylia, but Artaxerxes, solicitous to preserve his provinces, had fitted out a formidable army and fleet. The former encamped on the banks of the Eurymedon; the latter, of 400 sail, was at the mouth of the river. Cimon immediately sailed with 250 galleys, attacked the Persian fleet, sunk a great part of it, and captured the rest, which had vainly sought shelter in the island of Cyprus. About 20,000 troops were found on board, which suggested to Cimon the following stratagem. He dressed his men in the clothes of these Persians, and hastening to the Eurymedon before the news of his victory had reached the Persian camp, procured admittance into it, attacked the army unexpectedly, totally defeated it, and made the greater part prisoners. These two victories, which were gained on the same day, raised Cimon to the utmost height of glory. An immense booty fell into the hands of the conquerors.

Soon after, an arrangement took place, which completely rivetted the maritime supremacy of Athens. All these enterprises had been carried on by the confederate fleet of Greece, under Athenian commanders. But the allies grew weary of furnishing ships and men; and Athens gladly consented to take this upon herself, on condition of their paying a composition in money. The sum was at first moderate; but Athens, now enjoying the whole maritime power of Greece, raised it at her will.

The Egyptians having revolted against the king of Persia, the Athenians, always ready for any adventure, undertook to aid them. The army which they sent was at first successful, defeated the Persian forces, and laid siege to Memphis. When they were worn down, however, by the fatigue of this siege, a new army, commanded by Megabazus, advanced upon them, compelled them to raise it, and to evacuate Egypt. The greater part perished in their retreat through the Lybian desert. Part of their fleet also was surrounded, and cut off by the Phœnicians.

These disasters deterred the Athenians, for seven years, from any farther enterprises. On the recall of Cimon, however, he was sent with a fleet to Cyprus, which had been recovered by the Persians. He was

proceeding to execute this commission with his usual success, when he received, at the siege of Citium, a wound, of which he died.

Artaxerxes, at length, foreseeing nothing but disaster from the prosecution of an Athenian war, made proposals of peace. Athens obtained the most honourable conditions: the independence of the Grecian colonies in Asia Minor, and the exclusion of all Persian ships from the Grecian seas. Such was the glorious termination of a war, which had lasted, with little interval, for upwards of fifty years.

While Greece was thus triumphing over the common enemy, the flame of discord began to rage in her own bosom. Sparta beheld, with a jealous eye, a power formerly so inferior, carrying off all the prizes of glory and ambition. She had been thwarted besides in two measures supported by her after the retreat of Xerxes; one, that all those states which had assisted the Persians, should be excluded from the common council of Greece; and the other, that the Ionians should be transported into Europe, where they would be secure from Persian resentment. Justice seemed to sanction the one measure, and generosity the other. Both, however, were successfully opposed by Themistocles; who conceived that the first would give Sparta too great a preponderance, and that the last would raise up a powerful commercial rival to Athens. These discontents silently fermenting, would probably have broken out sooner, had not Sparta been occupied at home by a dreadful insurrection of her slaves. The Athenians generously sent troops to her aid, and were highly offended when they found that these had been dismissed, while the troops of the other allies were retained. They took a most extraordinary method of revenging this slight. The Lacedæmonians having undertaken an expedition into Phocis, Athens sent a body of troops to the isthmus to cut off their retreat. The Lacedæmonians then marched into Bœotia, and threatened Attica.

An army being brought to oppose them, a battle was fought at Tanagra, in which the Athenians were defeated. In consequence of this success, the Thebans were encouraged to apply to Sparta for aid against the smaller towns of Bœotia, which had thrown off their authority, and were protected by Athens. The Spartans accordingly sent a powerful army to their support; but the Athenians, under the conduct of Myronides, an active and able officer, attacked the confederates, though greatly superior in number, and gained a complete victory, which placed all Bœotia at their disposal.

The Athenians, some time after, had another difference with the Lacedæmonians, on the subject of Megara. Plistonax, king of Sparta, marched with an army into Attica; but Pericles, by a bribe of ten talents, persuaded him to return. Pericles, in accounting for this sum to the people, is said to have stated it as "laid out in a fit manner on a proper occasion:" the first notice we find in history of *secret-service* money.

About this time the Athenians being applied to for assistance by the Sybarites against the Crotonians, sent an expedition, which restored the former to their city.

Megara was not the only city which threw off the yoke of Athens; a number of the maritime states, who groaned under her exactions, endeavoured to retrieve the fatal error they had committed, of commuting naval service for money. Pericles, however, with a fleet and army, sailing to each successively, reduced them; and

rendered their bondage still heavier than before. He particularly distinguished himself in the expeditions to Eubœa and Samos.

The train of dissension, however, was now laid on the Grecian continent, and required only a spark to produce a mighty conflagration. That spark was not wanting. A quarrel arising between the Corinthians and Coreyreans, both sides sent ambassadors to request assistance from Athens. An assembly of the people being called, and having heard the arguments of both parties, decided at first in favour of the Corinthians, but afterwards, with characteristic levity, changed to the side of the Coreyreans, whose alliance, as a naval power, appeared likely to be more useful. A squadron was accordingly sent to the aid of the latter people, and assisted them in an obstinate engagement which they maintained against their adversaries. The Corinthians, anxious to find out other employment for the Athenian arms, contrived to excite a rebellion in Chalcidicæ, one of their finest dependencies, bordering on Thrace and Macedonia. The Potidæans, who took the lead in this affair, being attacked by an Athenian fleet and army, received from Corinth an aid of 2000 men, who threw themselves into their city; notwithstanding which, after an obstinate defence, they were reduced to extremity.

The Corinthians, finding themselves thus deeply involved with so formidable an adversary, saw no resource but in the great rival of Athens. They sent ambassadors to Sparta, representing the imminent danger to which that state exposed itself and all Greece, by suffering the Athenians to make such rapid advances in dominion. After an obstinate debate, the Spartans determined to espouse their cause, which was then quickly joined by many other states, who envied or dreaded the prosperity of Athens. A joint embassy was sent to that city, demanding the liberty of all those Grecian states which she now held in subjection. Other demands were added, which appeared to be still more inadmissible. Pericles advised and procured their rejection. War, however, with so powerful a confederacy, was by no means popular; and the enemies of Pericles laid hold of this opportunity to attack him. Several of his friends were tried and banished; and an accusation was brought forward against himself, for having embezzled the public money. From this charge, however, he cleared himself in such a complete and satisfactory manner, as silenced his accusers, and regained him the popular favour.

Meanwhile the Peloponnesian war began by an unsuccessful attempt of the Thebans to surprise Plataea. This war possessed characters which distinguished it from almost every other, and which more than doubled the usual calamities of arms. It was as much a civil as a foreign war; for in every city there was a party, and commonly a numerous party, entirely devoted to the enemy. This arose from the difference in form of government between Sparta and Athens; the one inclining strongly to aristocracy, while the other was entirely popular. Each of the two nations, on becoming masters of any city, established in power that party which favoured their own form of government, while the heads of the opposite faction were proscribed or banished. These last again, when a counter revolution took place, had not only their security to provide for, but their vengeance to gratify. Thus boundless scope was given to ambition, party rage, the thirst of revenge; the Grecian character, according to Thucydides, underwent an entire change; all the ties of nature were trampled upon; and Greece

exhibited, during thirty years, a perpetual scene of conflict and calamity.

Almost all Greece took part in this quarrel. Most of the continental states sided with Sparta, which was most powerful by land; Argos, however, with its dependencies, stood neuter, while the Acarnanians, who bordered on Corcyra, and Plataea, an ancient ally, espoused the Athenian interest. The Athenians again were assisted, rather through fear than affection, by all the maritime states, comprising the islands and the coast of Asia Minor. Chios, Lesbos, and Corcyra, furnished vessels; the rest, money and men.

The Lacedæmonians determined, without delay, to avail themselves of their superiority on land, by marching, with their whole forces, into Attica. The Athenians, who had no army which could face them in the field, adopted, by the advice of Pericles, a system of warfare entirely defensive. They withdrew from the country, and leaving it as completely a desert as possible, transported their whole population within the walls of Athens. The confederates arrived, spread themselves over the fields, burnt houses and villages, and attempted, by every insult, to excite the Athenians to leave the city and give them battle. Pericles, however, though with the utmost difficulty, succeeded in retaining them within their walls. Meanwhile he sent a powerful fleet, with troops on board, to ravage the coasts of Peloponnesus. This circumstance, joined to difficulty of subsistence, at length induced the confederate army to withdraw.

Next summer, Attica was exposed to a similar invasion, and the same measures were taken. This year, however, was rendered much more calamitous, by a dreadful plague which broke out in Athens, and swept away multitudes. Among its victims was Pericles, at a time when his services were most wanted.

A new disaster was soon added to those with which Athens was already afflicted. Lesbos, one of the most powerful among its subject-allies, revolted. It had been allowed to retain a greater measure of liberty than the others; but still the yoke was so heavy, that it availed itself of the first opportunity of shaking it off. Buoyed up by promises of aid from the Peloponnesian confederacy, the Lesbians set the power of Athens at defiance. The Athenians, though at first slow to believe this defection, yet when they could no longer doubt its truth, they made every exertion against their new enemy. They fitted out a powerful armament, which they entrusted to Paches, an able officer. Being assisted by the neighbouring islands, and meeting with no very powerful resistance, they were soon able to blockade Mitylene, the capital of that island. The Lacedæmonians, meanwhile, were actively employed in equipping a fleet for its relief. Their operations, however, proceeded with characteristic slowness: and when it was at last fitted out, they entrusted the command to a very ill qualified officer. In consequence of his feeble and dilatory measures, the Mitylencans were obliged, before assistance arrived, to surrender, on the hard condition of their lives being spared only till they should have an opportunity of imploring the mercy of Athens. Their confidence in it, however, was by no means well founded; for on the matter being laid before the people, they immediately passed the inhuman decree, by which all the Mitylencans, fit to bear arms, were to be put to death, and the women and children sold to slavery. Happily, however, this stain on the Athenian

name was in some measure obliterated. Next day there was a general relenting, of which the Mitylenean deputies availed themselves to procure the calling of another assembly. This shameful decree, though by too small a majority, was then repealed, and the punishment of death inflicted only on a certain number, who were peculiarly guilty.

During this time, the most horrible dissensions were raging in Corecra, which terminated in a bloody triumph of the party devoted to Athens. The Athenians then conceived the hope, that, by the aid of the Acarnanians, of a party of revolted Messenians, who had taken refuge at Naupactus, and of the neighbouring islands of Cephallenia and Zacynthus, they might succeed in reducing all Ætolia to subjection. They accordingly overran great part of the country, and even stormed the capital Ægittium; but the Ætolians, carrying on a desultory warfare, harassed them to such a degree, that they were obliged to renounce the enterprize, and return, in a very shattered state, to Naupactus. The enemy, however, having in their return ventured to attack, were repulsed and defeated with great loss; which saved the reputation of Demosthenes, who commanded the armament.

Their attempts to penetrate into the country having thus proved abortive, the Athenians, with their allies, next undertook an expedition to the western coast of Peloponnesus. Passing near Pylus, the Messenians were seized with an ardent desire of again establishing themselves in their native seats. Demosthenes could not, at first, persuade his colleagues to enter into this plan; till, a storm happening to drive them to the very spot, it was in a manner forced upon them. They accordingly began to fortify the place with great activity. The Lacedæmonians hastened to assemble their forces, in order to crush, at once, a scheme so alarming. The attack, however, was unsuccessful: their fleet was defeated, and their army repulsed. These disasters were accompanied by another still more serious, which gave a decisive turn to the state of affairs: To forward their operations against Pylus, they had thrown 400 Spartans into Sphacteria, a small island opposite the harbour. After the overthrow of the fleet, this body of men were entirely cut off from the continent. Inconceivable is the dismay which this event excited in Sparta. The Spartans were so few in number, and yet so completely the vital part of the community, that the loss of this small party became a public calamity of the first magnitude. Their pride was humbled; they sent ambassadors to Athens to sue for peace, and even delivered up sixty ships as a pledge of their sincerity. Athens had now an opportunity of terminating the war with equal glory and advantage: but she had no longer a Pericles to guide her councils; they were chiefly governed by Cleon, a worthless haranguer, who raised himself into favour by flattering the worst passions of his countrymen. At his instigation, they made demands so enormous, as convinced the Lacedæmonians that they had nothing to hope from negotiation. The Athenians even refused, on the most frivolous pretences, to restore the sixty ships, which had been only yielded as a deposit during the negotiation.

Meanwhile the reduction of the island did not proceed so rapidly as was expected. It was strong by nature, and the Spartans defended themselves with obstinacy; so that Demosthenes placed his chief confidence in a blockade, which could not be rendered very strict, from

the proximity of the opposite shore. Cleon, humouring the natural impatience of a popular assembly, indulged in daily declamation against the generals employed. He concluded by declaring, that, with a little valour, nothing could be more easy than to take it without delay. Upon this Nicias proposed to confer the command upon him. Cleon at first pretended to accept it; but, on finding that the people were really disposed to place him in a situation for which he was conscious of being totally unqualified, he endeavoured to draw back. The people, however, amused at the dilemma into which they imagined him to have fallen, would listen to no apology. Cleon was forced to set out. It so happened, that, by the time of his arrival, Demosthenes had reduced the Spartans on the island to the last extremity, so that in a few days they were obliged to surrender; and Cleon, to the surprise of every one, returned in triumph to Athens.

The Athenians now, elated with their good fortune, lost all moderation, and thought only of extending their power in every direction. Nicias took the important island of Cythera, lying at the south-east point of Laconia. Soon after they took Nisæa, the sea-port of Megara, and ravaged the whole coast of Peloponnesus. Fortune, however, soon began to change. A scheme had been formed to invade Bœotia, in concert with the smaller towns of that district, which wished to throw off the dominion of Thebes. The plan, however, was discovered and frustrated; and an Athenian army, advancing to Tanagra, was shamefully defeated. The Bœotians then made themselves masters of Delium.

Meanwhile a still severer storm burst forth on the coast of Macedonia and Thrace. The principal towns in the peninsula of Chalcidice, dreading the resentment of Athens, entered into a league with the Lacedæmonians, and with Perdicas, king of Macedon. The former sent, under Brasidas, a force, small indeed, but rendered formidable by the consummate wisdom of its commander. Brasidas passed the straits of Thermopylæ, which the supine security of the Athenians prevented them from making any attempt to guard. He then advanced into Chalcidice, and, though feebly supported by Macedon, contrived, by the united power of valour and eloquence, to possess himself of Acanthus, Stagira, and most of the cities on that peninsula, not reducing them to subjection, but establishing in power the party favourable to Lacedæmon. He even gained Amphipolis, a most important town, commanding the navigation of the river Strymon, and the access into the interior of Thrace. The Athenians, who were exulting in all the pride of success, were struck with the deepest dismay by the intelligence of these multiplied disasters. Thucydides, the historian, who had commanded on this station, but with a force wholly inadequate, was recalled and banished; and reinforcements were prepared. The Lacedæmonians, however, having prudently taken advantage of this success to solicit an armistice, it was granted, and a negotiation entered into. It was soon broken, however, by the clamours of Cleon, who called upon his countrymen to employ his own experienced talents in retrieving the disasters of the republic. He was dispatched accordingly with a respectable force, which enabled him, in the first instance, to take Menda and Torone. Flushed with success, he ventured on a rash attack upon Amphipolis; but here his army was totally defeated, and himself slain. This calamity was only compensated by the death of Brasidas, who fell in the same engagement.

The Athenians, having suffered this loss, and having no longer Cleon to urge them into violent measures, listened to the voice of reason, and, under the auspices of Nicias, concluded a treaty of peace with the Lacedæmonians. In this treaty it was stipulated, that all the places taken on both sides, in the course of the war, should be mutually restored.

This condition has certainly the appearance of being moderate and reasonable; yet it involved, in fact, an extensive violation of the most solemn engagements. Each party had gained possession of these towns, not as conquerors, but as allies; they had been uniformly welcomed by one party, whose power they had established by crushing the opposite. This party now complained, that, from being the rulers of their country, they were left exposed to all the resentment of the sovereign state from which they had revolted, and, what was more dreadful, to the vengeance of their fellow citizens, whom they had punished or expelled. The cities of the Chalcidice raised loud outcries against Sparta; they refused to yield to a treaty in which they had not been consulted; and general murmurs arose among the allies of both nations. The Corinthians saw in this crisis an opportunity of acting a distinguished part, by espousing the cause of the Chalcidian cities, and of all who thought themselves aggrieved by the treaty in question; and their league was joined by Argos, Mantinea, and Elis.

This confederacy seems evidently to have at first been chiefly formed with the view of resisting the pretensions of Athens; yet such was the restless ambition of that republic, that she soon became one of its leading members. So fair an opportunity of humbling the power of Sparta, it was thought, should not be lost. Nicias, the leader of the aristocratical and pacific party, had prevailed for a time, only through the sudden death of Cleon, the leader of the popular party, which was destined to hold perpetual sway in Athens. The place of the latter was soon supplied by a man of far superior talents; by Alcibiades, the greatest orator, the most accomplished gentlemen, and the first general, of his age; but whose total want of principle rendered these acquisitions, not the safety, but the ruin of himself and of his country. With the view of breaking off the treaty, he is said to have employed an artifice, one of the most shameless that is mentioned in history. Lacedæmonian ambassadors arrived, and, being introduced to the senate, shewed full powers to conclude a treaty, not only of peace, but of alliance for the reduction of the mutinous states. Alcibiades, having invited them to his house, after great professions of zeal in their cause, advised them, in order to negotiate with greater advantage, to conceal the extent of their powers. Next day, in the assembly of the people, he was the first to demand from them the production of full powers; and when they, in conformity to his private advice, denied that they were possessed of such, he immediately burst into a violent invective, contrasted their present declaration with that of the day before, and, accusing them of falsehood and treachery, procured their immediate dismissal.

War was now kindled in Peloponnesus; but the Athenians acted only the part of auxiliaries. Their favourite object was the extension of their maritime dominion. They reduced Scione, a town of Chalcidice, in the peninsula of Pallene, and avenged, with the most atrocious severity, the revolt of the inhabitants. This cruelty, however, proved rather hurtful to their interests. It roused a spirit of resistance, which, joined to the inter-

ference of Perdicias, rendered it impossible for them to make any farther progress in that quarter. They turned next to an enterprise, the most disgraceful and unjustifiable in which they ever engaged. The island of Melos, one of the finest of the Cyclades, had been peopled by a Lacedæmonian colony; yet, notwithstanding its connection with that state, it had, during the whole war, observed the strictest neutrality. The Athenians, however, now sent an armament to take possession of it. They first asked admittance to the assembly of the people: But the Melians, dreading their eloquence, and the contagious character of popular government, chose rather to admit them to an audience of the senate. The conference which took place is preserved by Thucydides, and gives a most curious, but most unfavourable view of the foreign politics of Athens. The only thing like a right which her ambassadors urge, is founded on their having delivered Greece from Persian invasion, whence they infer that they are entitled to command it. Being pressed, however, on this subject, they decline any discussion on the justness of the proceeding, and openly appeal to the law of the strongest. The Melians then endeavour to persuade them, that their own interest would not be promoted by so violent a proceeding. The reply of the Athenians discovers the most unbounded confidence in their own good fortune, and in the power of their state, which nothing, they apprehended, can shake. The Melians, finding entreaties and argument fruitless, prepared to defend themselves by force of arms. Their resistance was long and vigorous; but, the island being at length taken, the Athenians completed their iniquity, by putting to death all the males above the age of fourteen, and selling the rest as slaves.

Such a violent and flagitious system soon hurried them on to their ruin. The island of Sicily had, for some time past, been desolated by violent internal wars. In these the Athenians had repeatedly taken a share; but so unwelcome was their interference, that it had united all the states of the island in a league for the exclusion of strangers. From this none dissented except the city of Eggesta, which had incurred the resentment of Syracuse and Selinus; apprehensive of being crushed by whom, the Eggestans sought the alliance of Athens. They gave, at the same time, an exaggerated statement of the resources, particularly pecuniary, which they themselves could supply. Nothing could be more imprudent for the Athenians, than to engage, at such a juncture, in a war almost equal in magnitude to the Peloponnesian. They were scarcely at peace with Sparta, which would doubtless avail itself of the first favourable opportunity of humbling them. They had a mighty rebellion to suppress, of their own dependencies, in the Chalcidice. But with the Athenians, always sanguine and adventurous, always aiming at what they did not possess, and thinking of aggrandizement rather than of safety, such considerations had little influence. Masters of Sicily, they would soon become masters of all Greece; nor was there any stretch of greatness to which they might not attain. Alcibiades, with all the young men devoted to him, and, in general, all the leaders of the popular party, strenuously supported a measure, from which the cautious prudence of Nicias in vain attempted to dissuade his countrymen. Even when the latter, hoping at least to procure a delay, gave an exaggerated statement of the preparations which would be necessary, the Athenians voted an immediate supply of

all he demanded. Nicias, Alcibiades, and Lamachus, were appointed commanders of the expedition.

The armament consisted of 100 gallees, with a number of transports and smaller vessels, having on board 5000 heavy armed troops, besides archers and slingers. Its rendezvous was at Coryra, whence it crossed over to the nearest point of Italy, and sailed along the coast till it came to the straits of Messina. Great expectations had been entertained from the Italian states, several of whom were bound by alliance and former favours; but all, jealous of such mighty interference, shut their gates against the Athenians. On their arrival off the coast of Sicily, the Egéstans were found altogether incapable of performing their promises. The question then came to be, What was to be done? Nicias proposed to return immediately; Lamachus to proceed without delay to Syracuse, before it had time to prepare, or to recover from its consternation. A middle plan prevailed, which was to sail round the coast, in order to collect resources and allies for the future siege of Syracuse.

Alcibiades proceeded first to Naxos and Catana, with both which cities he succeeded; but, as he was proceeding to Messana, a deputation arrived, commanding him to return to Athens. His enemies had taken advantage of his absence to press a charge of impiety, founded on the extraordinary circumstance of all the statues of Mercury having been found mutilated on the morning of his departure. It seemed countenanced by the habitual levity of his conduct. Alcibiades, aware of the little lenity exercised by Athens towards her great men, declined standing his trial, and retired to Sparta. It seems difficult to determine, whether his former influence, or his present disgrace, were most fatal to his country. Since the expedition was undertaken, he certainly, of all men, was best qualified to conduct it. The timid and irresolute character of Nicias, on whom the chief command now devolved, rendered him wholly unfit to conduct an enterprize which could succeed only by prompt and decisive measures. He spun out the summer in small and ineffective expeditions against the inferior states. By a skilful stratagem he drew off the Syracusan army to Catana, and was thus enabled to effect his landing without opposition. An engagement soon after ensued, in which the Syracusans were defeated: But Nicias, not conceiving himself to be yet in a state to finish the siege, immediately reembarked, and returned to spend the winter at Catana.

Early next spring Nicias, having received large reinforcements, seriously undertook the siege of Syracuse. The inhabitants defended themselves with bravery and resolution; but, as their troops were comparatively undisciplined, and their generals inexperienced, they were gradually pressed closer and closer, and at length reduced to such an extremity, that their fall seemed rapidly approaching.

The Lacedemonians could not observe, without the most extreme jealousy, the progress of the Athenian arms. Alcibiades, whose resentment had now impelled him to espouse their cause, strongly inculcated on them the necessity of vigorously opposing it. By his advice, they were induced to declare war against the Athenians, to send an army into Attica, and to fortify Decelia, which might give them a permanent establishment in the Athenian territory. At the same time they sent Gylippus, an able commander, with a body of select troops, to the aid of the Syracusans. The Corinthians, at the same time sent a large fleet for the same purpose. Encouraged by

the prospect of succour, the Syracusans renewed their efforts. Gylippus landed on the western coast, was joined on his march by the troops of Selinus, Gela, and Himera, and entered Syracuse in considerable force. Two actions followed, in the first of which he was repulsed, but in the second he defeated the Athenians with considerable loss. Animated by this success, the Syracusans, now reinforced by the Corinthian squadron, determined to attack the enemy on their own element. After several failures, they at length succeeded in defeating them there also; an event which filled them with the highest exultation. All Sicily now declared against the declining fortune of Athens; the supplies of provisions were withheld; and the armament gradually mouldered away, while that of the enemy received continual accessions.

In this distress Nicias wrote home, urging strongly the necessity, either of his immediate recall, or of large reinforcements. Never could the latter demand arrive more unseasonably. The Lacedemonians, according to the advice of Alcibiades, had fortified Decelia, and were thus enabled, both to keep Athens in perpetual alarm, and to cut off all supplies of provisions, unless by sea. Yet such was the daring enterprize, and vast resources, of this state, that instead of recalling Nicias, they fitted out, without delay, an armament nearly equal to that originally sent. The unexpected appearance of so mighty a reinforcement inspired the assailants with new courage, while it struck the besieged with dismay. It was commanded by Demosthenes. By his advice a general attack was resolved on. It was undertaken accordingly by moonlight, against the quarter of Epipolæ; having gained which, they hoped to possess themselves of the whole city. They at first succeeded; Epipolæ was forced; but when the Athenians pressed forward to pursue their advantage, the darkness of the night, and their ignorance of the place, threw them into inextricable confusion. They were unable to distinguish between friends and foes; the enemy gained their watchword; and after a dreadful combat, they were repulsed with great slaughter.

Demosthenes now advised an immediate return; but this proposal was unexpectedly opposed by Nicias, who dreaded to appear before the enraged assembly of Athens, and entertained hopes, from secret connections which he had formed in the city. Things remained in this state, till Gylippus arrived with a powerful reinforcement, which he had collected from the different states of Sicily. The necessity of departing was now obvious to all; but an eclipse of the sun happening, Nicias, from a principle of superstition, to which he was miserably addicted, conceived it necessary to delay their departure for twenty-seven days. This was a fatal delay to Athens.

The Syracusans, encouraged by their increased numbers, and by the evident irresolution and timidity of their enemies, determined to attack them on their own element. A naval engagement took place, and continued for three days with various success. The valour and skill of the Athenians at first prevailed; but the Syracusans, continually pouring in fresh numbers, at length gained a considerable advantage.

No choice now remained to the Athenians but of immediate retreat. By the time, however, that they had brought their fleet to the mouth of the harbour, they found that the Syracusans, without losing a moment, had thrown a chain across it. Another battle was therefore necessary before they could escape. On

this battle hung the fate of the whole Athenian armament. It was fought long, and with dreadful obstinacy.

The armies surrounding the harbour, beheld it as from a theatre, and raised cries of alternate exultation and despair, according to the varying fortunes of the day. Victory at length decided against the Athenians; all their vessels fled, and were driven on shore. Nothing could then exceed their calamity. Their only hope was to escape by land to some of the allied cities; but the route was to be made in the face of a victorious enemy, through a country every where hostile. As in a city taken by storm, they were to fly, having lost their all. They were forced to abandon their dead unburied, a thing never before done by an Athenian army; they were forced even to abandon their wounded, exclaiming in vain to gods and men against this inhuman desertion. The character of Nicias rose in misfortune. By every motive of hope, of interest, of national honour, he endeavored to rouse his countrymen from despair, and to inspire them with that firmness which alone could save them. Yet, the usual tardiness of his character remaining, he wasted two days in preparation, of which period the Syracusans availed themselves to sieze on the passes. The Athenian army, however, for some time forced their way, though slowly, through crowds of surrounding enemies. At length, the rear guard under Demosthenes was separated from the van, and forced to surrender, stipulating only for their lives. The catastrophe of Nicias was still more fatal. Having reached the banks of the river Asinarius, he made a desperate attempt to cross it, conceiving that his retreat would then be secure. The enemy, however, had possessed themselves of its steep banks, and had filled them with armed men. The Athenians, raging with thirst, plunged into the stream, and eagerly drank it, mixed as it was with the blood of their countrymen. The crowds pressing on confusedly encumbered and crushed each other; their attempts to advance were vain; while showers of darts were incessantly poured down upon them from the surrounding heights. In this dreadful condition, Nicias, seeing all was lost, agreed to surrender on the mere condition of the carnage being stopped. The prisoners were conducted to Syracuse, and were treated with the utmost barbarity. Nicias and Demosthenes were put to death.

We may more easily conceive than describe the consternation of the Athenians, when these fatal tidings arrived; when instead of their vain and towering hopes of universal conquest, they saw themselves exposed almost defenceless, to the fury of their enemies. The flower of their warriors had perished; and their subject-allies, whom fear alone had retained in submission, began to manifest symptoms of revolt. In this extremity, the energy of popular government, tempered by misfortune, fully displayed itself. The most able and prudent persons were set at the head of affairs; a new fleet was equipped with incredible dispatch; armaments, sent to Chios, Samos, and Ionia, secured the allegiance of those states; and Athens appeared, to astonished Greece, as formidable almost as she had been in her most prosperous days.

The characteristic slowness of the Lacedemonians had prevented them from availing themselves of the first consternation of Athens, and seeing her rise so rapidly to her former greatness, they began to be discouraged from the farther prosecution of the war. Alcibiades, however, urged them to proceed, and endeavoured to strengthen them by the alliance of the Persians. Finding, however, that his levity and dissoluteness had ruin-

ed his influence at Sparta, he went over entirely to the latter; and finally hoping to regain his footing in Athens, offered to secure for it the Persian alliance, provided an aristocracy were established, and placed under his authority. The Athenians, feeling the urgency of their affairs, and disgusted with the party which had impelled them into such precipitate measures, suffered their consent to be extorted to a change so repugnant to all their former habits. A singular manœuvre now took place. Pisander, Antiphon, and other old aristocrats, determined, that since this change was to take place, it should be for the benefit of themselves, rather than of one so odious to them as Alcibiades. In his absence, therefore, they procured the consent of the Athenians to adopt a new system of government, in the room of that which they had so long idolized. The popular assembly was reduced to 5000, by excluding the lowest of the people; while the chief power was vested in a council of 400; and, these being all chosen ultimately by five *prytanes*, the whole authority centered in the latter.

This government subsisted for some time without opposition. The people, however, soon grew impatient of restraints to which they were so little accustomed; and the new rulers, by abusing their power, aggravated the discontent. In foreign states, too, the aristocratical party, on finding themselves, to their extreme surprise, placed in power by the Athenians, chose rather to trust to the long-tried friendship of Sparta, than to this sudden favour of their inveterate enemies. Several important cities were thus lost to Athens. Meanwhile the army, with Thrasybulus and Thrasyllus at their head, loudly protested against the subversion of Athenian liberty. They recalled Alcibiades, who with characteristic inconstancy, now embraced the cause of democracy. By his eloquence he charmed all hearts, and soon acquired an absolute ascendant over the troops. He gained over Tisaphernes to the side of Athens; and under his own command, and that of Thrasybulus, every thing prospered. The latter, with 55 vessels against 75, gained a victory over the Peloponnesians, taking 21 of their ships. Soon after Alcibiades gained a still more signal victory at Cyzicus. By a skilful stratagem, he surrounded the enemy, drove them on shore, took almost their whole fleet, and then landing, put their army to flight.

Meanwhile all was disaster and confusion at Athens. In vain did the aristocratical leaders endeavour to conciliate the people by changes in the government; the discontents rose higher and higher, when a Lacedemonian fleet of 40 sail appeared in the bay of Salamis. Without, however, making any attempt upon Athens, it sailed to Eubœa; but the Athenian fleet sent to oppose it was completely defeated. This disaster produced the immediate dissolution of the new government: Pisander and his accomplices fled to the Lacedemonians: the people resumed their power, and exerted themselves with their wonted activity, in repairing their losses. Alcibiades was made commander in chief, and continued his career of victory, by reducing Byzantium, and other great towns on the Thracian coast, always a favorite object of Athenian ambition. He then returned to Athens, where every honour was lavished upon him which ingenuity could devise; and where he distinguished himself, by conducting the procession of the Elusinian mysteries in safety from Athens to Eleusis, which had not been effected since the loss of Decelia.

Alcibiades was now again sent out with the full command of the fleet; but having gone in person to raise

contributions, he left the command of it to an unworthy favorite of the name of Antiochus, who having rashly left the harbour, and being attacked by Lysander near Ephesus, was entirely defeated. The tide of popular favour was instantly turned; Alcibiades so late its idol, was dismissed from all his employments, and banished. Ten commanders were then appointed, who seem to have been well chosen, since, besides Thrasybulus and Thrasyllus, they included Conon, one of the greatest of the Athenians, who now for the first time appears on the theatre of history. His first enterprise was however unfortunate. Being sent with an inadequate squadron to relieve Lesbos, he was overpowered by numbers, and blocked up in the harbour of Mitylene. The Athenians made extraordinary exertions to relieve him. A fleet of 150 sail was soon fitted out, and sent thither under the command of the other admirals. A battle was then fought at Arginussæ, in which the Athenian fleet was completely victorious. Theramenes, however, one of the commanders, raised an accusation against the rest, for having neglected the bodies of the slain, and even for having abandoned a number of shipwrecked citizens, whose lives might have been saved. The people, in a paroxysm of frenzy, condemned to death all who had not sought safety in flight; and six of the best Athenian commanders, among whom were in particular Thrasyllus, Diomedon, and the only son of the famous Pericles, were executed.

Conon was now placed at the head of the fleet; but all his measures were cramped by unworthy colleagues, who were associated with him. Meanwhile the Lacedæmonians determining to make a great effort, had fitted out a large armament, and entrusted the command of it to Lysander, the most able and enterprising of their officers. Lysander immediately proceeded to lay siege to Lampsacus, which he took after an obstinate defence. The Athenian fleet arrived too late to save it; but being superior in number, it offered battle. The offer was declined by Lysander, who kept himself shut up in the harbour of Lampsacus, and assumed a studied appearance of alarm and consternation. The Athenians, after battle had been thus declined for five successive days, retired and anchored in the river of Ægos Potamos, on the Thracian side of the Bosphorus. They now abandoned themselves to the utmost excess of exultation and security. They straggled on shore, threw aside all restraint of discipline, and indulged in every kind of licentiousness. Their motions were carefully watched by Lysander, who, at length conceiving the opportunity favourable, fell upon them suddenly with his whole force. They were so completely unprepared, as to be hardly in a condition to make even a show of resistance. The whole fleet of 180 sail, with the exception of nine ships, fell into the hands of the victors. Lysander then landed his army, and gained an easy victory over the detached and straggling bands of the Athenians. The few who escaped sought safety among the mountains in the interior of Thrace. Conon, after vain attempts to rally his countrymen, found means to escape with eight gallees to Cyprus.

This blow was mortal to Athens; yet she still continued, for some time, to protract a languishing existence. Lysander did not dare at once to attack her almost impregnable walls and harbours. He contented himself, for the present, with reducing or alienating those maritime states which she had so long held in subjection, particularly the rich and advantageous settle-

ments on the coast of Thrace. He at the same time closely blockaded the city by sea and land, and, to increase the want of provisions, obliged the garrisons of the captured places to return into the city. Athens was soon reduced to extreme distress; yet still, with a resolution worthy of her former greatness, she struggled against her fate. Her liberty, however, was assailed, not only by foreign, but by intestine enemies. The party attached to the Lacedæmonian form of government, hoped, by the success of that people, to establish themselves in power. This party gained continually new strength, as the probable æra of their triumph approached. At length Theramenes, a new convert to this party, but whose former conduct had gained him the confidence of the people, procured their consent to the opening of a treaty with Sparta. The negotiation continued four months, and was concluded on terms the most disgraceful and ruinous to Athens. All the fortifications both of their city and harbours were to be demolished: they were to renounce all their foreign possessions; to receive back the banished aristocrats; to follow in war the standard of the Lacedæmonians; and to become in every respect on a footing with the rest of their subject allies. These terms were received by the body of the people with the deepest consternation; but their spirit was now broken by a long series of calamities; the aristocratical party were clamorous; and a gloomy and reluctant consent was at length extorted. On the sixteenth of May, A. C. 404, in the 27th year after the commencement of the Peloponnesian war, the Lacedæmonians entered Athens. Even the victors could scarcely refrain from tears, when they beheld this final humiliation of a city, formerly so great in arms, which had once been the deliverer, and had so long reigned the arbitress of Greece.

Sparta, according to the usual system of Grecian policy, did not reduce Athens to absolute subjection: She merely established in power the party in whose friendship she could confide. Thus the government remained in the hands of Athenians, though the Lacedæmonians took the precaution of placing a garrison in the citadel. It was moulded, however, into a system of the most complete oligarchy. The authority was exclusively vested in 30 persons, who, from the violence of their proceedings, and the eternal hatred of Athens to such a government, soon acquired the appellation of the Thirty Tyrants. At the head of them was Theramenes, already mentioned, and Critias, who was still more violent. They were inspired with the usual antipathy of Greeks to the opposite faction, and exasperated by the remembrance of what they had suffered from them. At the same time, the extraordinary strength of the popular spirit in Athens excited continual apprehensions, which could be quieted only by acts of severity. Their first proceedings were directed against the most obnoxious of the opposite party, whose punishment gave satisfaction to the people in general. Emboldened by this success, and urged on by avarice and fear, they proceeded to exercise a general proscription against the innocent and guilty. Every form of justice was by degrees trampled upon; all the citizens, except 3000 devoted adherents, were deprived of their arms; while Theramenes, who attempted too late to stem this torrent of violence, was accused and put to death.

Amid every precaution which cruelty could devise, the tyrants still did not feel themselves secure. They dreaded the talents and address of Alcibiades; and Ly-

sander, by his interest at the Persian court, procured him to be put to death. The storm, however, came from a quarter which they least expected. Thrasybulus, who had already distinguished himself as a successful commander, was exiled, with many other citizens of distinction. This person, having collected a few hundreds of other exiles, who had taken refuge at Thebes and its neighbourhood, seized upon Phyla, a small fortress on the confines of Attica and Bœotia. The tyrants were baffled in their first attempt to expel him; this success attracted numbers to his standard; and he soon found himself sufficiently in force to form the bold design of seizing on the Piræus. In this attempt he succeeded: the tyrants, endeavouring to dislodge him, were defeated with great slaughter, and took shelter in the citadel, while part fled even to Eleusis.

The Lacedæmonians seem, on this occasion, to have displayed more than their usual tardiness. They did not rouse themselves till some weeks after the expulsion of their adherents from the Piræus. Then, however, Lysander marched with a formidable force, which Athens could not long have resisted, had not divisions arisen among the Spartan chiefs. All parties in Sparta had become jealous of the overgrown power and influence of Lysander; and Pausanias, one of the kings, having been joined with him in the command, thwarted all his measures. Through the influence of this monarch, a negotiation was set on foot, which terminated in the removal of the Lacedæmonian garrison, and the complete re-establishment of the independence of Athens. The tyrants vainly endeavoured to defend themselves in Eleusis; they were speedily reduced; several suffered, and the rest were spared by the clemency of Thrasybulus.

The Athenians were not long of making an ill use of their liberty, by the condemnation and death of Socrates, the best and wisest of their citizens. For the particulars of this event, we must refer to the life of that great man.

Athens had often astonished Greece by the rapidity with which she rose from her ashes; but never was this elastic power more conspicuous than on the present occasion. Conon, of whom mention has already been made, was the chief artificer of her new greatness. Having formed an alliance with Evagoras of Cyprus, and with the Persian court, he was enabled to collect a formidable navy. With this he attacked the Lacedæmonian fleet at Cnidus, under the command of Pisander, totally defeated it, and took 50 gallees. The maritime superiority of Athens was now restored, and the fine settlements on the coast of the Lesser Asia, accessible only by sea, were soon reduced again under her dominion.

Conon now returned to Athens, and, with the aid of Persian treasure, actively employed himself in re-building the walls, without which she could never have enjoyed any lasting security. This measure, joined to the successes of the Athenians, struck Sparta with alarm. She now endeavoured to reconcile herself with Persia, against whom she had for some time been waging a successful war. Her intrigues were forwarded by the conduct of Conon, who, as was too common among the Grecian states, preferring patriotism to justice, employed the Persian fleet almost wholly in forwarding Athenian objects. Through the skillful mediation of Antalcidas, Lacedæmon concluded that treaty which goes by his name. By it she ignominiously abandoned

to Persia the colonies of the Lesser Asia, which had now become, in her eyes, a secondary object. With regard to Greece, she stipulated for the freedom of the smaller cities; but by never executing this article herself, and only insisting on its being executed by others, she made it the means of rendering her authority paramount in Greece. Athens, however, being allowed also to retain her possessions, made no movement.

Sparta now proceeded under the guidance of Agesilaus, to extend her usurpations over the states of Greece. Mantinea and Thebes, the two most powerful states next to Athens, were subdued, the one by force, the other by stratagem. Thebes, however, under the auspices of Pelopidas, soon re-asserted her independence, and began a career of success, which set bounds to Spartan encroachment. Athens, however, did not interfere, till one Sphodrias, a Spartan officer, secretly instigated by the Theban chiefs, made an attempt to surprise the Piræus. His project was discovered and frustrated; but when the Athenians demanded satisfaction, the influence of Agesilaus screened the offender from punishment. Athens then took up arms, and, while the Thebans were carrying on the war by land, obtained important naval advantages. Under the conduct of their distinguished leaders, Chabrias and Timotheus, they repeatedly defeated the Lacedæmonians, ravaged their coasts, and re-established their own influence over the maritime states. After, however, the battle of Leuctra had raised Thebes to the highest pitch of power, and reduced her rival to the utmost distress, the Athenians, jealous of this new influence, began to slacken their efforts, and at length were even induced to interfere in behalf of Lacedæmon. An army, sent into Peloponnesus under the command of Iphicrates, compelled the Thebans to retreat into Bœotia. Their promptitude also frustrated an attempt made by Epaminondas to supplant them in the dominion of the sea. A large body of Athenian cavalry was present at the battle of Mantinea, and though the rest of the allied army were defeated, this part was victorious.

Thebes and Sparta being now worn out by mutual contests, Athens, which had for some time acted only a subordinate part, again rose to be the leading power in Greece. There were many circumstances, however, in her internal constitution, which kept her far beneath the level of her ancient greatness. The democracy had now acquired a complete and uncontrolled ascendancy; the preceding convulsions had annihilated all the former checks on its licentiousness. The most worthless demagogues held the chief sway; and the levity, characteristic of a popular assembly, had risen to such a height, that a measure decreed was almost as uncertain as if it had never been proposed. They retained all their former enterprising and ambitious character, but were no longer disposed to employ the same means of rendering their resolutions effectual. The bearing of arms was now considered as a burdensome duty: "the sovereign people," says Mr Mitford, "more and more dispensed with their own services." Metics (a mixed race between freemen and slaves) and foreign mercenaries, were soon exclusively employed in the army; and though the sea service, formerly the least honourable, was now preferred on account of its opportunities of plunder, yet it gradually fell into the same hands. Such troops, acting without any motive to animate them or secure their fidelity, did no honour to the Athenian name. Athens, indeed, even in her last decline, was

still fruitful of great men, but these were resorted to only on pressing emergencies; at all other times, the command was vested in those who could best flatter the passions of the people. In the better times of the republic, the same person had united the characters of orator and general; these were now separated; and every commander had an orator attached to him, who supported his interest in the popular assembly.

Unfortunately, about this time a power arose, to withstand which would have required the utmost exertions of Athens in her best days. Macedon, remote and barbarous, had hitherto been scarcely numbered among the Grecian nations; but the activity of some of her late sovereigns had improved her civil and military constitution; and, in this last respect, she now united all the energy of a barbarous people with the arts of a civilized one. Philip had recently ascended the throne; a prince of the highest accomplishments, both as a warrior and statesman, ardently ambitious of extending his dominions, and acquiring an influence in the general concerns of Greece. The first subjects of contest were the towns on the Thracian coast, which were equally objects of ambition to the two parties. The Athenians, urged particularly by the hope of recovering Amphipolis, had sent a force in support of Argæus, a pretender to the crown of Macedon. Argæus and his auxiliaries were completely defeated; but Philip, who felt it to be still his interest to court the favour of the Athenians, and who was ambitious of the fame of clemency, not only dismissed his prisoners without ransom, but agreed to withdraw his claims upon Amphipolis, and to allow the Athenians an opportunity of regaining that favourite object of their ambition. Amphipolis endeavoured to protect itself, by joining a grand confederacy of Thracian cities, which had Olynthus for its head. A ground of dissension was thus established between Athens and Olynthus, which proved equally prejudicial to both, whose interest it was to have united against Philip. Athens, however, sent an armament against Amphipolis, under the command of Iphicrates. That general reduced the city to extremity, and brought it to accept of a capitulation; but as the conditions were on the point of being executed, Timotheus arrived with a commission which superseded that of Iphicrates. The inhabitants, who had trusted to the personal character of the commander, rather than to the faith of the Athenian state, refused to place the same confidence in another man; the negotiation was broken off; and the Athenian mercenaries having slipped away, the whole enterprize failed.

This good understanding did not long continue between two powers so restless and ambitious. There appears reason to suspect, that the Athenians, finding, through the disposition of the people, an opportunity to take possession of Pydna, a Macedonian city, did not scruple to avail themselves of it. Philip, therefore, having freed himself from his enemies on the side of Illyria and Thrace, and seeing no longer any thing very formidable in the military character of the Athenians, formed an alliance with Olynthus against them, and subdued Amphipolis, Pydna, and Potidæa. To cement his alliance with Olynthus, as well as to maintain the character of ostentatious generosity, which he affected, he presented that state with the two last mentioned cities.

Athens was withheld from resisting these advances, not only by her internal feebleness and disunion, but by two other wars, in which she was, about this time, in-

olved. The sacred war was then raging in Phocis; an event of which the details will be found in their proper place. The Athenians engaged in it as auxiliaries to the Phocians; but though they seem to have espoused the justest cause, yet they escaped not the suspicion of having been biassed, by receiving a share of the treasure of which the Phocian leader Philomelus had impiously despoiled the temple of Delphi. They rendered, however, an important service to Greece, by barring the pass of Thermopylæ against Philip, who, having already established his influence in Thessaly, had eagerly embraced the imprudent invitation of the Amphictyons to place himself at their head.

Another and a more interesting event now excited the attention of Athens. We have already adverted to the oppressive sway which she exercised over her subject allies. This was carried to a much greater height, when the command fell into hands equally weak and profligate. Till now, the Athenians had always, with little distinction of party, placed the most able officers at the head of their armaments. Of these, they still possessed abundance; and Chabrias, Timotheus, and Iphicrates, were well calculated to support the reputation of the Athenian name. To them, however, the populace now preferred Chares, a partizan of some activity and enterprize, but totally unfit for the management of great affairs, and who conciliated the favour of the people, by flattering their passions, and by distributing among them his ill-gotten plunder. Being repeatedly vested with the command of the fleet, his exactions became at length so enormous, that several of the principal dependencies, Rhodes, Chios, Cos, and Byzantium, threw off the yoke, and openly asserted their independence. Hence arose what is called the *Social War*.

This intelligence struck Athens like a thunderbolt. The people were so far roused to activity, that they immediately equipped a powerful fleet, and sent it against Chios. Chares had the chief command, with Chabrias under him. He was repulsed, however, in his attack on the harbour, and Chabrias, who alone entered, refusing to retreat, was slain; an irreparable loss to his country. The confederates, encouraged by this success, attacked the important islands of Samos and Lemnos. The Athenians, recalled to some measure of wisdom, sent a new armament under Timotheus and Iphicrates. These commanders forced the enemy to relinquish their enterprize; but having declined to fight in a disadvantageous situation, were denounced to the people by Chares. Their trial was instituted; and though they escaped the punishment of death, yet such a fine was imposed upon both, as amounted to banishment. The object of the accusation, however, was attained. The sole command of the fleets and armies of the republic devolved upon Chares, by whom they were so completely mismanaged, that no progress whatever was made in the reduction of the revolted states. Chares, too, having for a sum of money assisted Artabazus, satrap of Ionia, against the king of Persia, drew upon Athens the resentment of that monarch. In addition to this, the increasing pressure from Macedon and other quarters at length reduced her to the humiliating necessity of agreeing to a peace, by which she acknowledged the entire independence of the revolted states.

We return now to the affairs of Macedon. Two parties then divided the Athenian councils. One perpetually recommended peace and friendship with that power, while the other breathed only war and hostility. The

former consisted partly of the devoted adherents of Philip, and partly also of a description of men, by far the most respectable in Athens, who were abundantly sensible of the danger arising from this quarter. Seeing, however, that the state was now totally unable to contend with the power of that monarchy, the preponderance of which was increased by every new war, they advised a moderate and conciliating system as the only means of preserving to Athens what still remained. Isocrates and Phocion were the heads of this party. In the other, the lead was now taken by Demosthenes. His ardent and glowing mind, conceived the idea of reviving the glory of Athens, and making her all that she had formerly been. While, therefore, he impelled his countrymen to the most daring enterprizes, he at the same time pointed out the means by which these could be brought to a prosperous issue. He urged the necessity of no longer wasting the public treasure on theatrical representations, and of taking up arms themselves, instead of filling their armies with mercenaries. The Athenians, in the decline of their valour, still retained all their ambition, so that he commonly succeeded in his first object, of engaging them in bold and adventurous undertakings; but he in vain endeavoured to make them submit to those privations, which were indispensably necessary for their prosecution. Thus the influence of this party was injurious, both from what it did, and from what it did not accomplish. On the other hand, the party of Phocion, without being able to check the rash schemes of their adversaries, seem only to have embarrassed the execution of them. Thus every thing conspired to the fall of Athenian greatness.

On one occasion, the people discovered some marks of their former activity. Philip had contrived to gain a powerful party in Eubœa, which, availing itself of the small number of Athenian troops kept there, succeeded in gaining an ascendancy, and thus threatened to deprive Athens of that important island. This danger was too imminent to be neglected. An armament was immediately equipped and committed to Phocion, now the only great commander remaining to Athens. Phocion, acting with his usual skill and judgment, was not long of defeating the Macedonians and Eubœan malcontents, and of compelling the former to evacuate the island.

The alliance between the Olynthians and Philip was not likely to last long. The possession of the Thracian coast was a primary object of ambition to that monarch; and when he had disengaged himself from other objects, the restless character of this state, full of Athenian partizans, soon afforded him a pretence. The interest of Athens could not be mistaken. A strict alliance was immediately concluded between the two republics, and the Athenians, in compliance with the urgent intreaties of Demosthenes, seriously resolved on a prosecution of the war. As they were in vain entreated, however, to retrench in their expensive amusements, or to submit to the hardships of personal service, every thing went on slowly and languidly. A few mercenary troops were hired, and put under the command of Chares. That general, however, instead of aiding the Olynthians, employed himself in his usual occupation of ravaging the coasts, and plundering the allies; and, having enabled himself, on his return, to give a splendid feast to the people, was hailed with acclamation. New ambassadors, however, soon came from Olynthus, to remonstrate on the inefficacy of this expedition. Another was then fitted out, and a small body of mercenaries at last thrown

into Olynthus. This, however, proved but a feeble barrier to the progress of Philip. Having successively reduced city after city, he was now pressing the siege of the capital, which, after a long and obstinate resistance, was reduced to the last extremity. The Athenians, on learning this distress of their ally, began at last to set a formidable expedition on foot; but just as it was on the point of sailing, intelligence arrived, that its object was no more, and that Philip was now master of Olynthus.

Philip having obtained this extent of sea coast, was not long in equipping a formidable navy, which enabled him to make the Athenians feel the hardships of war, even in their own country. He ravaged the coasts of Attaca; he landed a body of troops in Eubœa, which, joined to the party that still adhered to him among the inhabitants, enabled him to regain the ascendancy in that island. The spirit of the Athenians was broken by such a succession of calamities; and Philip having, in conformity to his usual system, been the first to make pacific advances, all parties seem to have agreed in the propriety of sending an embassy to him. Among the ambassadors were Demosthenes and Æschines, both hostile to that monarch. Demosthenes, in this new character, did not maintain his former reputation, while all admired the politeness and eloquence of Philip. Through the arts of that monarch, aided by the volatility of the Athenian people, the negotiation was protracted; successive embassies were sent; while Philip, availing himself of these delays, was crushing Kersableptes, the ally of Athens, and maturing his designs against the liberties of Greece. At length, having gained a body of mercenaries, who defended Nicœa, he obtained possession of that important fortress, and through it of the pass of Thermopylæ. He then lost no time in entering Greece, where, supported by the Thebans, Thessalians, and Locrians, he soon crushed the Phocians, and gave them a prey to the unrelenting vengeance of their enemies, which, however, he interfered to mitigate. He then procured his appointment as general of the Amphictyons, which afforded him a pious pretence for interposing whenever he thought fit, in the affairs of Greece. In this new character, he left a garrison in the citadel of Thebes; and supporting his affected character of moderation, withdrew his army, for the present, out of Greece.

The Athenians were struck with mortal alarm, when they received intelligence that Philip was establishing himself in the heart of the Grecian states. Demosthenes, who had long warned them of this issue, now acquired additional influence. This advantage, joined to the growing fame of his eloquence, enabled him for some time to exert an almost undivided sway over their councils, and to communicate to them an expiring energy, to which they had long been strangers. Yet it was conceived necessary, under present circumstances, to admit Philip's title of general of the Amphictyons, and not, by denying it, to provoke an immediate war. They held themselves, however, in a state of preparation to resist any farther encroachments.

The first object to which Demosthenes directed the attention of the Athenians, was Eubœa. The Macedonian party had already lost considerable ground in that island by their violence and oppression. When Phocion, therefore, was sent with an armament, accompanied by Demosthenes, the eloquence of the one, and the military skill of the other, soon brought back the island to the dominion of Athens.

Philip was soon after foiled in a still more sensible point. He had long cast an eager eye on Byzantium, Perinthus, and Selymbria, cities great and opulent in themselves, and important from their command of the Thracian Bosphorus, the key of the Euxine. Thinking this a favourable opportunity, he had commenced operations against them, but met with a vigorous resistance. Demosthenes urged the Athenians to a vigorous support of these cities; armaments were accordingly fitted out; and though the first was rendered fruitless by the ill-conduct of Chares, yet the second, being entrusted to Phocion, was effectual in relieving the Thracian cities, and in forcing Philip to relinquish his designs in that quarter.

Philip, finding himself thwarted in this point, directed his attention to another, which appeared more promising. His emissaries in Greece succeeded in kindling a new sacred war against the Amphissians, a people of Phocis, and in procuring an invitation for Philip, as general of the Amphictyons, to take the chief command. Philip eagerly grasped at the offer; escaped, by a stratagem, the Athenian fleet, and landed a strong body of troops on the coast of Locris. The Athenians were excited by Demosthenes to send an army of ten thousand mercenaries to the assistance of Amphissa. This force, however proved too feeble to resist the powerful army of Philip: Amphissa was subdued, and suffered a severe punishment for its alledged impiety.

All the cities of Greece, Thebes itself not excepted, were struck with the deepest alarm at this rapid progress of Philip. The Athenians, obedient to the call of Demosthenes, summoned all their strength, and marched it to the frontiers. The orator himself went from city to city, rousing every where the hatred of the people against the Macedonian power. An extensive confederacy was formed, consisting, besides Athens, of Megara, Corinth, Achaia, Leucas, Corcyra, and Eubœa; while Thebes itself evidently wavered. Alarmed by this formidable combination, Philip seized Elatea, an important post, which at once secured his communication with Thessaly, and opened an entrance into Bœotia. This step at once roused Athens to action, and fixed the wavering councils of Thebes. The latter city took now a decided part in the confederacy against Macedon. Demosthenes acquired the same ascendancy in its councils as in those of Athens; the armies of the two states united, and prepared to commence operations against the common enemy.

It is impossible to deny to Demosthenes the praise of activity and vigour in bringing affairs to this crisis. He was now, however, guilty of errors, which frustrated the effect of his former exertions. With the most shameful devotion to party-spirit, he overlooked Phocion, the only great commander whom Athens still retained, and appointed in his stead Chares, whose incapacity had been so often conspicuous. To him was joined Lysicles, a personage never before heard of. A capital error seems also to have been committed in the plan of the war. Against Philip, placed as he was in a mountainous territory, and at a distance from his resources, protracted and harrassing hostilities might probably have been successful; but the Grecian levies, little accustomed to war, were ill calculated for coping in the field with his hardy veterans. These considerations were overlooked; when Philip advanced and offered battle, it was not declined; and the two parties, each with about thirty or

forty thousand men, prepared to decide the fate of Greece on the plain of Cheronœa.

The contest was severe. The Thebans were placed on the right wing, the Athenians on the left. The latter, though opposed by Philip in person, were for some time victorious; but, pursuing too hotly, exposed themselves to an attack of the Macedonian phalanx, which soon changed their victory into a defeat. The Thebans also, after an obstinate resistance, were routed, and their sacred band entirely cut to pieces. Philip obtained a complete triumph; while Greece, and above all, Athens, received that mortal blow, from which they never recovered.

It was generally expected, that Philip would avail himself of this opportunity of crushing entirely this inveterate enemy. That prudent prince, however, foresaw, that powerful obstacles were yet to be encountered, and that there was still a spirit in the Athenian people which might render it difficult to hold them in complete subjection. It would appear also, as if the genius and fame of Athens had, in this hour of her calamity, thrown a shield over her. Philip is reported to have said, "Have I done so much for glory, and shall I destroy the theatre of that glory?" Certain it is, that he shewed an anxiety to gain Athens only by conciliation. He dismissed the prisoners without ransom, gave them even their baggage on being asked, and proposed terms of accommodation, which were not only moderate, but advantageous. The Athenians first spurned the idea of existing by the clemency of Philip, and prepared rather for every extremity of resistance. This display of spirit only served to make Philip adhere the more steadily to his first offers; moderate advices prevailed; and a treaty was at length concluded, by which they retained the whole Attic territory, with the addition of Oropus, a Bœotian city. Lysicles was put to death; but whether deservedly, or as a victim to public resentment, does not distinctly appear.

Such was the final termination of the power and greatness of Athens. From this moment her political existence ceased. Here, therefore, it may be proper to pause, and before tracing the more obscure thread of her subsequent fortunes, take a short survey of what she was during that splendid period, when liberty raised her to the summit of glory, in arts and in arms. We shall begin with a view of her external aspect; we shall then survey her political and moral constitution; and, lastly consider her wonderful proficiency in the arts and sciences.

Athens was situated on the Saronic gulf, opposite to the eastern coast of Peloponnesus. It was inclosed in a sort of peninsula, formed by the confluence of the Cephissus and the Ilissus. From the sea, on which its greatness and importance so essentially depended, it was distant about four miles. It was connected, however, by walls of great strength and extent, with the three harbours of Piræus, Munychia, and Phalerus. The former, though the last of being erected, was soon found the most commodious and important of the three, and became a sort of emporium of Grecian commerce. A bay, formed by projecting rocks, furnished a species of triple harbour, at once spacious and secure; and the surrounding shore was covered with edifices, the splendour of which soon rivalled those of Athens itself. These harbours were joined to the city by a double range of walls, called the *long walls*, of which the north side, called

tending to Piræus, was five miles; the south, which branched off to Phalerus, was four miles and a quarter in length. That encompassing the Piræus with Munychia, was seven miles and a half. The long walls were built of hewn stone, and were so broad, that carriages could cross each other upon them.

In the centre of the city itself, and constituting its chief ornament, stood the *Acropolis*, the glory of Grecian art. On this elevation the whole of Athens was originally built; but as the city extended, the Acropolis came to serve merely the purpose of a citadel. Here, as in the safest and most conspicuous situation, were accumulated, all those works of ornament, of which Athens was so prolific. The Acropolis became the grand depository for every thing most splendid which human genius could produce, in painting, sculpture, and architecture. Its chief ornament was the *Parthenon*, or virgin temple of Minerva. This splendid edifice was 217 feet in length, and 98 in breadth. Destroyed by the Persians, it was rebuilt by Pericles, with great additional splendour. Within was the statue of Minerva by Phidias, the masterpiece of the art of statuary. It was of ivory, thirty-nine feet in height, and entirely covered with pure gold, to the value of forty four talents, or 120,000*l.* sterling. The *Propylea* also, of white marble, formed magnificent entrances to the Parthenon. This edifice was on the north side of the Acropolis, and near it was the Erechtheum, also of white marble, consisting of two temples, one of Minerva Polias, another of Neptune, besides a remarkable edifice called the Pandroseum. In front of the Acropolis, and at each end, were the two theatres, called the theatre of Bacchus, and the *Odeum*; the one designed for dramatic representations, and the other for music. Both, and particularly the last, were of extraordinary magnificence.

Although, however, the principal treasures of Athenian art were accumulated in the Acropolis, the city itself contained many noble structures. Among these we may particularly mention the *Pæcile*, or gallery of historical engravings; the tower of the Winds, by Andronicus Cyrrestes; and numerous monuments of illustrious men. Two of its most splendid ornaments, however, were without the walls. These were, the temples of Theseus and of Jupiter Olympius, situated the one on the north, and the other on the south side of the city. The former was Doric, bearing a considerable resemblance to the Parthenon, and having the achievements of this hero carved on the metopes. The temple of Jupiter Olympius was Corinthian, and surpassed, if possible, every other structure of which Athens could boast. Immense sums were spent upon it by the Athenians; additions were made to it by successive sovereigns; and at length the fabric was completed by Hadrian. The exterior contained about 120 columns, fluted, sixty feet in height, and six in diameter. The inclosure was half a mile in circumference.

Besides these wondrous productions of art, Athens presented other scenes, sacred in the eyes of posterity by the classical associations which they awaken. The ancient philosophers did not, as has been usual with modern men of letters, immerse themselves in the smoky atmosphere of cities. They sought retirement, and the scenes of nature; nor did the zeal of their disciples scruple to follow them. The Academy, where Plato taught, was about three-quarters of a mile to the north of the town. From being a marshy and unwholesome spot, it was gradually improved, planted with trees, and

refreshed with streams of running water. The Lyceum, where Aristotle taught, and which, from him, became the seat of the academic school, was situated on the other side of the city, beyond the Ilissus. It was used also as a theatre for gymnastic exercises. Near it was the less famous Cynosarges, where Antisthenes taught, the founder of the Cynic school.

The subsequent sects of Zeno and Epicurus taught within the city. Zeno chose the portico called *Pæcile*, which was embellished with representations of Athenian victories. Epicurus, fond of ease and of rural scenery, was the first who introduced a garden within the walls; and thus enjoyed at once these two species of luxury.

Not only literary, but political, associations conspired to give interest to particular districts of Athens. The hill of Areopagus, where that august assembly pronounced its decisions; the *Prytæneum*, or senate-house; the *Pnyx*, or forum, where the sovereign people of Athens met to deliberate: all these places, without being particularly splendid in themselves, become in the highest degree interesting to us, by the dignity and importance of the events of which they were the theatre.

We have already given a view of the Athenian constitution, as originally established by Solon. This, however, will give a very inadequate idea of the effects produced by that system, when called into action. The popular branch, as we already observed, was not long of acquiring an ascendancy, far beyond what he had either foreseen or intended. To this cause may be attributed, at once, her prosperity, and the evils with which it was chequered. The activity, the emulation, the free scope to talents of every description, which were excited and afforded by a government so completely popular, were doubtless the grand causes which raised Athens to such a height of glory. The multitude of great men in every department, who followed each other in splendid succession, even to her last decline, is altogether unexampled. This constitution also combined with her military power, in rendering her the head of the popular interest in Greece, and thus necessarily secured the attachment of a majority of the members of every Grecian community. Thus she often conquered by her institutions, as much as by her arms; and was enabled, after conquering, to hold states in easy subjection. We have had sufficient occasion to observe those errors in foreign policy, into which the same constitution precipitated her; her rashness in engaging in enterprises above her strength; her levity in changing from one to another; the perpetual jealousy and suspicion which she nourished against her great men,—a jealousy, which her circumstances indeed might perhaps render necessary, but which often prompted her to reject their services at the time when they were most wanted. We have also had occasion to observe that ambitious and unprincipled avidity, which she displayed in her transactions with foreign states, in which the maxim too often was, that every thing was lawful that was for the benefit of Athens. This was a maxim indeed but too prevalent among the ancient republics; yet Sparta seems generally to have maintained a character of equity decidedly superior to that of her rival. Accordingly the most upright among the Athenians, Aristides, Cimon, and Phocion, generally favoured the party of Sparta and aristocracy. On the other hand, the Athenians are more celebrated for humanity: Their treatment of slaves was milder than in other Grecian states; and the few instances of atrocity

towards conquered states seem to have been sudden bursts of passion, that were quickly followed by repentance.

In their internal economy, the energies of a free government were also, as we shall presently see, powerfully displayed in a career of science and art, the splendour of which has no parallel in the history of nations. At the same time it was productive also of a complication of disorders. The free states of antiquity differed from those of modern times, in not being representative governments. The popular assembly was composed of the whole body of the nation; which not only produced a disorderly multitude, but took away all check of responsibility, such as exists now between the electors and the elected. The people were absolutely despotic, and exercised their power often as arbitrarily and as capriciously as the most worthless individual. As most of the manual labour was performed by slaves, such of the free citizens as had no inheritance, that is, the greater part of them, were in a state of extreme necessity. When therefore they found, that the public revenue, as well as the property of private individuals, was at their disposal, they soon discovered, and were taught by their flatterers, that these resources might be turned to their private accommodation. This was gradually done more and more, every new courtier endeavouring to outstrip his predecessor. Theatrical amusements, of the utmost splendour, were afforded at the public expense; and a law was at length passed, making it capital to propose any other use of the funds appropriated to them. In the same manner, baths, places of meeting, and other accommodations, of more than royal magnificence, were supplied to the lowest of the people. Trials were decided by a species of jury, the members of which were called Dicasts, and received a small sum (three oboli, equal to fourpence) for the exercise of their office. To be on juries became thus a regular source of subsistence to the poorer classes; hence sprung innumerable abuses. The number of jurymen was raised to 500; that of courts, which sat daily, to ten. Every disposition was shewn, both to multiply trials, and to protract their duration. Accusations were willingly received; and so little was the security, even to the best citizens, of a favourable issue, that Socrates could give no better advice, than to repel them by a counter accusation. The greatest men of the state paid the most humble court to these dicasts. The comic poet introduces one of them saying: "The principal men of the commonwealth attend our levee in the morning. Presently one of those who have embezzled public money approaches, makes a low bow, and begs my favour. 'If ever,' says he, 'you yourself, in any office, or even in the management of a military mess, cheated your comrades, pity me.' He stood trembling before me, as if I had been a god." With the same view of accommodating the people, holidays, the sacrifices at which were distributed among them, were multiplied, till they filled nearly a sixth of the year.

While the revenue of the state was thus employed, rather for private than public wants, the question came to be, how the latter were to be supplied. With this view, the people cast their eyes on the rich, whom they were never disposed to regard very favourably. Was a frigate to be equipped; they pitched upon the man who appeared best able to afford it, and compelled him to do it at his own expense. The same system was adopted with regard to all other branches of public service. The

only remedy which remained was of the most irregular nature. The man, on whom this burden was laid, could call upon any other, whom he thought better able to bear it, either to do the service, or to make a complete exchange of property with himself. Upon the whole, Mr Mitford, who certainly shews no partiality to the Athenian government, hesitates not to declare, that the security of property in it was less than in the most arbitrary of the oriental governments.

Having thus surveyed the political character of Athens, we shall now take a brief view of that which she displayed in arts and letters. The first foundations of her fame in this department were laid under the family of Pisistratus. They shewed themselves zealous patrons of learning; and Pisistratus himself is said to have been the first who collected together the scattered fragments of the Iliad and Odyssey. The grand efforts of Athenian genius, however, were subsequent to this æra; it continued to blaze uninterruptedly during the whole period of her political greatness, and even for a short time survived its extinction. The departments in which she chiefly excelled, and to which, indeed, she gave birth, seem to have been those connected with human manners and passions—the drama, moral and political philosophy, and history.

To Athens the drama was indebted, at once, for its first origin and its highest perfection. Yet her first essays were of the rudest description. At certain seasons of the year, festivals were celebrated in honour of Bacchus; and, on these occasions, it was customary for the peasants to mount their cars, and sing extemporary verses in honour of that deity. On some, who displayed, in this exercise, peculiar powers of amusing the public, rustic rewards, a cask of wine, or a goat, were bestowed; hence arose the expressions, *tragædia*, *tragædia*, the song of the cask, the song of the goat. These persons wore masks, a custom always retained on the Greek theatre; and, as they gradually improved, and dialogue was added, the exhibitions approached more and more to the nature of regular dramas. Athens now becoming a city of some magnitude and opulence, a demand arose in it for similar amusements, and persons were not wanting to gratify this taste. The division into comedy and tragedy had now been established. The first year before the establishment of the tyranny of Pisistratus, Susarion mounted a scaffold, and performed a sort of comedy, or satirical dialogue. About thirty years after, Thespis, from a waggon, exhibited the first tragedy on record. Before his time there had been nothing but the chorus; he added a single actor. Tragedy, though posterior in its origin to comedy, was soonest carried to perfection. Thespis was succeeded by Cratinas, in whose time the scaffolding, similar probably to that used in our puppet-shows, on which the exhibition was performed, having accidentally broke down, the Athenians applied themselves to build a secure and more elegant theatre. Phrynichus, his successor, perfected tragedy still more, by substituting the iambic verse for the trochaic, which had been employed as suited to the accompaniment of dancing, once an essential part of theatrical entertainments. The spectacles were now addressed to the fancy more than to the senses. Immediately after him, and about the period of the Persian war, arose Eschylus, who carried Grecian tragedy to the summit of perfection. His pieces are characterized by a fierce and terrible sublimity, congenial to his own character, and that of his age, which were wholly devoted to military glory. He was

succeeded by Sophocles, who, born in a milder and more polished age, exhibited different characters. Inferior in energy and sublimity, he still combined a large portion of these qualities with more skilful texture of plot, and greater powers of pathos. Immediately following, and for a long time contemporary, was Euripides, who excelled both his predecessors in pathetic powers, in which, among the ancients at least, he stands unrivalled; and who cultivated also a sententious morality unknown to his predecessors. In other respects, however, he is inferior to Æschylus and Sophocles.

With him tragedy, after a short reign, expired; but comedy had only now attained its perfection, and continued to flourish during successive ages. It assumed different aspects, according to the different periods of its existence. These are called the Old, the Middle, and the New Comedy.

The old comedy was cultivated by Eupolis, Cratinus, and Aristophanes. It employed itself in the most bitter, and often indecent satire, upon distinguished persons in the commonwealth, who were introduced by name upon the stage, and held up to public derision. The writings of Aristophanes alone have come down to us, and display a very powerful, but coarse vein of humour. After him, Alexis and Antiphanes introduced the middle comedy. The object of this was still satire, but the improved taste of the age, and the preponderating influence of the Macedonian government, no longer allowed the writers to indulge in personal attacks; it was therefore directed against manners in general. All the writers of this school, of whom Mr. Cumberland has enumerated thirty-two, have perished, leaving only a few fragments, which make us regret the more what we have lost. The middle was followed by the new comedy, more cultivated, polished, and regular, than either of its predecessors, and nearly approaching, it would appear, to what we call sentimental comedy. It seems to have been chiefly occupied by love-plots, tender sentiments, and more delicate satire. Upwards of 200 names have been transmitted to us, of those who shone in this line of composition; but their names only, not their works, if we except a few scattered fragments, chiefly handed down by fathers of the church, and which therefore have a serious, and even gloomy colouring, probably very different from the general strain of these dramas. Menander, Philemon, and Diphilus, are the most celebrated of these writers.

The drama of Athens, however, is not more celebrated than its schools of philosophy. As every citizen might acquire an influence in the management of public affairs, provided he possessed the requisite qualifications, it became a desirable object to attain those talents, and above all that eloquence, which might enable him to sway the decisions of a popular assembly. A class of teachers then arose, by whom this was publicly professed; but the greater number of these, deserting their legitimate office, taught only the art of making subtle distinctions, and defending right and wrong indiscriminately. These went by the name of Sophists, which originally signified merely wise men, but which, from their misconduct, has long become odious. The abuses of this sect were exposed, and their fame eclipsed, by Socrates, the most celebrated of all heathen philosophers, for pure morality and practical wisdom. His instructions were entirely oral, and seem to have consisted chiefly in the application of sound sense and virtuous principle to the varied scenes of public and private life, of which he was a con-

stant spectator. Openly attacking the pernicious doctrines of the sophist, and secretly despising the superstitions of the multitude, he excited hostility in both; and at length his unworthy fate became as much the shame, as his life had been the glory, of Athens. When death, however, had silenced envy, his fame broke forth in full lustre; and a crowd of votaries arose, who trod, or affected to tread, in his footsteps. Each, however, modifying and explaining the Socratic doctrines as suited his own peculiar views, many branches, widely differing from each other, sprung from the same root. Xenophon, the most judicious and most amiable of his disciples, seems to have transmitted his doctrine the most pure and uncorrupted. Plato, on the contrary, sought to elevate and adorn it by an admixture both with his own lofty, and often visionary ideas, and with the tenets of other schools. Hence he may be considered rather as having founded a system of his own, than as having faithfully transmitted to us that of his master. Amid a variety of subordinate sects, we may then distinguish the two opposite, at the head of which were Diogenes the cynic, and Aristippus the philosopher of pleasure. The former placed wisdom entirely in the absence of all refinement, and often even of common decency, and in a life marked only by austerity and privation. The other, conceiving man made only for enjoyment, sought it wherever it was to be found; and hence became a welcome guest in courts, and in all gay and opulent societies. These two were succeeded by the still more celebrated sects of Zeno and Epicurus, of which the former placed the supreme good in virtue, the other in pleasure alone, and which long continued to divide the ancient world. The leading doctrines of each are well known, and shall be fully explained in their proper place.

We may observe, that each of these moral systems was, in general, accompanied by a physical system, professing to account for all the grand phenomena of the universe. This last, however, being founded commonly on very imperfect and inaccurate observation, was of little comparative value. It would seem, on the whole, that no branch, either of physical or mathematical science, was much indebted to Athens. Living nature was there too varied and interesting, to leave much room for attention to its dead and inanimate portions.

Where political events were so varied and important, the art of recording them was not likely to be neglected. Although Athens cannot boast of having produced the father of history, yet the most eminent of his successors sprung up in her bosom. Thucydides has left us a history of cotemporary events, free from all those partialities to which such a narrative might be supposed liable. His performance is a model of sound judgment, attic precision, and grave and severe eloquence. His successor Xenophon was, still more than he, versant in real life and in public affairs. His style, less nervous, is more simple, sweet, and flowing. In his *Anabasis*, and in his *Grecian history* (a continuation of that of Thucydides,) his fidelity is equally unimpeached; but in the *Cyropædia*, his refined moral taste has led him to wander into the regions of fiction, in order to delineate a more perfect model than real life could afford. With him expired the historic muse of Athens.

Amid these higher pursuits, Athens was not less busily, nor less successfully occupied in cultivating those arts, which relate to the beauty of external form. Painting and sculpture originated indeed, not there, but in

the fertile and earlier civilized regions of Ionia, and the islands of the Ægean Sea. It was in Athens, however, and under the auspices of Pericles, that these arts attained their highest perfection. The fame of Phidias and Praxiteles as sculptors, of Zeuxis and Parrhasius as painters, is still unrivalled in their respective departments. All these indeed were not born in Athens, but it was there that their talents were chiefly formed and exerted. With the masterpieces of these artists Pericles lavishly adorned the public buildings and temples of Athens, and thus gratified at once the taste and vanity of his countrymen. All the works of Grecian painting have been swallowed up by time; but the ruins of Athens present remains of sculpture and architecture, which still astonish the world. The termination of Athenian liberty involved also that of the fine arts; in the age of Alexander, the school of Sicily had already attained the pre-eminence.

The political superiority of Athens ceased after the battle of Cheronea; yet gleams of her ancient spirit still occasionally broke forth. The death of Philip, which occurred soon after, appeared to present a favourable opportunity of throwing off the yoke; and it was embraced at once by Athens, by Thebes, and by the tribes of Thrace and Illyricum. But the young hero, having crushed his barbarous enemies, returned with the rapidity of lightning into Greece. Thebes suffered a dreadful punishment for her daring attempt; and a similar fate seemed to impend over Athens. With a magnanimity, however, worthy of her best days, she braved the prohibition issued by the conqueror against giving shelter to the exiles from Thebes. Yet Alexander, notwithstanding this additional provocation, consulted his fame, by extending clemency to so renowned a city.

During the victorious career of Alexander, Athens remained without any movement, even while Sparta, under the command of Agis, was making a vigorous, though unsuccessful, attempt at emancipation. A remnant of independence, however, appeared, by her deciding in favour of Demosthenes, the celebrated contest concerning the crown, (See DEMOSTHENES,) though she banished him two years afterwards, on a somewhat doubtful accusation of bribery. Alexander appears always to have shewn a peculiar favour to this city. Devoted to the pursuit of glory, he viewed Athens as the dispenser of it. The speech is well known which he made in passing the Hydaspes: "What dangers am I encountering, O Athenians, in order to be praised by you!" The decree, however, which he passed for the restoration of all the Grecian exiles to their respective cities, though humanity, as well as policy, might have prompted it, excited high indignation among a people so torn by party contests; and when it was immediately followed by the news of his death, the popular party easily gained the ascendancy. Demosthenes, restored to his country, became again the soul of the Athenian councils. A confederacy was formed, with Athens at its head; and a numerous army was raised, to make head against that under the command of Antipater. Leosthenes, being appointed general, attacked the Macedonian commander, defeated and drove him into Lamia, a town of Thessaly, to which he immediately laid siege. Leosthenes fell before the town; but his successor Antiphrilos routed a body of troops which had advanced to relieve it. Alarmed by these checks, Craterus hastened over with a band of those veterans who had conquered under Alexander. This was too hard a trial for the Athenian levies;

they were vanquished; and at this single disaster, the whole confederacy fell immediately to pieces. Antipater marched directly to Athens, which submitted without resistance. Demosthenes was the victim of this revolution. Having fled to the island of Calauria, and taken refuge in a temple, he was surrounded by Macedonian officers, and, to save himself from falling into their hands, swallowed poison. Phocion, who had always resisted this rash ebullition, now sought in vain to save Athens from the ignominy of a Macedonian garrison. Twelve thousand citizens were disfranchised; the popular form of government was suppressed; and every measure was taken to hold her in the most strict and absolute subjection.

Thus Athens lost all that remained of her liberty; and she became from this period, as distinguished for the meanness of her adulation, as she had formerly been for the fierceness of her independence. Never did people run into such excesses of flattery. Every successive master who was imposed upon them, from the moment that he came into power, was fawned upon with the same abject servility. Antipater, on his death-bed, left the government of Macedon to Polysperchon, who acting in every respect contrary to his predecessor, espoused the popular interest among the states of Greece, and particularly in Athens. Phocion, who had been attached to Antipater and the opposite interest, became then the object of hostility to the new governor, who procured from the Athenians his condemnation and death. Thus Athens lost her last great man, in the same manner as she had lost so many of his predecessors.

Polysperchon was not long of being driven out by Cassander, the son of Antipater, who re-established the old system, and set Demetrius Phalerus at the head of the government. The choice was excellent; and under this accomplished person Athens enjoyed more quiet, and perhaps more real happiness, than during the days of her glory. Every species of honour was profusely lavished on him: insomuch, that while Miltiades, the deliverer of the state, was honoured only by a place in an historical painting, three hundred and sixty statues were decreed to Demetrius Phalerus. Yet when, after a sway of twelve years, he was dispossessed by Demetrius, the son of Antigonus, these statues were instantly thrown down, and all their adulation transferred to this new master. Demetrius here abandoned himself to every species of debauchery; and the Athenians dishonoured themselves completely by their servile compliance even with his most shameful propensities. Yet when, fortune changing, he soon afterwards sought refuge in their city, he found the gates shut against him. By another turn of affairs, he soon after became again master of the city, and, according to every appearance, the Athenians had to dread the severest effects of his vengeance. But Demetrius, an accomplished person, and ambitious of fame, sought rather to attach them by an ostentatious clemency. Yet when adverse fortune compelled him once more to seek refuge within her walls, he failed not to experience a second repulse.

Athens now, amid the struggle of contending potentates, enjoyed, for some time, a precarious independence. This, such as it was, seems to have infused a portion of her ancient spirit. An inundation of Gauls, under the command of Brennus, poured down upon Greece, which they prepared to enter by the straits of Thermopylæ. The Athenians took the lead in the confederacy of Grecian states formed to oppose them; and Brennus,

after a desperate effort, found the barbarous strength of his troops insufficient to contend with the superior skill and valour of the Greeks. He was forced to relinquish his enterprize, and to content himself with laying waste the northern districts.

This last glimmering, however, of her ancient glory, was quickly extinguished. Antigonus, the son of Demetrius, having ascended the throne of Macedon, determined to avenge on Athens the injuries of his father: he laid siege to it therefore with a powerful army; and, notwithstanding the efforts made by the other states, and even by Ptolemy of Egypt, he at length succeeded in compelling it to receive a Macedonian garrison.

The Achaian republic now began its splendid career; during the whole of which Athens remained in inglorious tranquillity. In the wars, however, which immediately succeeded between Rome and Macedon, she makes some small figure. She even gave occasion to the second Macedonian war. Two Acarnanian youths had been put to death by the Athenians, for some venial offence committed at their sacred rites. The Acarnanians, having in vain demanded satisfaction, obtained permission from Philip to lay waste Attica, in which they were aided by some Macedonian troops. The Athenians, without making any attempt to defend themselves, appealed to the Romans, who, eager for a pretence to make war upon Philip, availed themselves of this event. Attalus and the Rhodian ambassadors, then in alliance with Rome, happening to pass near Athens, appeared in the city, and were received with the most extravagant honours.

Athens, however, took little share in the war which she had kindled, but derived a precarious security from the hostility of contending powers. The form of liberty was for a time confirmed to her, by that decree which gave freedom to all the Grecian states. But when Rome, having reduced Macedon to subjection, no longer kept terms with the other states, Athens, along with them, was reduced into a province, under the title of Achaia. She does not even appear to have shared in the gallant resistance made by the Achaian republic. What followed, however, some time after, shewed, that there was still some remnant of her ancient spirit. Mithridates, the renowned enemy of Rome, had openly raised the standard against that power, and had commenced hostilities by an indiscriminate massacre of all the Romans who were settled in Asia. From that moment, Athens hailed him as her deliverer. Rome, distracted by faction, was supposed to be in no condition to enforce her dominion. The complete triumph, however, of Sylla over Marius, fatally deceived this expectation. The former general marched directly into Greece, inflamed with the most furious thirst of vengeance. All the states submitted, except Athens; and therefore against it the Roman general advanced without delay. Athens made a resistance beyond expectation, and not unworthy of her ancient fame. The city and the Piræus, which formed separate fortresses, were then in different hands. The former was commanded by Aristion, who is represented as a violent and profligate character, but who appears evidently to have possessed great energy and activity. The Piræus was held by Archelaus, an officer of Mithridates, possessed of distinguished merit and ability. Sylla spared no efforts to overcome this unexpected resistance. To construct his machines, he levelled all the sacred groves around Athens, nor spared even the Academy

and the Lyceum. He plundered the treasures of Delphi, without regard to the sanctity which had so long been attached to them. Yet every attempt which he made to reduce the place by storm was completely baffled, and he was compelled to have recourse to blockade. Having succeeded in demolishing part of the long walls which joined Athens to the Piræus, the city, deprived of communication with its harbour, soon began to be straightened for subsistence. Treachery completed what force had begun; the supplies of Athens were entirely cut off; and she began to experience all the horrors of famine. Aristion desperately resisted every proposal of surrender; but at length the citizens, either through fatigue or disaffection, ceased to keep the same strict watch as formerly. Sylla, observing this, prepared a midnight attack, which, finding them completely unprepared, soon made him master of the city. Exasperated at their long defence, he gave full vent to the ferocity of his character. Not only was the city given up to indiscriminate plunder; but orders were issued, that every Athenian, of every age and sex, should be put to the sword. The city streamed with Athenian blood; and scarcely, of her whole population, did a feeble remnant survive. Archelaus, seeing the city lost, judged it necessary to evacuate the Piræus. Sylla, thus deprived of human victims, vented his impious fury on the structures, the pride of Athens and of Greece, with which that port was adorned. The fairest edifices of the city had been defaced; but the Piræus was completely levelled with the ground.

On the few occasions in which the Athenians took any share in the civil wars of Rome, they were still faithful to the cause of liberty. They espoused the part of Pompey against Cæsar, and again, on the death of Cæsar, they threw down his statues, and in their stead set up those of Brutus and Cassius, which last they placed next to those of Harmodius and Aristogiton. After the battle of Philippi, when there remained no longer any party friendly to liberty, Athens, in the division of the empire between Octavius and Antony, fell to the share of the latter. The profuse and thoughtless gaiety of his character seems even to have conciliated the affections of the people. After his last departure from Rome, he fixed his residence for some time among them, and was received with all that servile flattery which they were accustomed to lavish on the favourite of the moment. By a refinement of adulation, they proposed his marriage with Minerva, their tutelary deity; to which Antony, with artful waggery, consented, on condition that she should bring him a portion of ten millions of drachmas, (500,000*l.*) Augustus punished this attachment to his rival, by depriving Athens of her few remaining privileges, and of the island of Ægina, which she had received from Antony.

But while Athens thus saw every trace of her political existence vanish, she rose to an empire scarcely less flattering, to which Rome itself was obliged to bow. Her conquerors looked to her as to the teacher and arbiter of philosophy and science. All the most distinguished Roman youth were ambitious of literary accomplishments; and all flocked to Athens, in order to acquire them. Several even preferred its tranquil and elegant pleasures to the tumult of the capital; and among these was Atticus, the celebrated friend of Cicero, who received that surname from having fixed his residence at Athens.

The tyranny of the twelve Cæsars, being exercised

chiefly against the nobles and senators of Rome, did not fall very heavy on this, or the other cities of Greece. Germanicus, under Tiberius's reign, bestowed on it the valued privilege of having a licitor to precede the magistrates. Even Nero conferred a nominal liberty upon it, along with the rest of Greece; and it is remarkable, that this gift was revoked by Vespasian. But it was in the golden age of the Roman empire, that Athens was destined to resume, in regard to outward appearance at least, her former splendour. Adrian, that singular character, ambitious to perpetuate his name by monuments of art, chose Athens as his favourite residence, and lavished treasures in adorning it. He built several temples, and, above all, he finished that of Jupiter Olympius, the work of successive kings, and one of the greatest productions of human art. He founded a splendid library. He bestowed also many municipal and other privileges. The Athenians repaid his benefits with their accustomed profusion of gratitude. An inscription, placed on one of the gates, declared Athens to be no longer the city of Theseus, but of Adrian.

The Antonines trod in the footsteps of Adrian. Under them, Herodes Atticus devoted an immense fortune to the embellishment of the city, and the promotion of learning. He was at the head of a species of university, founded by Adrian, and the professors of which were increased by Marcus Aurelius to thirteen. There were two for each of the four sects of philosophy, two rhetoricians, two civilians, and a president. Handsome salaries were attached to these appointments.

Amid the accumulated calamities of the Roman empire, the taste for learning and the arts suffered a gradual decline. Yet to those, who still cherished it, Athens continued to be the centre of resort. Being shut out, however, from all concerns of business, or of public life, her teachers lost entirely that sound and manly character, which they once possessed, and sunk into mere pedants and sophists. A sort of mystic fraternity seems to have been formed, admission into which was gained by a variety of childish ceremonies; while the initiated were distinguished by a peculiar dress, in which no one else was allowed to appear. Clokes and staves, a long beard, and a book in the left hand, were every where to be seen; and all the walks were full of parties engaged in argument.

Athens was also distinguished as the last retreat of paganism. Philosophy, which had formerly been rather hostile to superstition, proved now its only support. Her pride had never brooked the humility and the absence of worldly wisdom, which characterised that divine dispensation. Instead of acknowledging the purity of its doctrines and precepts, she employed a preposterous ingenuity in drawing a veil over the deformities of the pagan mythology. It was at Athens that Julian was supposed to have imbibed that enmity against Christianity which distinguished his reign. As, however, the ancient religion more and more declined, the credit of Athens declined along with it. Under the succeeding emperors, she experienced the most mortifying neglect, and at length her schools were entirely shut by Justinian.

It was not, however, merely in the decline of learning, and of the ancient religion, that Athens felt the calamities of the Roman world. Already, in the first invasion of the Goths, in the middle of the third century, Athens was selected as a victim. The fleet of those barbarians anchored in the Piræus. Attempts

had been made to repair the walls, which had been allowed to fall into decay. They were unable, however, to resist the impetuous attack of the Goths. Athens was taken, and plundered. Dexippus, meanwhile, a brave officer, having basily collected a body of troops, unexpectedly attacked, and drove them out of the city with considerable loss. It is reported that, during this visit, the Goths, having collected all the libraries of Athens, were preparing to burn them; but one of their number diverted them from the design, by suggesting the propriety of leaving to their enemies what appeared to be the most effectual instrument for cherishing and promoting their unwarlike spirit. Serious doubts, however, are entertained as to the truth of this anecdote.

Greece now enjoyed a long respite from foreign war, till the weak reign of Arcadius and Honorius, when a still more dreadful tempest burst upon her. Alaric, that ferocious and terrible chief, after overrunning the rest of Greece, advanced into Attica, and found Athens defenceless. The whole country was converted into a desert; but it seems uncertain whether he plundered the city, or whether he accepted the greater part of its wealth as a ransom. Certain it is, that it suffered severely; and Synesius, a cotemporary, compares it to the mere skin of a slaughtered victim.

After the devastations of Alaric, and still more, after the shutting of her schools, Athens ceased almost entirely to attract the attention of mankind. The pursuits of industry, however, seem to have been carried on with some activity; Besides the honey of Mount Hymettus, there seems to have been a pretty considerable manufacture of silk; since, in 1139, a colony was transported from Athens to Sicily, with the view of introducing that branch of industry into the latter country.

After the taking of Constantinople by the Latins, in the beginning of the thirteenth century, the western powers began to view Greece as an object of ambition. In the division of the Greek empire which they made among themselves, Macedonia and Greece fell to the share of Boniface, marquis of Montserrat, who bestowed Athens and Thebes on Otho de la Roche, one of his followers. This prince reigned with the title of Duke of Athens, which remained for a considerable time; hence Chaucer and Shakspeare, confounding dates, talk of *Thesus, Duke of Athens*. After several successions, it came by marriage to Walter of Brienne. Considerable opposition, however, seems to have been made to him among his vassals; and these being reinforced by the Catalans, who then extended devastation and conquest over these regions, the new duke was expelled, and forced to return to France, where he fell in the battle of Poitiers. About twenty years after, his son made a fruitless attempt to recover it. Meanwhile the Catalans, having been compelled to acknowledge the supremacy of the house of Arragon, the government of Athens remained for some time at the disposal of that house. It was then seized by the powerful Florentine family of the Acciajoli. One of them ceded it to the Venetians, but his son seized it again, and it remained in the family till 1455, when it surrendered to Omar, a general of Mahomet II, and thus formed one of the two hundred cities which that prince took from the Christians. He settled a colony in it, and incorporated it completely with the Turkish empire.

Since that time, Athens is known in history only by two ineffectual attempts of the Venetians to make them-

selves masters of it. The first was in 1464, under their general Victor Capella. They gained possession both of the Piræus and of the city; but, failing in their attempt upon the Acropolis, were obliged to retire. The next was in 1687. In this siege, the Turks having made the Parthenon their powder magazine, a bomb fell into it, and blew up the whole roof of that famous edifice. Athens surrendered; but the very next year, the Venetians were forced to abandon it.

It would be impossible to conclude, without endeavouring to give some idea of what Athens now is, and of what still remains to her after such a series of destroying revolutions. Even after all that time and barbarism have effected, her ruins still excite astonishment and admiration in every beholder. We shall be the better enabled to satisfy the curiosity of our readers, as, besides the latest printed accounts, we have had access to oral information still more recent, and of the highest authenticity.

In this survey, we naturally turn our eyes first to the Acropolis, of which a considerable portion is still standing. It has been converted by the Turks into a fortress, and a large irregular wall built round it. In this there appear some remains of the old wall, with fragments of columns, which have been taken from the ruins for the purpose of building it. Of the Propylea, which formed the ancient entrance, the right wing was a temple of Victory. The roof of this edifice remained till 1656, when it was carried away by a sudden explosion. On its columns the Turks have constructed a battery of cannon. In a part of the wall still remaining are some fragments of exquisite sculpture in bas relief, representing the combat of the Athenians with the Amazons. Of the opposite wing of the Propylea, there still remain six columns, with gateways between them. These columns are of marble, white as snow, and of the finest architecture. Each is not, though it appears to be composed of a single piece, but of three or four joined so skilfully, that, though exposed to the weather for two thousand years no separation has taken place. These columns are half covered by a wall, which the Turks have raised in front of them.

From the Propylea, we enter into the Parthenon, that grand display of Athenian magnificence. Eight columns of the eastern front, and several of the lateral porticos, are still standing. Of the frontispiece, which represented the contest of Neptune and Minerva for Athens, nothing remains, but the head of a sea horse, and the figures of two women, whose heads are wanting; but these slender specimens display admirable truth and beauty. The combat of the Centaurs and the Læpithæ is in better preservation. Of all the statues with which it was enriched, that of Adrian alone remains. The inside is now converted into a mosque. Upon the whole, this edifice, mutilated as it is, retains still an air of inexpressible grandeur.

There are considerable remains also of the Erechtheum, particularly those beautiful female figures, called Caryatides, which support, instead of columns, two of the porticos.

Of the two theatres, there remains only so much of the outer walls, as is sufficient to shew their site, and their immense magnitude. The area is now ploughed, and produces corn.

Having thus surveyed the Acropolis, we shall now enter within the town, which does not, however, present

any monuments of equal magnitude. Near a church called Great St Mary, are three exquisite Corinthian columns, supporting an architrave. This passed originally for the temple of Jupiter Olympius; an idea which Stuart has clearly proved to be erroneous. He supposes it to be a remnant of the *Pæcile*.

The Tower of the Winds, by Andronicus Cyrrhestes, is still entire. Its figure is octagon, and on each of the sides is carved, in relief, a representation of one of the principal winds. The sculpture is admirable. This building owes its preservation to its having become the mosque of an order of Dervises.

Among the monuments of distinguished men, of which a street called the Tripods was almost entirely composed, one only remains, the choragic monument of Lysicrates. It consists of a basement, circular colonade, and cupola. The order is Corinthian. The architect and sculpture are exquisite. It was supposed by Wheeler to be the Lantern of Demosthenes, where that orator retired to study; but this is clearly refuted by Stuart.

Of the splendid Gymnasium erected by Ptolemy, a few black and ruined walls present the only traces.

On going without the city, our attention is immediately attracted by the sublime ruins of the temple of Jupiter Olympius. Sixteen columns only remain, of one hundred and twenty. Wheeler, in 1676, found seventeen; but a little before Chandler's visit in 1765, one had been overturned for the building of a mosque. Of the statues, which, in such numbers, enriched this edifice, none now remain. Some only of the pedestals and inscriptions are found scattered in different quarters, and often half buried in the earth.

The temple of Theseus is still nearly entire, except the roof, which is modern. The sculptures on the outside are almost entirely defaced, but those which adorn the friezes on the inside are in better preservation. They represent the exploits of that hero. His combat with a Centaur is particularly distinguished.

Of places which derive their interest from the scenes which were acted in them, considerable remains may also be observed. In the hill of Arcopagus, where sat that famous tribunal, we may still discover the steps cut in the rock, by which it was ascended; the seats of the judges; and, opposite to them, those of the accuser and accused. This hill is now a burying-place for the Turks, and is covered with their tombs.

The *Pnyx*, or place for the assembly of the people, which lies near the Arcopagus, is still nearly in its original condition. In it are still seen the pulpit for the orators cut out in the rock; the seats of the secretaries, who drew up the decrees; and, in the two angles, those of the officers, who imposed silence, and published the result of the public deliberations. Niches are also seen, where were placed the offerings of those who obtained from the people either favour or acquittal. Awful sensations are inspired by the view of this once grand and busy scene, whence issued those schemes, which changed so often the face of the ancient world.

We may still trace the area of the *Stadium*, built by Herodes Atticus entirely of white marble, and on which the Athenian youth were employed in those gymnastic exercises so much valued by the Greeks. The site of the *Lyceum* is discoverable by a number of loose stones scattered about. A modern house and garden now cover the site of the *Academy*. Within its precincts the walks of the Peripatetics may yet be traced; and many olive trees remain, of a most venerable antiquity.

The long walls are entirely demolished; but their foundations may still be traced under the shrubs which cover the plain. The Piræus, another Athens, retains scarcely a memorial of its ancient greatness. Only a few scattered fragments of columns are found in it, as well as in the two neighbouring harbours of Munychia and Phalerum. A few small craft now frequent this famed port, for the accommodation of which there is a paltry custom-house.

Athens contains now from eight to ten thousand inhabitants, one-fourth of whom are Turks, and the rest Greeks. The latter enjoy a milder lot than in most other places subject to Turkish dominion. They have had recourse to an expedient not very honourable, that of chusing for their protector the Kiskar Aga, or chief of the black eunuchs, to whom they pay a tribute of thirty thousand crowns. They have been known also to rise and inflict bloody vengeance on their oppressors. They are distinguished both by address, and by a spirit of liberty, rarely now observable among their countrymen. Even some forms of their ancient constitution are still preserved. Chandler, on entering Athens, was met by an *archon*. The Turks have here abated somewhat of their usual lordliness and austerity, and mixed more intimately with the subject people.

The Greeks have an archbishop, who enjoys a tolerable revenue; and no less than two hundred places of worship.

By far the most recent and accurate survey of Athens is that made by lord Elgin, during his embassy at Constantinople. The detailed result will, we trust, in some form or other, be given to the public; in the mean time, the following notice may be interesting:

Even before leaving England, Lord Elgin had understood, that the most acceptable service which he could render to the arts, would be to procure *casts* of the most interesting remains of sculpture and architecture, which still existed in Athens. But the expense of engaging artists from this country was too great for an individual to undertake, and an application for assistance from government proved ineffectual. In Sicily, however, where he touched on his passage to Constantinople, he was more fortunate: To the most eminent artist of that island, the troubled state of Italy enabled him to add others, of very uncommon abilities, from Rome. In this manner he engaged six artists; one general painter, one figure painter, two *formatori* for the making of the casts, and two architects. With these Lord Elgin, after much difficulty, obtained from the Turkish government permission to proceed to Athens. They spent three years there, mutually assisting and controuling the operations of each other, and taking measurements and representations of every object which seemed deserving of attention.

The measurements have been made in the utmost detail, and with extreme care and minuteness. From

the rough drafts, plans, elevations, and finished drawings of the most remarkable objects have been executed. In these, all the sculpture has been restored, with uncommon taste and ability. The bas-reliefs, besides, or the different temples, have been drawn, with perfect accuracy, in their present state of mutilation and decay. Most of these bas-reliefs, and all the characteristic architectural features in the different monuments now remaining at Athens, have been moulded; and the casts and moulds being conveyed to London, are now in the lordship's possession. Picturesque views of Athens, as well as various parts of Greece, have been taken by one of the most eminent painters of Europe.

Besides these models and representations, Lord Elgin collected also numerous pieces of Athenian sculpture in statues, reliefs, capitals, cornices, friezes, &c. The advantages which he possessed enabled him to accumulate a greater collection of these than exists elsewhere in Europe. In making this collection, he was strongly animated by seeing the destruction into which these remains were sinking, through the influence of Turkish barbarism. Some statues in the *posticum* of the Parthenon had been pounded down for mortar, on account of their affording the whitest marble within reach; and this mortar was employed in the construction of miserable huts. Even without any such object, the Turks were in the habit of climbing up the walls, and amusing themselves with defacing the precious remains of sculpture with which they were adorned. We have already seen the disaster which befel the Parthenon, in consequence of its being converted into a powder magazine; yet this had not prevented the Turks from turning the *Erechtheum* to the same use. One temple, which Stuart found in tolerable preservation, had, since his time, been destroyed so completely, that his Lordship could with difficulty distinguish where it had stood.

By these operations, Lord Elgin has, as it were, transported Athens to London, and has formed a school of Grecian art, to which there does not, at present, exist a parallel.

All the histories of Greece treat copiously of Athens; both ancient, as Herodotus, Thucydides, Xenophon; and modern, as Rollin, Gillies, Mitford, &c. See Xenophon *de Republica Atheniensium*. A number of elaborate tracts by Meursius, *de Regibus Atticis*, *de Fortuna Attica*, *de Republica Atheniensium*, &c.; all which Gronovius has inserted in his *Thesaurus*. Young's *History of Athens*. Drummond *on the Government of Athens*. The modern state of Athens was described, in 1676, by Wheeler and Spon; and, more recently, in 1765, by Chandler, in his *Travels in Greece*. Messrs Stuart and Revett, who travelled about the same time with the last, have published the *Ruins of Athens*, with magnificent plates. The most recent account is by Scrofanì, a Sicilian, of whose accuracy, however, we entertain serious doubts. (p)

ATHERINA, a genus of fishes belonging to the order of Abdominales, in the division of bony fishes. See ICHTHYOLOGY. (f)

ATHERSTONE, a market-town in the parish of Mancetter, in Warwickshire. There is here a manufactory of hats, ribbands, and shaloons, and the cotton trade has been lately introduced. Number of houses 546. Population 2650, of whom 748 are employed in trade. Distance from Warwick 23 miles. (j)

ATHINI, the modern name of Athens.*

ATHLETÆ, among the ancients, persons who were trained to feats of strength and agility. In times when

* Ἀθῆναι, corrupted from Ἀθῆναι, the ancient name of that celebrated city. The Abbé Lenglet du Fresnoy, and most of the French Geographers call it *Setines*, which they pretend to be the modern name given to it by the Romæic Greeks. Even M. de Voltaire has adopted this mistake, the origin of which is not uninteresting to those who are curious of tracing the means by which the names of cities become gradually altered and corrupted. It is most probable that some French travellers, little conversant in the Greek language, hearing the natives of the country say that they were going to *Athens*, εἰς or εἰς Ἀθῆνας, and for shortness' sake εἰς Ἀθῆνας, have conceived the preposition thus prefixed to the proper name to be a part of it, and returned home with the information that Athens was now called *Satine* or *Setines*. In the same manner it appears that *Scambol* or *Istambol*, the Turkish name of Constantinople, has been formed from εἰς τὴν πόλιν, *to the city*; for the Greeks at this day generally leave out the long name of the founder of their capital, and call it simply πόλις, the city, which the Turks, who, it is well known, cannot utter the letter *h*, pronounce *boli*, and in a still shorter way *bol*, or *bull*. Thus from εἰς τὴν πόλιν, they have made *Is-ten-bol*, which we write *Istambol*, or *Stamboul*.

If these derivations should appear fanciful to the American readers, they need only recollect what happens every day in our own city, when vessels are so frequently advertised to sail for the port of *Aux Cayes*. Every body knows that by this denomination is meant the town of *Les Cayes*, in the island of St. Domingo, and that *Aux Cayes* is the dative case, which is sufficiently expressed in English by the preposition *to*. Thus "I am going to *Aux Cayes*," speaking of a French town, is precisely the same thing as I am going to εἰς Ἀθῆνας, or, "to εἰς τὴν πόλιν, speaking of a city of Greece. In both instances the dative case is improperly used instead of the nominative.

While upon this subject, it may not be amiss to take notice of another curious corruption of the name of a Greek island. We mean ancient *Eubœa*, now called *Negropont*, as well as the straits which separates it from the continent, and which was formerly called *Euripus*. It seems that, at some period which cannot now be ascertained, the ancient name of *Eubœa* fell into disuse, and the island and the straits, were called by the same name, *Εὐβοίος*, which has been since corrupted into *Βορβο*, and *Εγρίβο*, which latter name is now given to it by the modern Greeks. But the Venetians, by adding the letter *N* at the beginning, substituting *e* for *i* in the middle, and putting an Italian termination at the end, have made it *Negroponte*, which name is now generally adopted by the Christian nations of Europe. DE RONCEAU.

national safety depended more on muscular exertion, than on the delicate management of warlike machines, vigour and activity of body were the qualities of chief consideration. Accordingly, in those stages of society denominated savage, the greatest hero is generally the most robust individual; and the breadth of his breast, the magnitude of his limbs, and the swiftness of his career, are, in the songs of the bards, no less the topics of panegyric, than are his martial achievements. Hence arose, in different countries, independently of the love of pastime, various customs and institutions, tending to the development of the bodily powers. The Greeks surpassed all nations in their attention to this circumstance; for, though the Romans had also, in the days of their simplicity, their racers and wrestlers, they forsook, in process of time, these harmless and manly sports, for the inhuman exhibition of gladiatorial combats, and the fights of wild beasts.

The athletic exercises of the Greeks were all originally subservient to the formation of the soldier, and calculated to produce a race of men alike distinguished for symmetry of form, hardness of constitution, and corporeal power. We will not take it upon us to say, that the Greeks were, in these respects, the very first in the world; but whether we judge from the form and attitude of the Grecian figure, as displayed in the ancient statues, or from the tremendous onset of the Grecian warrior in the day of battle, we are equally entitled to draw the conclusion, that this system of exercises was not without its effect.

These sports were for a long time practised by the people, without the aid of professional instruction: but a little before the age of Plato, they assumed a scientific appearance, when regular professors started up, who made it their exclusive business to practise the athletic arts. The excessive encouragement bestowed on these masters was only in proportion to the value attached by the Greeks to their employment. Excellence in this department was the chief ambition of the youth, as it opened for them a passage to the first of mortal honours; for not only was a conqueror in the Olympic games in many cases supported in splendour during the remainder of his life; but he received an honorary crown; his name was immortalized in public songs; statues were erected to his memory; his victory was an æra in the annals of his country; and, in the earlier periods, was sometimes worshipped as a god. For these reasons, the athletic arts were ranked by the Greeks among those denominated liberal. It was long the ambition of kings and princes to excel in them; and no pains or expenses were spared for the possible attainment of such high distinction. But after the institution of regular establishments for these exercises, the original intention was soon forgotten. Maintained in luxury at the public expense, and therefore not very respectable for their morals, the athletæ degenerated into mere prize-fighters; their arts, hitherto accounted liberal, and ranked among the noblest accomplishments, gradually suffered in the general estimation; and their habits of body and mind, instead of promoting the military character, rendered them much inferior, in that respect, to the ordinary citizens. Thus, by mistaking the means for the end, the Greeks in a great measure defeated the purpose of the institution: for, though the games were now carried to much greater perfection, and were still accessible to as many as inclined; yet they necessarily became, at last, more a matter of exhibition than of

practice; since few could hope to succeed, or wish to embark, in a contest with regular bullies. The training and habits now acquired, were not those of men qualified for enduring every privation, and every species of exertion in the field; but of performing idle feats in one situation at home.

During the best periods of Greece, all the youth were regularly trained to the exercises of the palæstra. In every town there was a gymnasium, or school, for these and other branches of juvenile education, supported at the public charge, and furnished with baths, courts, race-grounds, and every other convenience. To these seminaries, the youth repaired at a very early period; for we find, that even in the great games, at which all Greece appeared, boys of 12 years of age obtained prizes. The discipline to which these were subjected, would naturally be suited to their tender age; but those who were more advanced, and, particularly, who intended to signalize themselves at any of the public exhibitions, underwent a course of training, admirably well calculated for the sinewy contest. This preparation, which sometimes occupied a space of ten months, was extremely rigorous; and, being prescribed by law, was indispensable. The outlines of it are given by Horace:

Qui studet optatam cursu contingere metam,
Multa tulit fecitque puer; sudavit et alsit,
Abstinnit Venere et Baccho.

Epictetus also, in the following passage, takes notice of the preparatory discipline. "You must conform to rule, eat against your will, abstain from dainties: you must necessarily be exercised at the appointed hour, in heat and in cold; you must drink no cold water, and sometimes no wine. In short, you must give yourself up to the superintendent as to a physician, and then turn out to the contest. Here it is not unfrequent to dislocate an arm, to sprain an ancle, to swallow a quantity of dust, to be flogged into the bargain, and after all to be vanquished.

The diet of the professed *athletæ*, in Italy as well as Greece, was strictly attended to. In the more early ages, they were fed on new cheese, dried figs, and boiled grain. At length, one Pythagoras, the master of a gymnasium, introduced the use of animal food, having observed that it gave more firmness and body to the muscles. Pork, either roasted or broiled, was the favourite dish for this purpose; and was found of so nutritious a quality, according to Galen, that the *athletæ* who intermitted the use of it but for one day, were sensible the next of a material diminution of their vigour. Their breakfast consisted of a little dry bread, which was always unleavened: and their principal meal, which was after their exercises, consisted principally of animal food; and this, on some occasions, they were forced to devour in prodigious quantities. As a dry diet was considered of essential importance to the strength and solidity of the muscular system, their drink, consisting of warm water, or of a thick luscious kind of wine, was administered in very sparing quantities. The method of feeding, however, admitted of considerable variations, adapted to the particular case of the pupil; for, as a racer and a boxer required different qualifications, so also the whole of their regimen was somewhat different.

The *athletæ* were allowed as much sleep as they chose, since this was thought conducive to that rotun-

dity of body which they deemed so necessary. In the morning they went occasionally into the cold bath, for the purpose of bracing their sinews: and, after their exercises were over, they were immersed in a tepid bath, where they were carefully scrubbed with the stry-gil: they were then dried with towels, and anointed with oil. After this, they took their principal meal, and engaged in no more exercise that day.

Their medical treatment was simple, though rather peculiar. Glysters were sometimes administered, when the appetite seemed to flag: but the favourite remedy for this was an emetic, which was thought to be less debilitating than cathartics. The finger or a feather served, by tickling the fauces, to excite vomiting. Sexual intercourse was strictly prohibited, as peculiarly detrimental to strength; and plates of lead were applied at night to the groins, to repress improper affections. Their backs, too, were occasionally scourged, till the blood flowed: this was intended both for habituating the patient to bear the acutest pain, and as an antidote against plethora, to which these men were peculiarly liable.

The *athletæ* were daily exercised, for many hours, in every species of exertion; and, to the eternal reproach of Grecian delicacy, in a state of complete nudity. There were, indeed, female *athletæ*, and these, according to all accounts, were decently dressed, and contended in classes by themselves; though, if we may believe Ovid, both these formalities were dispensed with in ancient Sparta. Paris writes thus to Helen:

More tuæ gentis nitidâ dum nuda palæstra
Ludis: et es nudis fœmina mista viris.

The male champions originally wore a small scarf round the middle, which, in after times, was laid aside as an incumbrance: there are some authors, however, who deny this, and assert, that the covering was always retained, except perhaps in the case of wrestling. The excellence of the Grecian sculpture has been attributed, and probably with justice, to these naked exhibitions, where every muscle and sinew was displayed in every possible variety of action. But what was this advantage, when compared with the horrid effects which we know to have been produced on the minds and on the conduct of the spectators?

The exercises to which these men were trained were of the most laborious and hardy description. It is not our intention here to enter into a detail of all the amusements and arrangements practised in the ancient shows; this will be done with more propriety under some other title, as *GLADIATOR*, *OLYMPIC GAMES*, &c. We shall here, therefore, restrict ourselves to a short account of those exercises properly denominated athletic, and which were not only practised in every gymnasium, but exhibited in public, on innumerable occasions, in every town and district of Greece. These then consisted of the following kinds:

1st, *Leaping*.—Those who contended in this ancient sport had weights attached to their bodies, to give a greater momentum to their exertion, and to swing them forward. The weight was sometimes attached to the head, or shoulders, but generally carried in the hand, when it had holes for the admission of the fingers. We are not informed that height was aimed at in the leap, which was directed to a hole, or ditch, in the ground; and into this it was sometimes the grand object to alight.

2d, The *Foot-Race*.—Swiftness of foot was one of the most enviable qualities in the eyes of the ancients. Homer uniformly ascribes it to his great hero Achilles, and elsewhere praises it as one of the most valuable endowments of nature :

No greater glory can be e'er attain'd,
Than what strong hands or nimble feet have gain'd.

David praises Saul and Jonathan on the same principle : " they were swifter than eagles." Those who professed this sport had short buskins, or sandals, to protect their feet ; and they sometimes ran in complete armour. They are said to have found means to contract, by the actual cautery, the size of the spleen, which was deemed an impediment to velocity. The perfection to which some of the champions attained in this game, is described by the Greek bards with the most poetical extravagance. In an epigram in the *Anthologia*, the racer is feigned to have become invisible from his excessive swiftness, and to have only reappeared when he halted at the end of his course.

3d, *Darting*.—The instrument generally employed here was a javelin, or pole. These were discharged sometimes from the naked hand, and sometimes with the help of a thong tied about the middle of the weapon. This exercise also included archery, and perhaps slinging.

4th, *Quoiting*, or throwing the *Disc*.—Here the instrument was a heavy mass of stone, brass, or iron. It was taken up in one hand, between the thumb and fingers ; was thrown under the arm like our common quoit ; and being, in general, exceedingly smooth, and convex on both sides, was grasped and retained with considerable difficulty. In this game, as in our *putting-stone*, there was but one disc to a company ; and the contest was, not as in our quoits, who should hit a particular object, but who should throw to the greatest distance.

5th, *Wrestling*.—Previously to this exercise, which was carried to the utmost perfection by the Greeks, the naked combatants were rubbed all over with oil, or with a composition called *ceroma*, consisting of oil, wax, and dust. This, while it secured the skin, by making it soft and pliant, and also prevented excessive perspiration, occasioned, at the same time, a degree of lubricity, which greatly increased the difficulty and the variety of the contest. To correct, however, in some degree this inconvenience, the champions rolled themselves in the dust of the *palæstra*. When they were people of condition, they used odoriferous unguents instead of oil, and were sprinkled with a fine sand, or dry earth, brought from Egypt and Italy. In wrestling, every stratagem was allowed for throwing down the antagonist : such as tripping up his heels, twining round his limbs, and squeezing his ribs together ; but kicking and boxing were strictly prohibited. A victory was obtained by giving three falls ; but if, in falling, the vanquished drew down his opponent along with him, the contest was either begun anew, or continued on the ground, when he who got uppermost was the conqueror.

6th, The *Pentathlon*.—In addition to the five simple exercises which we have now shortly described, there was another called *five-games*, consisting of all these in close succession, in the order in which they are mentioned in the following line :

Ἄλμα, ποδάκειν, δίσκον, ακοντα, πάλην.

The leap, race, disc, the dart, and wrestling play.

Some authors believe boxing to have been sometimes introduced into the pentathlon, and that this was a name for a series of any five games. This opinion, however, is not generally adopted. As a peculiar course of training was necessary for this game, a pentathlete seldom succeeded in any of the simple contests of which it was composed. It is spoken of by the ancients as being a very tedious and difficult contest.

7th, The *Cæstus*.—The games of which we have hitherto treated were common to all Greece ; but the two *sports* which follow were prohibited by the Lacedæmonians, not, however, on account of their cruelty, but by reason of a condition imposed upon the vanquished, that they must declare themselves worsted. This ignominious confession was deemed inconsistent with the Spartan character. The first of these exercises was what we may term boxing, a game which, in its original state among the Greeks, was, like that practised among ourselves, a contest of bare fists ; but which, by gradual *improvements*, and the introduction of the *cæstus*, assumed an aspect peculiarly frightful. In this advanced stage of the science, the fingers and hand were wound up in thongs of raw bull-hide, which were sometimes continued up to the elbow ; and to this offensive and defensive contrivance were often added pieces of lead or iron ; so that the human hand was thus converted into a species of hammer. In the first edition of Dryden's *Virgil*, there is a print representing the *cæstus* in a different manner ; for there each of the combatants holds by the end a long tapering bag of leather, supposed to be stuffed with lead or iron ; and, with these massy sacks, in the form of a Hercules's club, the heroes are belabouring each other with alternate strokes. The armed glove, however, seems to be the true idea of the *cæstus*, which, when wielded by a brawny arm, must have produced dreadful devastation in the physiognomy of the antagonist. To close up an eye, or derange a little the structure of the nose, were in those days but trifling exploits.—when men got their jaws demolished at a single blow, their ears torn off their heads, and every frontal protuberance converted into a depression. The heroes in this contest, it is true, wore a stiff cap to protect their heads, and were generally swelled, by feeding, to an enormous size, for the purpose of shielding their bones from injury ; but, with all these precautions, they were sadly mangled, as the following lines will testify :

This victor, glorious in his olive wreath,
Had once eyes, eye brows, nose, and ears, and teeth ;
But turning *cæstus champion* to his cost,
These, and (still worse) his heritage he lost :
For by his brother sued, disown'd at last,
Confronted with his picture he was cast.

8th, The *Pancratium*.—This name, which may be literally translated *all-fights*, was applied to a game, compounded, at pleasure, of almost all the possible modes of annoyance which two naked men, without weapons, could exercise towards each other. In this exercise, boxing and wrestling were the most prominent features, accompanied, however, with an infinite number of subordinate varieties, as kicking, elbowing, rolling on the ground, throttling, scratching, and squeezing. In short, the combatants were turned out, in a complete state of nature, only lubricated with oil, to avail themselves freely of all their proper resources, and to exert every joint, muscle, and limb, for the de-

feat of their antagonists. To this great freedom of choice, indeed, there were a very few *humane* exceptions. Thus they were not allowed to put out an eye, as is frequently done in the American pancratium; nor to bite off the flesh, which they pressed between their teeth; nor to strike under the ribs with the ends of their fingers; nor, in short, to kill their adversaries designedly. There was a pancratiast named Sostratus, who was successful near twenty times in the public games. His method, the most humane on record, was this: he always seized the fingers of his antagonist, crushed them into one bloody mass, and thus obliged him to resign the palm! See Hom. *Il.* l. xxiii.; Virg. *Æn.* l. v.; Pausan. l. vi. viii. et passim.; Epict. *Enchir.* c. 29.; Cælius Rhodig. *Ant. Lect.*; Potter's *Antiq. v.* i.; West's *Dissert.*; and Sir John Sinclair's *Code of Health*, v. ii: (E)

ATHLONE, a town of Ireland, situated partly in the county of Westmeath, and partly in the county of Roscommon. It stands on the river Shannon, which separates the counties, over which there is a long bridge with many arches. On the bridge are several ill executed figures and inscriptions, celebrating the success of Queen Elizabeth, and giving an account of the execution of the rebels. Athlone was long the residence of the lord presidents of Connaught, who kept their courts of justice in it. The castle was built by king John, on a round hill like a Danish fort, on the Roscommon side of the river. Notwithstanding the advantageous situation of Athlone for trade, it is still in a poor and ruinous state. W. Long. 7° 49', N. Lat. 53° 21' 30". See Beaufort's *Memoir of a Map of Ireland.* (j)

ATHIOL, a mountainous district in the north of Perthshire in Scotland. See **PERTHSHIRE.** (w)

ATHOR, or **ATHYR**, the name of one of the divinities of the Egyptians, signifying Night, to whom they erected temples. (j)

ATHOS, a mountain of Macedonia, famous in ancient history and poetry. It is situated between the Strymonic and Singitic gulfs, on a mountainous promontory, which is connected with the continent by an isthmus of land about twelve leagues broad. The promontory stretches a great way out into the Ægean Sea, and occasions a long and dangerous circumnavigation. Of the numerous mountains of which this peninsula is composed, Athos proudly towers above all the rest: its conical summit, at times white with snow, is seen by the mariner at the distance of 100 miles; and, though the cold is excessive, it is adorned with plants and trees, chiefly of the fir kind, which climb up its steep sides to a great elevation.

Marvellous stories have been told by the ancients of this celebrated mountain. Unfortunately that portion of Strabo's excellent work is lost, in which he had occasion to describe Athos, and which is poorly supplied by a dry epitome. According to Mela, its height was such as to reach above the clouds. Others have affirmed that it was six miles high, that it soared beyond the regions of rain and tempest, and that ashes, left on its top, continued dry and undisturbed. But the most wonderful story of all is, that of the projection of its shadow, which was reported to extend, at the summer solstice, as far as Lemnos, an island, according to Pliny, 87 miles off, or, according to modern calculation, about 30. It is said that a brazen cow was erected at the termination of the shadow, in the market-place of Myrina, the principal town of Lemnos, with this inscription:

Ἄθων καλοῦσθαι πλεούσαν Λημνιας βοῦς.

i. e. "Athos covers the side of the Lemnian cow." Modern travellers are not agreed about the real height of this mountain. Some make it two miles in perpendicular height; while others reduce its extreme elevation to about 3300 feet. The truth is, that no accurate measurement has yet been made.

Athos, if we may believe the ancient historians, opposed considerable resistance to the power of Xerxes, on his march to Greece. A part of that monarch's fleet having suffered shipwreck off the Athose promontory, he resolved to prevent similar accidents for the future, by cutting a channel through the mountain, sufficient to admit two galleys abreast, each of three banks of oars. By this operation, several cities are said to have been separated from the continent, as Olophyxus, Dion, Thysus, Acrothoon, and Cleone; whence we may conclude that this rugged peninsula was well peopled in ancient times. The Greek writers ascribe the most capricious conduct to the Persian king. Thus, according to these authorities, Xerxes, on making his bridge of boats across the Hellespont, ordered a quantity of fetters to be thrown into the sea, as symbols of the subjection of that stormy element; and on its rebelling against his authority, by throwing his boats into confusion, he rebuked it in an angry speech, which began thus: "Thou salt and bitter water." On the present occasion, the same mad tyrant sent a letter to the mountain, couched in the following language. "Athos, thou proud and aspiring mountain, that liftest up thy head to the skies, I advise thee not to be so audacious as to put rocks and stones in the way of my workmen: if thou opposest me thus, I will cut thee entirely down, and throw thee headlong into the sea." But these accounts can hardly be credited. If Xerxes really made a canal across the isthmus, it must have been much longer than the Greeks reported it. But as no vestiges are now discoverable of so magnificent a work, the whole story has been called in question:

Perforatus Athos, et quicquid Græcia mendax
Audet in historia.

We must not here omit the daring proposal of Stasicrates, an engineer in the service of Alexander, who offered to convert the whole mountain into a statue of that prince. The enormous figure, which must have been in a sitting posture, was to hold a city in his left hand, containing 10,000 inhabitants, and in the right, an immense basin, whence the collected torrents of the mountain should issue in a mighty river. But the project was thought to be too extravagant, even by Alexander.

Mount Athos is now peopled by a numerous horde of Greek monks, denominated Caloyers, who are of the order of St Basil. These devotees, who amount to 6000, fare very hardly, abstaining entirely from flesh, and subsisting chiefly on pickled olives. They were at one time distinguished for their learning, at least for possessing several valuable manuscripts, and for their numerous copies of the Scriptures, to transcribing which they applied themselves with much laudable assiduity. Though now extremely illiterate, so much so that they can scarcely read or write, they have the merit of being sober, peaceable, and industrious; and these qualities have procured for them the good opinion of the Turks, who afford them protection and sustenance. They have

twenty-four monasteries situated on different parts of the mountain, raised in stories to a great height, and surrounded with walls; and these buildings, interspersed with churches, hermitages, and some fortifications, on which are mounted some pieces of artillery, give an extraordinary appearance to this lofty eminence, and present to the eye of the traveller, as he approaches the scene, a most picturesque object, and a pleasing specimen of manual industry. Mount Athos is now called Hagiosoros, or Monte Santo, from the reputed sanctity of its inhabitants. It is in 40° 10' N. Lat. 24° 45' E. Long.

ATHY, a town in the county of Kildare, in Ireland, situated on the river Barrow, which is navigable to the sea. A branch of the great canal from Dublin to the Shannon joins the Barrow at Athy. The exports from the adjacent country to Dublin amount annually to 20,000*l.* and consist of corn, coals, flour, butter, and potatoes. Number of houses 550. Population 3300. W. Long. 7° 1'. N. Lat. 52° 9'. See Beaufort's *Memoir of a Map of Ireland*, and *Anthologia Hibernica*, vol. i. (j)

ATLANTIC OCEAN, the name of that immense tract of sea which separates the western shores of Europe and Africa from the eastern shores of North and South America. An account of Mr Kirwan's theory of the formation of the Atlantic may be seen in the *Transactions of the Royal Irish Academy*, vol. vi. p. 228. (w)

ATLANTIS, an island mentioned in Plato's *Timæus*, as situated beyond the Pillars of Hercules, and surpassing in extent Asia and Africa taken together. Many consider the whole account as an idle fable, not deserving of the least attention. Perizonius, and others, consider it as a proof that the ancients had some obscure knowledge of America; whilst others suppose that it refers to an immense island or continent, formerly existing in the place now occupied by the Atlantic Ocean. We shall lay before our readers an abstract of the original account as given in the *Timæus*, and then shall advert more particularly to the several opinions entertained respecting it. Critias, one of the speakers, professes to have heard the account from his grandfather, who received it from Solon, and this latter learned it from the Egyptian priests, when he studied under them in Egypt. The sum of their accounts is this: that the vast island of Atlantis was situated near the straits of Gades; that it was governed by a race of mighty conquerors, who subdued all Africa as far as Egypt, and all Europe as far as the Tuscan sea. In succeeding ages, however, owing to prodigious earthquakes and inundations, the Atlantic island was suddenly absorbed into the bosom of the ocean, which for many ages afterwards could not be navigated, on account of the numerous rocks and shelves with which it abounded.

There is so much of the marvellous and improbable in this account, that but a moderate share of incredulity is necessary to make us reject the whole as a fable. The information comes to us in a very roundabout way, and from a very suspicious quarter; and it would not be very safe to receive as authentic history, the *ipse dixit* of an Egyptian priest.

There are circumstances, however, which have induced some to think that this Atlantic island is no other than the continent of America. Ammianus Marcellinus

affirms, that the account recorded by Plato is no fable. Crantor also, Plato's first interpreter, considers it as a true history. It is admitted that there is an error in the account, as to the proximity of the island to the Straits of Gibraltar: for Diodorus Siculus informs us, that the Phœnicians in early times, sailing beyond the Pillars of Hercules, were carried by storms and tempests far to the west, till they fell in with a vast island, having navigable rivers and a fruitful soil. It is thought that the Atlantis of Plato, and this island mentioned by Diodorus, can be nothing else than the continent of America; and that the account of the submersion of this vast island arose from the circumstance of its becoming, in course of time, entirely unknown to the ancients.

But many naturalists, among whom are Buffon and Whitehurst, have thought it probable, that such an island or continent as that described by Plato actually existed, and that the Canary islands, the Azores, and Teneriffe, are nothing else than the summits of mountains belonging to such an island or continent submerged, and the fragments of an antediluvian world, consumed and shattered by earthquakes and volcanic eruptions. Whitehurst is of opinion, that the Atlantic island of Plato, was probably the portion of land which, stretching from the north of Ireland, extended to the Azores, and from the Azores to the continent of America. He thinks that the Giant's Causeway, and the abrupt cliffs which environ part of the Atlantic ocean, are a sufficient demonstration, that some violent disruption of the earth has taken place in that quarter at some remote period of the world. We shall let him speak for himself on this subject.

"These circumstances render it necessary to observe, that whosoever attentively views and considers these romantic rocks, together with the exterior appearances of that mountainous cliff, will, I presume, soon discover sufficient cause to conclude, that the crater, from whence that melted matter flowed, together with an immense tract of land towards the north, have been absolutely sunk and swallowed up into the earth, at some remote period of time, and became the bottom of the Atlantic ocean; A period indeed much beyond the reach of any historical monument, or even of tradition itself. But though it does not appear, that any human testimony, or record, has been handed down to us concerning such a tremendous event, yet the history of that fatal catastrophe is faithfully recorded in the book of nature, and in language and characters equally intelligible to all nations, and therefore will not admit of a misinterpretation: I mean the range of lofty abrupt cliffs which environs a part of the Atlantic ocean.

These are characters which cannot mislead, or divert our attention from the true cause thereof; and we may further add, as a collateral testimony, that subterraneous fires have frequently burst open the bottom of that ocean in various parts, and have formed new islands of considerable magnitude; and hence it is evident that the same cause still exists, and produces similar effects. I say, the consideration of such disasters, together with that of the causes still subsisting under the bottom of that immense ocean, almost persuade me to conclude, that Ireland was originally a part of the island Atlantis, which, according to Plato's *Timæus*, was totally swallowed up by a prodigious earthquake, in the space of one day and night, with all its inhabitants, and a numerous host of warlike people, who had subdued a con-

siderable part of the known world." See the *Timæus* of Plato. *Un. Hist.* vol. xviii. p. 250. Buffon's *Nat. Hist.* vol. ix. p. 162. Whitehurst's *Inquiry*, p. 258. Maurice's *Hist. of Hindostan*, vol. i. p. 538. (g)

ATLAS, a chain of mountains in the north-west of Africa, called in the Arabic *Jibbel Attilis*, or the *Mountains of Snow*. This chain of mountains is inhabited by the various tribes of Berebbers, and extends from (Jibbel d'Zatute) Ape's Hill on the Mediterranean to Shtuka and Ait Bamaran in Lower Suse, passing at the distance of 30 miles to the east of Morocco, where they are of an immense height, and covered with eternal snow. This part of the range appears in a clear day like a saddle, when seen from Mogodor, a distance of 140 miles, and it is visible at sea to vessels several leagues off the coast. These mountains, though extremely cold in winter, are salubrious and pleasant. The vallies are well cultivated, and the mountains, having the advantage of various climates, abound in excellent fruits, and extensive forests. The contrast between their snowy summits and the rich verdure below, gradually decaying as it approaches the limit of congelation, has a very singular and picturesque appearance. In the part of the great chain which passes by Morocco to the east there are excellent mines of copper, and the branches which traverse the district of Suse produce silver, copper, iron, lead, and sulphur of saltpetre. They have also mines of gold mixed with antimony and lead ore. According to the Moors, there are many quarries of marble granite, and other valuable rocks in this extensive range. The Berebbers, who inhabit the upper regions of Atlas, live from November to February inclusive in excavations in the mountains. See *Pliny*, lib. v. cap. 1; *Strabo*, lib. xvii; *Shaw's Travels in Barbary*, p. 5; *Lempriere's Journey to Morocco*, p. 75; *Chenier's Present State of Morocco*, vol. 1. p. 13; *Pinkerton's Geography*, vol. iii. p. 815; but particularly *Jackson's Account of the Empire of Morocco*, 1809, p. 10. (o)

ATLAS, the name of that joint or vertebra of the neck which is nearest the head. See ANATOMY. (w)

ATMOMETER, ATMIDOMETER, or ATMEDOMETER, from *ατμος*, *vapour*, and *μετρον*, *a measure*, the name given to an instrument for measuring evaporation. An ingenious instrument of this kind has been described by the celebrated professor Richman, in the *Nov. Comment. Petropol.* vol. ii. p. 121. (w)

ATMOSPHERE, that invisible elastic fluid which surrounds the earth, and encloses it on all sides. It received its name from the Greeks, in consequence of the vapours which are continually mixing with it. The ancients considered it as one of the four elements of which all things are composed, and some of them seem to have thought that it enters as a constituent principle into other bodies, or at least that air and other bodies are mutually convertible into each other. (*Lucret.* lib. v. 274.) No experiments on its nature could well be made by the ancients, as they were unprovided with every instrument fitted for such investigations, and unacquainted with the principles upon which their construction depended. But it has occupied a great deal of the attention of modern philosophers, and has given birth to some of the most brilliant discoveries that grace the annals of science. Its weight was first ascertained by Galileo, and applied by Torricelli to explain the rise of water in pumps, and of mercury in barometrical tubes, and by Paschal to the mensuration of the height of mountains. Its elasticity was accurately determined

by Boyle, who may be considered as in some measure the founder of the science of pneumatics. Halley and Newton explained the effects produced on it by moisture. Hooke, Newton, Boyle, Derham, pointed out its relation to light, to sound, and to electricity. Its effect upon combustibles and animals was investigated by Boyle, Hooke, Mayow, Hales, Priestley, Scheele, and Lavoisier. Its constituents were detected and measured by the experiments of Priestley, Scheele, Lavoisier, and Cavendish. The effect of heat on it was determined by Shuckburgh, Dalton, and Gay Lussac. But it would be an endless task to enumerate all the philosophers, who have distinguished themselves by their investigations of the atmosphere, a list which would include almost all the celebrated names of the last century.

From the experiments of Sir George Shuckburgh Evelyn, (*Phil. Trans.* 1777 and 1798.) made with a degree of precision and patient industry, which perhaps have never been surpassed, it appears, that at the temperature of 60°, when the barometer stands at 30 inches, the specific gravity of atmospherical air is 0.001208, that of water being 1.000, or its weight is to that of water as 1 to 828. Hence 100 cubic inches of it under that pressure and at that temperature weigh 30.5 grains: For a cubic inch of pure water at that temperature weighs 252.506 grains, according to experiments of Shuckburgh corrected by Mr Fletcher. (*Nicholson's Journal*, iv. 35.) The result of the experiments of Lefevre Gineau, who was employed by the French government to ascertain the weight of water, in order to fix their standard of weights, was somewhat different. According to him, a cubic inch of water at 60° weighs 252.72 grains troy. The difference may be partly owing to some small error in the allowance of the expansion of water from 40°, the temperature at which his experiments were made, to 60°. At any rate, the known precision, and the excellent apparatus of Sir George Shuckburgh, entitle his result to the preference. Hawksbee's experiments make air 850 times lighter than water, the barometer being at 29.7, and Dr Halley supposed it about 800. But neither of these numbers is to be put in competition with the result of Sir George Shuckburgh given above. The air, when weighed, is supposed to be in its usual state of dryness; when very moist, its specific gravity is diminished. An exact knowledge of the weight of a given bulk of air is of great importance, because it enables us with much facility to ascertain the weight of all other aërial bodies: for it is easy to determine the relative weight of any elastic fluid to that of air.

When heat is applied to atmospherical air, its bulk increases; while cold, on the other hand, diminishes its bulk. As this change in bulk is very considerable, it affects very much the accuracy of all experiments on it. It has therefore been an object with philosophers to determine the precise amount and rate of the change in bulk produced upon air by heat. M. De Luc, Sir George Shuckburgh Evelyn, General Roy, Mr Dalton, and Mr Gay Lussac, are the gentlemen to whom we are indebted for the solution of this problem. In examining the dilatibility of air by heat, it is necessary that no water be in contact with it. For as heat converts water into vapour, this vapour, mixing with the air, would destroy the accuracy of the results, and make the dilatation appear much greater than it really is. According to the experiments of De Luc, air at the

temperature of 55° when heated 1° of Fahrenheit's thermometer, expands $\frac{1}{163}$ part; according to Shuckburgh, the expansion is $\frac{1}{158}$; according to General Roy, it is $\frac{1}{157}$; according to Dalton, it is $\frac{1}{153}$; and according to Gay Lussac, $\frac{1}{150}$. As Dalton and Gay Lussac were at pains to exclude moisture, we may consider their experiments as more accurate than those that preceded them. As to the rate of expansion, General Roy found it a slowly diminishing ratio from 32° to 212° . Mr Dalton found the same thing. But he considers this diminution as apparent only, and not real, and owing to the expansion of mercury not being equable. According to him, water, mercury, and all liquids, expand as the square of the temperature, reckoning from the freezing point of the respective liquid. According to this notion, the expansion of air, (and indeed of all permanently elastic fluids,) is in geometrical progression to equal increments of temperature. The following Table exhibits the rate of expansion of air from 32° to 212° , according to Mr Dalton:

Degrees of Fahrenheit.	Bulk of Air.	Degrees of Dalton's Thermometer.
32°	1000	32
39.3	1017.9	42
47	1036.1	52
55	1054.7	62
63.3	1073.5	72
72	1092.7	82
81	1112.3	92
90.4	1132.2	102
100.1	1152.4	112
110	1173.1	122

The reader will observe, that the expansion of air in the second column of the Table constitutes a geometrical progression, the ratio of which is 1.0179. The third column exhibits the corresponding degrees of a Fahrenheit's thermometer graduated, according to Mr Dalton's notion of the expansion of mercury, according to the square of the temperature. This notion of Dalton must be allowed to be very ingenious. Unfortunately we are not in possession of any mode of ascertaining how far it is correct. It is only supported by analogical reasoning, and cannot well be otherwise in the present state of our knowledge of heat.

Atmospherical air was long considered as a simple elementary body. But it is now known to consist of at least four distinct substances, namely, oxygen, azote, carbonic acid, and aqueous vapour. The first two substances must be considered as its essential constituents, and constitute in fact almost the whole of it. The other two are variable in their proportion, and exist only in minute quantities, which it is difficult to appreciate.

The first knowledge of the composition of the atmosphere must have been after the period of the discovery of oxygen gas by Dr Priestley in 1774. Lavoisier, indeed, in his posthumous works, appears to insinuate a knowledge of it in 1772. But this claim cannot be admitted, as he gives no hint of any such knowledge in his volume of essays published after that period, and as he was entirely unacquainted with oxygen gas when Priestley shewed him the way to prepare it at Paris, about the end of 1774. It is very probable that Lavoisier became acquainted with the composition of atmospherical air not very long after that period; though some years elapsed before he made it known to the public. Whether he preceded Scheele in his knowledge of this important fact, we do not exactly know. But there is no doubt whatever, that Scheele's investigations were carried on without any assistance from abroad, and that it was in consequence of the publication of his *Treatise on Air and Fire*, that the chemical world became acquainted with the nature and composition of atmospherical air. This important work was printed at Upsal in 1777, with an introduction by Bergmann, and translated into English by Dr Foster in 1780. The experiments of Priestley indeed would have warranted the conclusions respecting the composition of atmospherical air drawn by Scheele; but those of Dr Priestley were different and more complicated. In Scheele's first experiments, he estimated the bulk of oxygen gas in air at 30 per cent. But in the year 1779, he published a set of experiments continued for a whole year, in order to ascertain whether the bulk of oxygen in air be constant, or varies with the season of the year. He found it in general remarkably constant, and amounting to 27 per cent. The smallest bulk was 24, and the greatest observed was 30 per cent. Dr Priestley had made similar experiments, and had estimated the bulk of the oxygen at $\frac{1}{5}$ th of the air, or 20 per cent. Mr Lavoisier's experiments, which were very numerous and varied, almost coincided with those of Scheele. He considered air as composed of 27 parts by bulk of oxygen, and 73 of azote. Mr Cavendish's experiments were published in the Philosophical Transactions for 1783. He proved decisively, that the proportion of the azote and oxygen in the atmosphere does not vary; and by a very careful analysis, concluded, that 100 parts of air in bulk are composed of

79.16 azote
20.84 oxygen

100.00

This opinion was not at first acceded to by chemists, misled by the previous conclusions of Scheele and Lavoisier; and it was not till towards the commencement of the 19th century, that the true proportion of these constituents was generally known. The experiments of Berthollet, in Egypt and in Paris, seem to have led the way to it. These were almost immediately confirmed by those of Davy, Beddoes, and many other chemists. At present it is universally admitted, that atmospherical air never varies in its composition; that it is the same in all places, and in all seasons; and that it consists in bulk of

79 azote
21 oxygen

100

proportions almost exactly the same with those originally settled by Mr Cavendish.

Oxygen gas is undoubtedly the most important of the constituents of the atmosphere, and indeed one of the most remarkable substances in nature, and highly worthy of the investigation of the chemist. Dr Priestley, its original discoverer, gave it the name of *dephlogisticated air*, Scheele called it *emphyreal air*, Lavoisier called it at first *highly respirable air*, then *vital air*, and at last *oxygen gas*, because he considered it as the acidifying principle. It possesses the mechanical properties of common air; combustibles burn in it with great brilliancy; and animals can breath it much longer than the same quantity of common air. If the specific gravity of common air be reckoned 1.000, that of oxygen gas, according to the experiments of Kirwan and Lavoisier, is 1.103; according to Davy, 1.127; according to Fourcroy, Vauquelin, and Seguin, 1.087; and according to Allen and Pepys, 1.090. These results do not differ much from each other, except that of Mr Davy. His oxygen was obtained from the black oxide of manganese, and might perhaps contain a little carbonic acid gas. If we exclude his, the average of the other three is 1.093. This may be considered as near the truth as can well be attained. Rating its specific gravity at 1.093, 100 cubic inches of it, at the temperature of 60° when the barometer stands at 30 inches, will weigh 33½ grains troy.

Azotic gas, the other constituent of atmospherical air, is chiefly recognised by its negative qualities. It possesses the mechanical properties of air; it does not support combustion; and no animal can breath it without death. It constitutes the base of nitric acid, and is one of the constituents of ammonia. There is reason to consider it as a compound body, but hitherto chemists have not been able to ascertain its constituents; though several extraordinary phenomena, observed during the decomposition of ammonia by Davy and Berzelius, cannot well be accounted for, without supposing hydrogen to be a constituent of it. It has been supposed a compound of hydrogen and oxygen; but several circumstances militate against this opinion. Mr Davy has been for some time occupied incessantly in attempts to ascertain its composition, but hitherto without success. Till the discovery be made, some of the most interesting parts of chemistry remain involved in impenetrable obscurity. The specific gravity of azotic gas, according to Kirwan, is 0.985, that of air being 1.000; while, according to Lavoisier and Davy, it is 0.978. This last estimate we are disposed to consider as most correct. If so, 100 cubic inches of it, at the temperature of 60° when the barometer stands at 30 inches, weigh 29.83 grains troy.

Reckoning the specific gravity of oxygen gas 1.093, and that of azotic gas 0.978, and supposing atmospherical air to be composed of 79 parts of azote and 21 oxygen by bulk, it follows, that 100 parts of it in weight are composed of

77.43 azote
22.57 oxygen
100.00

Though it has been ascertained, that these two constituents of air never vary in their proportions, yet as the methods of analysing air are very useful in all chemical investigations of gaseous bodies, and have led to many discoveries of importance, it will be proper to

give an account of them here. They consist in the application of various substances to a given bulk of air which have the property of absorbing and removing the oxygen, but which do not act upon the azote. The diminution of bulk gives the quantity of oxygen; the residue that of azote. The apparatus contrived for these experiments, received the name of *eudiometers*, because they were considered at first as measures of the *goodness* of air. For it was supposed that the proportion of oxygen was variable, and that the salubrious or noxious qualities of the air depended upon that proportion. Ingenhousz thought he discovered, that the atmosphere above the sea contained more oxygen than that above the land; hence he accounted for the supposed salubrity of the sea air, which has been highly extolled from the remotest times.

The first eudiometer was applied in consequence of Dr Priestley's discovery, that nitrous gas absorbs the oxygen from common air. When nitrous gas comes in contact with oxygen gas, they immediately combine and form nitric acid; and if the mixture be standing over water, the acid is immediately absorbed by the liquid. Hence the bulk of a mixture of nitrous gas and common air immediately diminishes, and the diminution is proportional to the quantity of oxygen in the air, supposing all other circumstances the same, and of course measures that quantity. Dr Priestley's method was, to let up into a graduated tube 100 measures of air, and then to add 100 measures of nitrous gas. The mixture became yellow, and its bulk diminished. He denoted the goodness of the air by the residual gas. Thus if 114 parts remained, he said that the goodness of the air, by the test of nitrous gas, was 114; of course the smaller the residue, the greater was the goodness of the air. This method did not ascertain the absolute quantity of oxygen. It was soon observed, that even when the air operated upon was absolutely the same, the residue was liable to considerable variation from apparently trifling circumstances. Thus, for example, if the tube was agitated during the mixture, it was observed that the residue was always much less than if no agitation was applied. If the tube was narrow, the residue was always more considerable than if the tube was wide. The purity of the water, too, over which the experiment was made, had considerable influence. Mr Cavendish observed, that if the water was in such a state, that it frothed when agitated as if it had contained soap, then the residue was always less than it otherwise would be.

The apparatus was much improved by Fontana, who regulated the size of the tube and the manner of mixing the gases; hence the instrument is usually known by the name of Fontana's eudiometer. This eudiometer was employed by Ingenhousz, and the variations which he found in the compositions of the atmosphere, were obviously owing to the errors to which it was liable. Mr Cavendish first pointed out the precautions necessary, in order to ensure accuracy when this eudiometer was employed. But before nitrous gas could be used with advantage in the analysis of air, it was necessary to ascertain the proportion of it which combined with a given bulk of oxygen gas. This was first undertaken by Mr Dalton, (*Phil. Mag.* xxiii. 351.) According to him, 21 parts of oxygen gas are capable of uniting either with 36 measures of nitrous gas, or with $2 \times 36 = 72$ measures. Both of these compounds are soluble in water. If the tube in which the mixture is made be

wide, and if agitation be employed, the two gases come at once in contact, so that the oxygen combines with a maximum of nitrous gas. If the tube be narrow, and if no agitation be employed, the oxygen gas combines with a minimum of nitrous gas. In tubes of intermediate bore, the proportion of nitrous gas, which combines with the oxygen, is intermediate between 36 and 72. Hence his rule is to employ a tube of so small a bore, that water can just be poured easily out of it; to put up into this tube the quantity of air to be examined, and then to let up a quantity of nitrous gas equal to about half the bulk of the air; to allow this mixture to remain two or three minutes without any agitation, and then to observe the diminution of bulk. This diminution is to be multiplied by $\frac{2}{3}$ or 0.368. The product is the bulk of the oxygen gas contained in the air examined. Suppose we employ 100 measures of air, and let up 50 measures of nitrous gas, and that the diminution of bulk amounts to 57; then $57 \times 0.368 = 20.976$, or very nearly 21. This indicates, that the 100 measures of air contain 21 measures of oxygen gas. We have tried the method of Dalton very frequently, and have found that when the tube is sufficiently narrow, and the experiment carefully made, the mean error cannot be rated higher than 1 per cent. When the gas examined contains much more oxygen than common air, and above all, when it is almost pure oxygen, the error is greater; so great, indeed, that the method cannot be depended on.

But though Dalton's method is correct, as far as the analysis of atmospherical air is concerned, there can be little doubt that the proportions which he has assigned as the limits in which oxygen gas and nitrous gas combine are incorrect. We have made many trials to ascertain these limits, but never could obtain the proportions given by Mr Dalton. Mr Gay Lussac has lately turned his attention to this subject, and has given a very simple and satisfactory account of the proportions in which the two gases combine, (*Memoirs D'Arcueil*, tom. ii. 233.) In a paper which he published on the combination of gaseous bodies, he shewed, that in all cases they unite either in equal bulks, or one part in bulk of one with two or three parts of another, and in no intermediate proportions. This opinion was obviously founded on a very ingenious hypothesis of Mr Dalton, relative to the way in which substances combine. This led him to examine the combination of oxygen gas and nitrous gas. The result was, that 100 parts of oxygen gas unite either with 200 or with 500 parts of nitrous gas. The first compound constitutes nitric acid, the second nitrous acid. His method of analysing air, founded upon this discovery, is to let up 100 measures of air into a wide vessel, and then to add 100 measures of nitrous gas. In about a minute the absorption is completed. No agitation is to be employed. The fourth part of the diminution gives the oxygen. Suppose the diminution to amount to 84, the fourth of that number, or 21, represents the oxygen in 100 parts of air. On repeating this experiment, we found it pretty exact, provided the diameter of the glass vessel employed be not less than three or four inches. In narrow vessels it is very inaccurate.

The second kind of eudiometer was first proposed by Volta, and hence is usually known by the name of Volta's eudiometer. It consists in mixing 100 parts of the air to be analysed with 100 parts of hydrogen gas in a graduated tube, and passing an electric spark through the mixture. A detonation takes place; the whole of

the oxygen, and part of the hydrogen, being converted into water. This method is very easy, and is susceptible of great precision. From numerous and decisive experiments, it follows, that one part of oxygen combines with two parts of hydrogen, when the experiment is made in this way. It appears, too, that the whole oxygen disappears, provided the quantity of hydrogen present be sufficient. We have only to mix 100 parts of air and 100 parts of hydrogen gas together, detonate the mixture, and observe the diminution of bulk. The third part of that diminution indicates the quantity of oxygen present. Suppose, with the preceding proportions, that the diminution of bulk amounts to 63, the third part of that number, or 21, indicates the quantity of oxygen gas in 100 parts of air. He must be a careless experimenter, that, with this eudiometer, commits an error of 1 per cent. We therefore consider it as one of the best means of determining the proportion of oxygen gas present in any gaseous mixture. It does not answer quite so well when we use it to ascertain the purity of oxygen gas, or of a gas composed chiefly of oxygen; because in that case, the diminution of bulk in the gaseous mixture is so sudden and so great, that a vacuum is formed, and the water over which the experiment is made lets go a portion of air, which mixes with the residue, and makes it appear greater than it otherwise would be, and, of course, diminishes the proportion of oxygen which the gas really contained. This error is diminished if the water has been recently boiled. We cannot state the amount of this error; though we have convinced ourselves that it often exceeds 2 per cent.

Another method of analysing air, is to expose 100 measures of it to a solution of sulphuret of lime, or of sulphate of iron saturated with nitrous gas. The first of these liquids was recommended by De Marti, the second by Mr Davy. They both answer very well; they gradually absorb the whole of the oxygen, and leave the azote: Hence the diminution of bulk gives the oxygen in the air examined. The absorption may be made in a graduated tube, or in a eudiometrical instrument contrived for the purpose by Mr Pepys, and described in the Philosophical Transactions for 1868.

The last method of analysing air which we shall mention, is that of Berthollet. It consists in placing 100 measures of air in contact with a cylinder of phosphorus. This method succeeds very well in warm weather; but it does not answer at all in winter. We have kept a cylinder of phosphorus for a fortnight in contact with air, at a temperature a little above the freezing point, and the air only lost about 3 per cent. of its bulk; but if you bring it near the fire, the phosphorus soon absorbs the whole oxygen. When the thermometer stands at 70°, the absorption is completed in a few hours. You know the completion by the phosphorus ceasing to smoke. The oxygen, by this process, is removed; but as the azote dissolves a portion of the phosphorus, its bulk is a little greater than it ought to be. According to Berthollet, to obtain the true bulk of the residuary azote, you must diminish it by $\frac{1}{3}$ part. This method is not so convenient as the preceding, at least in this country, because it is so tedious; but it is sufficiently accurate.

The third constituent of the atmosphere is carbonic acid gas. Its presence in the atmosphere was recognised as soon as Dr Black had ascertained the cause of the difference between mild and caustic alkalis: For it was known, that a caustic alkali soon becomes mild by

exposure to the air. Dr Black ascertained, that the *mildness* is owing to the absorption of carbonic acid. From the observations of Saussure we learn, that this gas exists in the atmosphere on the summit of Mount Blanc, which is nearly 16,000 feet above the level of the sea; for lime-water soon deposited its lime in the state of carbonate, when exposed upon the summit of that mountain, (Saussure's *Voyages*, iv. 199.) Humboldt found it in a quantity of air brought down by Garnerin from a height of 4280 feet, to which he had ascended in an air balloon, (*Jour. de Phys.* xlvii. 202. It appears therefore, to constitute a part of every portion of the atmosphere to which we have access.

As this acid gas is produced in great quantities by combustion, respiration, fermentation, and many other of the most common processes of nature, one would be disposed to believe, at first view, that its quantity must be constantly increasing. But this does not appear to be the case, it must therefore be decomposed and separated from air as fast as it is formed. It is of so deleterious a nature, that, if it were to accumulate to any extent, it would render air incapable of supporting life. A candle will not burn in air contaminated with one-ninth of carbonic acid gas.

The quantity of this gas in air is small. Many attempts have been made to ascertain it; but the process is so difficult, that absolute precision cannot be looked for. It was long believed that the carbonic acid present in the atmosphere amounted to one *per cent.* Humboldt made many experiments on the subject, and concluded from them, that its bulk varied from one *per cent.* to half a *per cent.* But this determination is certainly excessive. According to the experiments of Mr Dalton, a quantity of air, equal in bulk to 102,400 grains of water, contains a quantity of carbonic acid just capable of saturating 125 grains of lime-water: 70 measures of carbonic acid gas would produce the same effect: Hence he concludes, that the atmosphere contains $\frac{1}{11000}$ th part of its bulk of carbonic acid gas, (*Phil. Mag.* xxiii. 354.) This quantity we consider as rather below the truth. Mr Cavendish has shewn, that lime-water is capable of depriving air completely of carbonic acid gas: Hence a portion would still remain in Mr Dalton's experiment. Perhaps we shall not err far, if we state the bulk of carbonic acid gas in the atmosphere at $\frac{1}{10000}$ th part.

The 4th constituent of the atmosphere is water in the state of vapour. That water forms a constituent part of the atmosphere, has been known in all ages, and indeed is demonstrated by the rain and dew which is continually falling, and by the great quantity of moisture which sulphuric acid, potash, and other bodies, absorb when exposed to the atmosphere. The quantity of moisture in the atmosphere has been observed to vary greatly at different times, and various instruments have been invented to measure that quantity. These instruments are called *hygrometers*. The most ingenious of them are those of Leslie, Saussure, and De Luc.

It was at first supposed, that the water in the atmosphere was still in the state of water, and that it was held in solution in air precisely as salts are dissolved in water. But it has been at last established by satisfactory experiments, that the water in the atmosphere is in the state of vapour. To De Luc, Saussure, and Dalton, we are chiefly indebted for these experiments.

As to the quantity of water which exists in the atmosphere, it depends upon a variety of circumstances, the investigation of which belongs to that branch of sci-

ence called METEOROLOGY; to which, therefore, we refer. Saussure found that a cubic foot of air, saturated with moisture, at 66°, contains about 8 grains tray-saturated with moisture, or $\frac{1}{67}$ th of its weight. Supposing air always saturated with moisture, the quantity always increases with the temperature, because the elasticity of aqueous vapour increases with the temperature. Hence, in cold weather, the quantity of vapour in air is always small; whereas, in warm weather, it is often considerable. In the torrid zone the aqueous vapour in the atmosphere is capable of supporting from 0.6 to 1 inch of mercury. In Britain it is hardly ever capable of supporting 0.6 inch of mercury; but in summer it is often capable of supporting 0.5 inch, while in winter it often does not exceed 0.1 inch. From these facts it follows, that the weight of water present in the atmosphere varies from $\frac{1}{87}$ to $\frac{1}{31}$ of the whole. Mr Dalton supposes, that the medium quantity of vapour held in solution at once in the atmosphere, may amount to $\frac{1}{75}$ th of its bulk.

These four bodies, oxygen, azote, carbonic acid, and vapour, are the only known constituents of the atmosphere. It cannot be doubted, that other bodies are occasionally present in it. The dreadful effects of marshy situations upon the health of the inhabitants, and the fatal rapidity with which certain diseases are propagated, cannot well be accounted for, without supposing that certain substances which produce a deleterious effect on the animal economy, are occasionally present in the atmosphere. But hitherto no method has been discovered of ascertaining the presence of these bodies, and subjecting them to examination. They are too subtle for our apparatus, and altogether escape the cognizance of our senses. It has been ascertained, however, that certain acid fumes, as those of the muriatic acid, nitric acid, and above all, of the oxymuriatic acid, have the property of destroying these miasmata, or at least of preventing them from producing deleterious effects on the animal economy. (c)

Having considered in the preceding paragraphs the dilatation of atmospherical air by heat, and its chemical composition, we shall now proceed to give a brief and general view of its physical properties, reserving the full discussion of the subject to the article PNEUMATICS.

That atmospherical air is a heavy, compressible, and elastic substance, may be proved by many simple and direct experiments. A bladder filled with air is heavier than when it is in its flaccid state. When subjected to compression, it may be made to occupy a smaller space; and when that pressure is removed, its elasticity enables it to resume its original size. Since the air is heavy, the lower strata of the atmosphere are compressed by the weight of the superincumbent mass. The lowest stratum, supporting the weight of almost the whole atmosphere, will be more dense than the rest; and the superior strata will gradually become more rare, in proportion to the weight which they sustain. The air in the higher regions, therefore, will be extremely rare, on account of its elasticity, which is not checked by any superincumbent pressure. If the air were perfectly elastic, it is obvious that there would be no limit to its expansion, and that the whole atmosphere would be dissipated through infinite space. The elasticity of the atmosphere must consequently diminish in a greater ratio than the weight which compresses it, and there must be a certain state of rarity at which its elasticity

ATMOSPHERE.

ceases. Upon the supposition that the rarity of the air is reciprocally proportional to its superincumbent weight, it may be demonstrated, that if the heights in the atmosphere be taken in arithmetical progression, the rarity of the air at these heights will be in geometrical progression, or, what is the same thing, the altitudes in the atmosphere are as the square roots of the corresponding rarities. Hence we have a method of measuring differences of altitude, by ascertaining with the barometer the rarity of the air at two places whose vertical distance is required. A full account of this method will be found under the article **BAROMETER**.

The weight and pressure of the atmosphere may be ascertained by very simple experiments. If we immerse in water a glass tube open at both ends, the water included in the tube will be on the same level with the fluid which surrounds it. When we apply our mouth to the upper end of the tube, and draw out the air, the included water instantly ascends till the weight of the elevated column, added to the elasticity of the remaining air, exactly balances the pressure of the atmosphere on the surrounding fluid. If we now take a long tube, 40 feet long for example, shut at one end, and, having filled it with water, plunge the open end into a vessel of water, the fluid will then descend in the tube till the weight of the column exactly equals the pressure of the atmosphere; for the air is now excluded from the upper part of the tube, and the weight of the column of fluid is the only force which is left to balance the weight of the atmospherical column. By making this experiment, it will be found that the water stands at from 34 to 35 feet above the general level of the surrounding fluid, and therefore the weight of a column of air reaching to the top of the atmosphere is equal to the weight of a column of water, of the same base, with the altitude of 34 feet, or about 21564 $\frac{1}{2}$ pounds on a square foot, or 15 pounds on every square inch. This experiment may be more easily made by using quicksilver instead of water. The quicksilver will rise to the height of 29 inches in the tube, and will thus measure the pressure of the atmosphere. Hence it follows, that the whole atmosphere exerts the same pressure on the surface of the earth, as if the surface of the globe were covered with water to the depth of thirty-four feet, or with quicksilver to the depth of twenty-nine inches. This pressure has been computed at 12,022,560,000,000,000 pounds, or as equivalent to that of a globe of lead 60 miles in diameter; and if we suppose that a man's body exposes a surface of nearly 15 square feet, he will sustain a pressure of 32343 $\frac{3}{4}$ pounds, or 14 $\frac{1}{2}$ tons.

From the changes which take place in the atmosphere, its pressure is liable to very considerable variations. The column of quicksilver which we have shown to be a measure of that pressure, varies from 28 to 31 inches. The cause of these changes, which are yet but imperfectly known, will be considered under the article **METEOROLOGY**.

If the atmosphere were of uniform density, it would be easy to ascertain, with the utmost accuracy, the height to which it extends; for the height of the atmosphere would obviously be to the height of the mercury in the barometer, as the specific gravity of common air is to the specific gravity of mercury. By making the calculation on this supposition, it will be found that the height of the atmosphere is a little more than 5 miles. As the air, however, gradually diminishes in density,

the atmosphere must reach to a much greater distance from the earth than 5 miles. It appears from the duration of twilight, that at the height of 44 $\frac{1}{2}$ miles, the atmosphere is sufficiently dense to intercept the light of the sun, and reflect it to the earth. We are therefore entitled to conclude, that it extends to a much greater height.

When a ray of light enters the atmosphere, it is bent from its course by the same cause which refracts the rays of light when they pass through any dense medium, such as glass or water. The refraction sustained by light at its first entrance into the atmosphere must be very small, from the extreme rarity of the air. The deviation, however, will gradually increase as it penetrates the denser strata, and the ray will describe a path increasing in curvature as it approaches the earth. From this property of the atmosphere, the apparent altitude of the sun, moon, and stars, is greater than their real elevation, and they appear to be raised above the horizon when they are actually below it. The refraction of the atmosphere near the earth's surface is liable to very considerable anomalies. A very extraordinary phenomenon arising from this cause has been described by Mr Vince. The castle of Dover, concealed by the hill which lies between it and Ramsgate, appeared, on the 6th of August 1806, as if it had been brought over and placed on the side of the hill next to Ramsgate. This phenomenon must have arisen from some variation of density in the intermediate air. Phenomena of the same class with the preceding have been illustrated experimentally by the ingenious Dr Wollaston. See *Edinburgh Transactions*, vol. vi. p. 245.; and *Phil. Trans.* 1778, p. 357; 1798.

But while the solar rays traverse the earth's atmosphere, they suffer another change from the resisting medium which they encounter. When the sun, or any of the heavenly bodies, are considerably elevated above the horizon, their light is transmitted to the earth without any perceptible change; but when these bodies are near the horizon, their light must pass through a long tract of air, and is considerably modified before it reaches the eye of the observer. The momentum of the red, or greatest refrangible rays, being greater than the momentum of the violet, or least refrangible rays, the former will force their way through the resisting medium, while the latter will be either reflected or absorbed. A white beam of light, therefore, will be deprived of a portion of its blue rays by its horizontal passage through the atmosphere, and the resulting colour will be either orange or red, according to the quantity of the least refrangible rays that have been stopt in their course. Hence the rich and brilliant hue with which nature is gilded by the setting sun; hence the glowing red which tinges the morning and evening clouds; and hence the sober purple of twilight, which they assume when their ruddy glare is tempered by the reflected azure of the sky.

We have already seen, that the red rays penetrate through the atmosphere, while the blue rays, less able to surmount the resistance which they meet, are reflected or absorbed in their passage. It is to this cause that we must ascribe the colour of the sky, and the bright azure which tinges the mountains of the distant landscape. As we ascend in the atmosphere, the deepness of the blue tinge gradually dies away; and to the aeronaut who has soared above the denser strata, or to the traveller who has ascended the Alps or the Andes, the

sky appears of a deep black, while the blue rays find a ready passage through the attenuated strata of the atmosphere. It is owing to the same cause that the diver, at the bottom of the sea, is surrounded with the red light which has pierced through the superincumbent fluid, and that the blue rays are reflected from the surface of the ocean. Were it not for the reflecting power of the air, and of the clouds which float in the lower regions of the atmosphere, we should be involved in total darkness by the setting of the sun, and every cloud that passes over his disc. It is to the multiplied reflections which the light of the sun suffers in the atmosphere, that we are indebted for the light of the day, when the earth is enveloped with impenetrable clouds. From the same cause arises the sober hue of the morning and evening twilight, which increases as we recede from the equator, till it blesses with perpetual day the inhabitants of the polar regions.

If the earth were at rest, and not influenced by any other body of the system, its own figure, and that of its atmosphere, would be exactly spherical. In consequence of the diurnal motion of the earth, however, the figure of its atmosphere must be spheroidal like itself. "All the atmospheric strata," says La Place, "should take after a time the rotatory motion, common to the body which they surround. For the friction of these strata against each other, and against the surface of the body, should accelerate the slowest motions, and retard the most rapid, till a perfect equality is established among them. In these changes, and generally in all those which the atmosphere undergoes, the sum of the products of the particles of the body, and of its atmosphere, multiplied respectively by the area which their radii vectores projected on the plain of the equator describe round their common centre of gravity, are always equal in equal times.

Supposing then, that by any cause whatever, the atmosphere should contract itself, or that a part should condense itself on the surface of the body, the rotatory motion of the body, and of its atmosphere, would be accelerated, because the radii vectores of the area, described by the particles of the primitive atmosphere becoming smaller, the sum of the product of all the particles, by the corresponding area, could not remain the same, unless the velocity of rotation augments.

At its surface the atmosphere is only retained by its weight, and the form of this surface is such, that the force which results from the centrifugal and attractive forces of the body, is perpendicular to it. The atmosphere is flattened towards the poles, and distended at its equator; but this ellipticity has limits, and in the case where it is the greatest, the proportion of the axis of the pole and the equator is as two to three.

The atmosphere can only extend itself at the equator, to that point where the centrifugal force exactly balances the force of gravity; for it is evident, that beyond this limit the fluid would dissipate itself. Relative to the sun, this point is distant from its centre by the length of the radius of the orbit of a planet, the period of whose revolution is equal to that of the sun's rotation.

The sun's atmosphere then does not extend so far as Mercury, and consequently does not produce the zodiacal light, which appears to extend even to the terrestrial orbit. Besides, this atmosphere, the axis of whose poles should be at least two-thirds of that of the equator, is very far from having the lenticular form which observation assigns to the zodiacal light.

The point where the centrifugal force balances gravity, is so much nearer to the body, in proportion as its rotatory motion is more rapid. Supposing that the atmosphere extends itself as far as this limit, and that afterwards it contracts and condenses itself from the effect of cold at the surface of the body, the rotatory motion would become more and more rapid, and the farthest limit of the atmosphere would approach continually to its centre: it will then abandon successively in the plane of its equator, fluid zones, which will continue to circulate round the body, because their centrifugal force is equal to their gravity. But this equality not existing relative to those particles of the atmosphere, distant from the equator, they will continue to adhere to it. It is probable that the rings of Saturn are similar zones, abandoned by its atmosphere.

If other bodies circulate round that which has been considered, or if it circulates itself round another body, the limit of its atmosphere is that point where its centrifugal force, *plus* the attraction of the extraneous bodies, balances exactly its gravity. Thus the limit of the moon's atmosphere, is the point where the centrifugal force due to its rotatory motion, *plus* the attractive force of the earth, is in equilibrium with the attraction of this satellite. The mass of the moon being $\frac{1}{81}$ of that of the earth, this point is distant from the centre of the moon, about the ninth part of the distance from the moon to the earth. If, at this distance, the primitive atmosphere of the moon had not been deprived of its elasticity, it would have been carried towards the earth, which might have retained it. This is perhaps the cause why this atmosphere is so little perceptible."

The earth's atmosphere must experience similar oscillations to those of the ocean, from the action of the sun and moon. In an atmosphere, however, like ours, which is so much agitated by other causes, the winds and variations in the barometer, which, arising from the same cause, have the same periods as the tides, must be very inconsiderable. The change in the altitude of the mercury in the barometer is only about $\frac{1}{25}$ of an inch at the equator, where it is a maximum: though it is not improbable, that the oscillations of the atmosphere, like those of the ocean, may be increased by local circumstances. "If we consider all the causes," says La Place, "which disturb the equilibrium of the atmosphere; its great mobility arising from its fluidity and elasticity; the influence of heat and cold on its elasticity; the great mass of vapour that it alternately absorbs and deposits; and lastly, the changes which the rotation of the earth produces in the relative velocities of its particles, which for this reason are displaced in the direction of the meridians; we should not be surprised at the inconstancy and variety of its motions, which it would be very difficult to subject to any fixed and certain laws." See ANEMOMETER, ASTRONOMY, BAROMETER, CHEMISTRY, CLIMATE, METEOROLOGY, PNEUMATICS, and THERMOMETER. (v)

ATMOSPHERES of the Sun, Moon, and Planets. See ASTRONOMY.

ATMOSPHERES of Electrical Bodies. See ELECTRICITY.

ATMOSPHERICAL CLOCK, the name of a machine proposed by Dr Brewster for measuring the mean temperature of the atmosphere during any given interval. This machine records every variation of temperature that takes place during a given period, and the result indicated on the dial-plate is the exact average of all

the heights of the mercury in the thermometer. The variations of heat and cold affect the pendulum, which may be either of the tubular or gridiron kind; and which is so constructed as to render sensible in the motion of the clock the alternate contractions and dilatations which it undergoes. This instrument shall be fully described in a subsequent part of the work. (i)

ATNAH, a tribe of Indians, who inhabit that part of the north-west of America, which lies in W. Long. 122°, and N. Lat. 52°. Their language, according to Mr Mackenzie, has no affinity with any other with which he was acquainted. See Mackenzie's *Journal of a Voyage through the North-West Continent of America*, p. 258. (j)

ATOMICAL PHILOSOPHY, that doctrine which professes to explain the origin of all things, by a combination of atoms.

The philosophers, who adopted this doctrine, may be divided into two classes; the theistical, and the atheistical. The first are those who adopted the ancient doctrine concerning atoms, said to have been first taught by Moschus the Phœnician, who, according to Strabo, lived before the Trojan war. This philosopher taught, that all bodies were composed of atoms, uniform in substance, impenetrable, indivisible, eternal; that the different forms and qualities of matter, arose solely from different combinations of these ultimate atoms; in the same manner as all the words of a language are formed by different combinations of the letters of the alphabet. The same body, for instance, becomes hard, or soft, or fluid, not from any alteration in its substance, but merely from a different arrangement of its constituent atoms. In this way they account for all the primary qualities of matter. And with regard to the secondary qualities, such as heat, cold, sweet, bitter, &c. as these are altogether distinct from the figure, situation, and motion of the insensible atoms, they held, that they must be nothing but sensations or passions excited in the mind, though they are commonly mistaken for qualities in bodies without us.

Now all this is not only perfectly harmless, but also very ingenious, with the exception of the eternity of atoms; an error, which it was not to be supposed that any of the ancient philosophers should avoid, who all maintained the eternity of matter in some form or other. With this exception, the doctrine is very little different from that which has been received and improved in modern times, under the name of the *Corpuscular Philosophy*. For Sir Isaac Newton affirms, that matter was at first created in solid, hard, impenetrable, moveable particles; and that out of these result the various forms and qualities of body. Indeed, no doctrine can be more consistent with pure theism, than that of the ancient atomists: for, whilst they denied to the atoms sensation and innate motion, (an error adopted by the later atomists,) there was an absolute necessity for some intelligent power to arrange them into form, so as to produce that order and regularity, which we perceive in the universe.

Some have attempted to give eclat to this philosophy, by making Moschus, the reputed author of it, the same as Moses. This, however, is very improbable. Moses, in his cosmogony, certainly teaches nothing concerning atoms; and there is no evidence nor probability, that he ever wrote or taught any thing on the subject beyond the concise and simple account contained in the Scriptures. It has even been doubted whether the doctrine

is entitled to such high antiquity, as has been ascribed to it. And many have maintained, that it was first broached by Leucippus, Democritus, or Protagoras, many ages after the æra of Moschus. Such as wish to see this point cleared up, may consult Cudworth's *Intellectual System*, where the antiquity of the doctrine is ably maintained; and where it is traced with infinite learning, though with little method, through all its changes and ramifications, till it ended in absolute atheism.

We now proceed to consider the philosophy of the later atomists, which was decidedly atheistical. The author of this system is generally allowed to have been Leucippus, who is said to have been a disciple of Zeno the Eleatic philosopher, who flourished about the 84th Olympiad. According to Zeno, there is only one being, and that being is God. This appears, as far as it can be understood, to be nothing else than the Pantheistic doctrine, so commonly adopted by the ancient philosophers. But the pupil departed so far from the tenets of his master in this respect, that he introduced a system, which excluded the agency of deity altogether, and professed to account for the production of all natural bodies from physical causes. All this is effected by giving to atoms an internal principle of motion, and making them dance together, till at last they produce a world. Observe then the steps, by which this important process is completed. "The universe, which is infinite, is in part a *plenum*, and in part a *vacuum*. The *plenum* contains innumerable corpuscles or atoms of various figures, which, falling into the *vacuum*, struck against each other; and hence arose a variety of curvilinear motions, which continued, till at length atoms of similar forms met together, and bodies were produced. The primary atoms being specifically of equal weight, and not being able, on account of their multitude, to move in circles, the smaller rose to the exterior parts of the *vacuum*, whilst the larger, entangling themselves, formed a spherical shell, which revolved about its centre, and which included within it all kinds of bodies. This central mass was gradually increased by a perpetual accession of particles from the surrounding shell, till at last the earth was formed. In the mean time, the spherical shell was continually supplied with new bodies, which in its revolution is gathered up from without. Of the particles thus collected in the spherical shell, some, in their combination, formed humid masses, which by their circular motion gradually became dry, and were at length ignited, and became stars. The sun was formed in the same manner, in the exterior surface of the shell; and the moon in its interior surface. In this manner the world was formed." Enfield's *Hist. of Phil.*

Democritus adopted the atomical doctrine as new-modelled by Leucippus; and, by the help of a little more ingenuity, extended its reputation, without correcting any of its absurdities. Both these philosophers had retained the gods in their systems, from a regard to their own safety, and in compliance with popular prejudices. But Protagoras, a little bolder, and a little honest, than his predecessors, hesitated not to speak freely on the subject, to deduce from the doctrine its legitimate consequences, and thus fairly to explode the gods from the universe. For this instance of his zeal, he was banished from Athens; and may claim the honour of being the protomartyr of atheism.

At length appeared Epicurus, who so far outdid the labours of all who had gone before him, in enlarging

and enforcing the atomical doctrine, that his warm admirer Lucretius claims for him the honour of the whole invention. The poet appears particularly grateful for the emancipation of the human mind from the influence of religion, which was completely effected according to the system of his master :

Humana ante oculos fedè cum vita jaceret
In terris oppressâ gravi sub religione,
Primum Graius homo mortales tollere contra
Est oculos ausus.

Epicurus adopted the doctrines of the ancient atomists, to explain the organization and qualities of bodies ; and in so far as he adheres to their principles, he advances many ingenious things in his speculations. But he deserts the path of true science, and of sober thinking, when he attempts to account for the production of all things without the operation of an intelligent cause. According to him, atoms are the elements, from which all things are compounded, and into which they are ultimately resolved. Not only are they the materials, out of which bodies are made ; but that energy or principle of motion, which essentially belongs to them, is the sole agent in all the operations of nature. Having assumed this principle, he then proceeds to show, that all the changes in the figure and properties of bodies consist in local motion. Heat is the influx of certain small, round corpuscles, which insinuate themselves into the pores of bodies in continual succession, till by their perpetual action, the parts are separated, and at length the body dissolved. Cold is the influx of certain irregular atoms, whose motion is slower than those which occasion heat. Production and dissolution are nothing more than a change of the position of atoms, or an increase or diminution of the particles of which bodies are composed.

But the original formation of the world is the principal thing to be accounted for ; and this Epicurus, with most other cosmogonists, makes a very easy process. Accordingly he tells us, without any hesitation, and without the semblance of proof, that a finite number of atoms, tumbling through the *vacuum*, were, in consequence of their innate motion, collected into one indigested mass. A small difficulty, however, occurs here ; if these atoms fell perpendicularly, how did they ever happen to unite ? They could not overtake each other : for in a *vacuum* all bodies fall with equal velocity, whatever may be the difference of their specific gravity in other circumstances. The same objection holds, supposing them to fall obliquely : neither will it do to say that they fell tumultuously, in all different directions : because the principle of gravity, with which they are supposed to be endued, must act uniformly ; and if there be any deflection of the atoms from one regular course, it must proceed from some external cause, which is altogether contrary to Epicurus's system, which ascribes every thing to the energy and activity of atoms. These difficulties were not unobserved ; but they were easily obviated, so long as hypothesis could be substituted for argument. Accordingly, an expedient was devised, to remove these objections : and it was asserted, that the atoms suffered a slight deflection in their course, at different times and different places, by which means they effected a junction. At the same time, this deflection was so small, as not to constitute obliquity ; for Lucretius loudly protests against such heresy as this, and declares it to be contrary to common sense, that bodies should descend by their own weight, in an oblique direction. Nevertheless, to an-

swer his purpose, he is forced to assign to the atoms a declination from the perpendicular descent, whilst he denies that this declination can constitute oblique motion. They may understand this who can. This, however, is a favourite mode of solving difficulties with Epicurus. For, when talking of the form of the gods (another knotty subject) he maintains, that they have *non corpus, sed quasi corpus* ; *non sanguinem, sed quasi sanguinem*, (Cic. de nat. Deor. l. i.) ; so, with regard to the primordial atoms, he seems to say, that they have *non clinamen, sed quasi clinamen*. With respect to these mysteries, we can for once cordially adopt the sentiments of an Epicurean ; *hæc et inventa sunt acutius, et dicta subtilius ab Epicuro, quam ut quisvis ea fossit agnoscere*.

Passing over these few obstacles in the outset, let us suppose the atoms brought together, by whatever means, so as to form a chaos. Then, according to Epicurus, those atoms which were lightest mounted up, and formed the air, the heavens, and the stars ; whilst the more sluggish subsided, and formed the earth in which we live. Thus, these atoms are the handiest things in the world : at one time they descend necessarily, by the power of gravity, to form a chaos ; and they obey no less readily the necessity of the system-maker, and mount at the word of command to form the lights of heaven.

But it surely cannot be necessary to pursue this nonsense farther, nor to attempt a serious refutation of what carries in its face such glaring absurdity. The radical error of Epicurus, and of many others of the ancient philosophers, consisted in supposing motion to be essential to matter, and matter to be eternal. No fact in physical science is better ascertained, than the absolute *inertia* of matter, and its indifference as to motion or rest ; and it is an axiom of natural philosophy, that matter will continue for ever in an uniform state of motion or rest, unless affected by external causes. Were motion essential to matter, we could not conceive matter to exist without it. Abstract from matter any of its general allowed properties, such as solidity, extension, divisibility, &c. and you destroy the idea of it altogether : for it is impossible to form a conception of substance without these qualities. But abstract motion from it, and your conception of it will be as complete as ever. It is expected the reader will distinguish between motion and mobility, the latter being one of the general properties of matter. And, with regard to the opinion that matter is eternal, though it was adopted by all the ancients, and also by some among the moderns, yet we have no hesitation in affirming that it is equally ill-founded with that which we have been refuting. For if matter is eternal, then it is also self-existent, infinite, and immutable, and excludes the very possibility of Deity, which even an atheist would scarcely venture to affirm. It is evident, however, that there cannot be two different substances in existence, each of them eternal, self-existent, independent, and unchangeable. Whether then shall we acknowledge as the eternal principle, matter, which is motionless, inert, and incapable of acting with intelligence, or that spirit which we denominate God, and which can be demonstrated to be possessed of power, intelligence, and goodness ? The question scarcely requires an answer. There can be only one eternal Being, and that Being is God, from whom matter receives its existence, motions, forms, and modifications. For a fuller demonstration of this subject, see Cadworth's *Intellect. Syst.* and the articles MATTER, METAPHYSICS, MOTION. (g)

ATONEMENT, in theology, means that sacrifice which Christ offered in his own person for the sins of men. This doctrine supposes the human race to be in a fallen state, and incapable of effecting its deliverance. There is evidently the strongest foundation in reason for this representation. It is perfectly obvious that all have sinned; and, if we may judge from the infinitely varied and inconsistent attempts of men, it appears no less certain that they were altogether incapable of devising any effectual method of expiating their sins. The austere-ities of the bigot, however, the self-inflicted torments of the enthusiast, and the sacrificial rites of all nations, show the general impression on the human mind, that some expiation was necessary. The whole tenor of the sacred scriptures leads to the same conclusion. The Supreme Lawgiver could not but exact perfect obedience to his laws, and denounce punishment against those who transgress them: for laws cannot be enforced but by penal sanctions, and these sanctions can have no effect unless they are carried into execution. According to this view of the case, then, the whole human race must stand condemned by the pure and holy law of God, which they have so often violated. It is absurd to talk of the mercy of God interposing to save us from punishment, without any satisfaction to his justice; it would be the same as if a king were to enact wholesome laws for the security of his people, which his clemency prevented him from ever carrying into execution. Thus, then, the justice and holiness of God stood in the way of an unconditional pardon, and demanded that the purity of his nature should be vindicated, and the honour of his law asserted; he could not however have inflicted on man the punishment which his sins deserved, without involving the whole human race in one common ruin, as he formerly did with the generation before the flood. In order, then, that the sinner might be justified, and the honour of the divine law preserved inviolate, God sent his Son into the world, with his own free consent, that he might take away sin by the sacrifice of himself. For this purpose he assumed the human nature, that he might exhibit a perfect example of righteousness, and accommodate his instructions to our capacities; but chiefly that he might suffer and die for our offences.

The adversaries of this doctrine have endeavoured to bring it into discredit, by representing it as a-kin to the notions of the heathens, who conceived their gods to be cruel, and vindictive, and only to be appeased by the blood of innocent victims. No representation can be more contrary to the spirit of Scripture, which uniformly represents the Almighty as actuated by love, and not by vengeance, when he planned the great scheme of redemption. "God so loved the world, that he gave his only begotten Son, that whosoever believeth on him might not perish, but have everlasting life:" and to show that his displeasure was directed against the offence, rather than the offenders, he punished sin in the person of his own Son, "making him to be sin for us, though he knew no sin, that we might be the righteousness of God in him."

It has been disputed whether the divinity of Christ be essentially connected with the doctrine of his atonement. All the Arians maintain the negative side of the question: they admit the efficacy of the atonement, but deny the proper divinity of Christ. Some Trinitarians are of the same opinion, maintaining that the efficacy of the atonement arises from its being appointed by God, and not from the dignity of the sufferer. But if this

were the case, we do not see why the blood of bul- and of rams might not have been equally meritorious, for they certainly were offered by divine appointment. Besides, there is an axiom equally applicable to physics, to morals, and to theology; *Frustra fit per plura, quod fieri potest per pauciora*. This axiom has been formed, from contemplating the works and dispensations of God; in which, whilst there is nothing defective, we never discover any thing superfluous, or redundant. Admitting, then, the divinity of Christ, we cannot well see how any one can deny it to be essentially connected with the efficacy of his atonement: for if a divine person has suffered, and that by God's appointment, we may conclude, from the general analogy of nature, that it is, not only proper it should be so, but that nothing less could have sufficed. This conclusion is also in perfect consistence with the usual sentiments of mankind on this subject, who have uniformly believed that sacrifices were efficacious, in proportion to their value. This sentiment, with certain qualifications, is strictly true; and we would therefore naturally conclude, that the sacrifice of the Son of God, as being most valuable in its nature, was, on that account, most effectual in its consequences for expiating the sins of men. The apostle, indeed, seems to decide this question, and to show that the prevailing efficacy of our High Priest depends on his supreme dignity; and that nothing less could have suited the wants of men. "Such a High Priest became us, who is holy, harmless, undefiled, separate from sinners, and made higher than the heavens." Heb. vii. 26.

The further exposition of the doctrine of atonement, with the various opinions entertained respecting it, belongs more properly to the article THEOLOGY: we shall therefore content ourselves at present, with obviating some of the principal objections which have been urged against the general doctrine.

Deists, who reject the whole of revelation, reject of course the doctrine of atonement. In this they are at least consistent, which is more than can be said for the Socinians, who join them in this respect, whilst they pretend to reverence the scriptures as a revelation from heaven: their objections are the same, in so far as they pretend to draw them from reason: the Socinians have a separate contest to maintain, when they attempt to reconcile their opinions with the declarations of scripture. In the first place, it is a favourite argument with both, that no atonement is necessary, because repentance is sufficient to procure forgiveness: this they say is demonstrable on principles of reason; which we positively deny. Before the necessity of repentance was so strongly insisted on in the gospel, very little stress seems to have been laid on this quality; we will do the heathen moralists the justice to say, that they were, in general, men of too good sense to maintain this unreasonable and dangerous doctrine, that repentance was a sufficient reparation for offences. This would indeed have made sin sit very light on the conscience, when the perpetrator knew that a little sorrow would absolve him from guilt; and the argument drawn from such an opinion, would apply with equal force against the infliction of civil punishment, as against an atonement for crimes. The repentance of a criminal is never admitted by the laws of any country as a sufficient compensation for guilt; nor does the criminal himself regard it in this light; but whilst he expresses his sorrow for the offence, confesses at the same time the justice of his pun-

ishment. This favourite doctrine then of Deists and Socinians, as to the independent efficacy of repentance, seems to have no foundation, either in the practice or in the conscience of men. Nor does it receive any countenance from the general analogy of nature, or the usual course of the divine dispensations. Even in the ordinary affairs of life, when men neglect their duty, or give themselves up to intemperance, we frequently observe, that repentance and reformation cannot save them from the natural consequences of their guilt or neglect; but the ruin of their affairs and the loss of their health follow, as the punishment of their former misconduct. Thus, then, to use the words of Bishop Butler, "There is a certain bound to imprudence and misbehaviour, which being transgressed, there remains no place for repentance in the natural course of things." If we then offend in our high capacity of rational and immortal beings, we have certainly no reason to expect that our repentance can of itself deliver us from that punishment, which God has annexed as the natural consequence of our transgressions. Thus, then, though it is evident that repentance is necessary, yet it is no less evident that it is not of itself sufficient to procure forgiveness.

In the second place, the alledged absurdity of vicarious suffering, or the injustice of an innocent person's suffering for the guilty, is another point at which Deists and Socinians make a stand, to combat the doctrine of atonement. But if good is to be produced, where is the absurdity of an innocent person suffering? This objection comes with a bad grace from a Socinian, who admits that Christ suffered; and alleges it as the reason, that we might be taught patience and resignation by his example. This is giving up the point at once, when it is admitted that Christ's sufferings were intended to teach us any useful lesson; for it is admitting that an innocent suffered for the benefit of the guilty. Indeed this is such a common occurrence, that to affirm it to be unjust would be to arraign the whole economy of providence, and the whole moral government of God; for we daily see the innocent suffering for the sake of the guilty: and in many cases the laws of all nations admit of a substitution, as a sufficient compensation for violated justice. In a thousand instances, nature and reason demand that we should interpose, and mitigate the sufferings of the imprudent or unfortunate, by bearing a share of their calamities. This is so very evident, that Grotius, in his tract *De satisfactione Christi*, c. 4., observes, *Ubi consensus aliquis antecederet, ferme ausim dicere omnium eorum quos Paganos diximus, neminem fuisse, qui alium ob alterius delictum puniri injustum duceret.*

But modern Socinians, or, as they call themselves, Unitarians, (and, indeed, there is a wide difference between some of their opinions and those of Socinus, who certainly approached much nearer to the orthodox system than they do,) have had the boldness to affirm, that the doctrine of atonement is not once to be found in scripture. This is maintained by Priestley, in his answer to Paine, with a view to render Christianity palatable to that unbeliever, by explaining away its most peculiar and most obnoxious doctrines. "The doctrines of atonement, incarnation, and the Trinity," says he, "have no more foundation in the scriptures than the doctrines of transubstantiation or transmigration." This is new ground indeed: we know that the scriptures have often been rejected, because they contained the

doctrine of atonement, &c.; but it was reserved for Dr Priestley and his associates to discover, that such doctrines were not to be found there. Neither the friends nor the enemies of Christianity had ever suspected such a thing before; and it would have been almost as easy to have persuaded them that Homer did not write of Troy, as that the evangelists did not write of the atonement. It is not once hinted at in the gospels, say these writers; we would be obliged to them, then, for a satisfactory explanation of these expressions: "the Son of man came not to be ministered unto, but to minister, and to give his life a ransom for many;" Mark, x. 45. "This is my blood of the new testament which is shed for many, for the remission of sins." And if we turn to the epistles, we can scarcely find a page where this doctrine is not either expressly taught or alluded to. If it is therefore to be reckoned among the corruptions of Christianity, as Dr Priestley affirms, we should be forced to conclude, that Christianity was corrupted by its founder, and that its first preachers exerted themselves to propagate a delusion. It is lamentable to see the judgment of a man, otherwise acute, so miserably warped by prejudice, as to be unable to discern the clearest truths. We shall see still farther reason for this observation, when we attend to the extraordinary position which he advances on another occasion: "From a full review of the religions of all ancient and modern nations, they appear to have been utterly destitute of any thing like a doctrine of proper atonement." Is it possible that such a sentiment should be seriously maintained by a divine, a scholar, and a historian,—a sentiment which any peasant might refute from the Jewish law, and any school-boy from the practice of ancient nations? What so common as expiatory sacrifices amongst all nations under heaven? and yet Dr Priestley could discover no vestiges of such a practice!

The death of Christ, according to Priestley and his followers, was intended to give us a proof of our resurrection and immortality, by his rising from the dead. But surely these doctrines were not so new, nor so uncommon, as to require such a proof: the doctrine of a resurrection was familiar to the Jews; and they had seen several actual proofs of its possibility: and the doctrine of the soul's immortality was received among all nations. Dr Priestley, indeed, who affirmed the soul to be nothing but a combination of matter, might reckon some extraordinary evidence necessary to prove its future existence: But the bulk of mankind did not deem such a proof necessary; for they had always believed in the soul's immortality. We do not deny that this doctrine, as well as many others connected with morality and religion, received the strongest confirmation by our Lord's instructions, death, and resurrection. But no one who receives the scriptures as the word of God, or indeed in any other sense, can fail to observe, that the great end of our Lord's death is uniformly stated to be, that he might make an atonement for the sins of men; nor can we see how his death, in any other view, should have at all been necessary; for all the other parts of his mission might have been completely accomplished without it. See Magee *On the Atonement*, and THEOLOGY. (g)

ATOOL, ATTOWA, ATTOWAY, or TOWI, one of the largest of the Sandwich Islands, situated in the Pacific Ocean, in one of the new divisions of the globe called Polynesia. According to some accounts, it is about thirty miles long from east to west, while others make

it about 300 miles in circumference. On the east side, the island rises with a gentle acclivity from the sea, and terminates in high land near the centre of the island. The elevated grounds are clothed with lofty trees, with the most luxuriant foliage; but, on descending to the eastern coast, the land is uncultivated, and almost deserted by the inhabitants. On the western shore the ground is more fertile, and the population more numerous. The chief productions of the island are sweet potatoes, yams, sugar cane, pepper, and a kind of oily nuts, which are stuck upon skewers, and used by the natives as candles. The island affords plenty of fresh water. The highest part of it is about 2130 yards from the level of the sea. Population 54,000. An account of the manners of the inhabitants, and other general observations, shall be given under the article SANDWICH ISLANDS. W. Long. 206° 20', or E. Long. 159° 40'; N. Lat. 21° 50'. See Marchand's *Voyage*, vol. ii. p. 80.; Cooke's *Voyages*, vol. iii.; Vancouver's *Voyages*, vol. i. p. 171. (o)

ATOPA, a genus of coleopterous insects in the arrangement of Fabricius and Cuvier, belonging to the family of *thoracicornes* of the latter. See ENTOMOLOGIA. (f)

ATTRACTYLIS, a genus of plants of the class Syn-genesia, and order Polygamia Equalis. See BOTANY. (w)

ATRAGENE, a genus of plants of the class Polyandria, and order Polygynia. See BOTANY. (w)

ATRAPHAXES, a genus of plants of the class Hexandria, and order Digynia. See BOTANY. (w)

ATREBATES, or ATTREBATES, a tribe of the Belgæ, who inhabited that country now called Artois. Their capital, according to Scaliger, was Origiacum, now Arras. They were a fierce and barbarous people, who, like the Nervii, their neighbours, scarcely admitted foreigners among them, and valued themselves on their want of refinement. The Atrebates were enthusiastic in the cause of liberty against Cæsar, and entertained the utmost contempt for the other Gauls who had submitted to his arms. The quota of troops which they furnished to the Belgic confederacy was 15,000 men, whom we afterwards find is a distinct body engaging some of the Roman legions in a river. Upon the defeat and dissolution of the Nervian confederacy, Cæsar set over them, in quality of king, their own countryman, Comius the Atrebatian. This man, who was a crafty time-serving politician, was also an expert general, and held a distinguished command under Cæsar in most of his Gallic and British campaigns. He at last quarrelled with his master, in the hope of acquiring his independence, and received a desperate wound in an action, where he was left on the field for dead. Being at last forced into submission, he was pardoned in consideration of his past services; and, on delivering hostages, was allowed to continue in his authority.

There is some mention of a people of the same name in Britain. The capital of the British ATREBATES, or, as our antiquarians call them, ATTREBATHI, is conjectured, from the name, to be the Calliva Attrebatum of Antonine's Itinerary, which seems to be the same with the Calca of Ptolemy. This obscure tribe were probably a Belgic colony, who, like some other communities on the British coast, had arrived but a short time before Cæsar's invasion. This may be inferred from the influence which Comius the Atrebatian was supposed to possess, when sent by the Romans to persuade the Britons to a voluntary submission. Whatever may be in this, or whether the Atrebatian adventurers ever ex-

isted in Britain as a distinct nation or not, this people, it is certain, soon disappeared, and little or no notice is taken of the name by ancient writers. They are placed by some of the antiquaries in Berkshire, by others in Oxfordshire, and by others in part of both. Calliva is supposed to be the present Wallingford, in the county of Berks. See Cæs. *De Bell. Gall.* l. 2., et passim.; *Cand. Brit.*; Horsley's *Brit. Rom.*; Henry's *Hist. of Britain.* (E)

ATREUS, king of Mycenæ, the son of Pelops, and father of Agamemnon and Menelaus. The accounts of this prince that are preserved in ancient authors will be found by consulting Plutarch in *Parall.*; *Pausan.* lib. 9. cap. 40.; Senec. in *Atr.*—*Apollod.* lib. 3. cap. 10.; *Hygin. Fab.* 85, 88, 258.; *Univers. Hist.* vol. vi. p. 162, 264. See also Lempriere's *Classical Dictionary*, Art *Atrus.* (w)

ATRIPLIX, a genus of plants of the class Polygamia, and order Monœcia. See BOTANY. (w)

ATROPIA, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY. (w)

ATROPIHY, (from *ἀ*, and *τροφή*, *to nourish*;) is a wasting of the body, from defect of nourishment. See MEDICINE. (j)

ATTACHMENT (from the corrupt Lat. *attachiare*; Fr. *attacher*, to tie or fasten), in the common law of England, signifies the taking or apprehending a person or thing, by a writ or precept issuing on commandment of a court.

Attachment differs from arrest: for in arrest, the person apprehended is carried before a person of higher authority, to be disposed of; whereas, he who attaches another, keeps and presents him in court on the day assigned, according to the terms of the writ: *præcipimus tibi quod attachias talem, et habeas eum coram nobis*, &c. There is also this other difference between an arrest and an attachment: the former is made only upon the body of a man; the latter frequently upon his goods.

Attachment is also a mode of punishing contempts, immemorially used by the superior courts of justice. Contempts, thus punishable, are either *direct* or *consequential*. The following are the principal instances of either kind: 1. Those committed by inferior judges and magistrates, by acting unjustly, oppressively, or irregularly, in the administration of justice; or by disobeying the king's writs issuing out of the superior courts. 2. Those committed by sheriffs, bailiffs, gaolers, and other officers of the court, by abusing the process of the law, or deceiving the parties, by acts of oppression, extortion, collusion, or culpable neglect of duty. 3. Those committed by attornies and solicitors, who are also officers of the respective courts, by any species of dishonest practice. 4. Those committed by jurymen, in collateral matters relating to the discharge of their office; such as making default when summoned, refusing to be sworn, or to give any verdict; eating and drinking without the leave of the court, &c. but not in the mere exercise of their judicial powers; as by giving a false or erroneous verdict. 5. Those committed by witnesses, by making default when summoned, refusing to be sworn or examined, or prevaricating in their evidence when sworn. 6. Those committed by the parties to any suit; as by disobeying any rule or order made in the progress of a cause, by non-payment of costs awarded by the court, or by non-observance of awards duly made by arbitrators or umpires. 7. Those committed by any other persons, under the degree of a peer, and even by peers themselves, when enormous, and accompanied

with violence, such as forcible rescous and the like ; or when they import a disobedience to the king's great prerogative writs, of prohibition, *habeas corpus*, &c.*

* There is an eighth species of contempt of the authority of courts of justice, known to the law of England, and which does not appear to be noticed in this article. We mean contempt by printing or writing, and publishing during the pendency of a cause, something tending to prejudice the public mind against the parties or judges, or the merits of the controversy. This species of contempt appears to have been not unfrequently punished by the English court of chancery under the summary process of attachment. Thus a captain Perry was attached and fined by that tribunal merely for having printed his brief before the cause came on. 2 *Atk.* 472.

The application of the same doctrine and mode of proceeding in the state of Pennsylvania has at different times excited considerable feeling. Shortly after the revolution, the press having become extremely free, a printer named Oswald was fined and imprisoned under the summary process of attachment, for having published reflections on his adversary, and indirectly on one of his judges in a cause then pending between himself and another printer. After undergoing his punishment, he applied by petition to the legislature to impeach the judges of the supreme court of this state who had passed sentence upon him ; but after a solemn argument by counsel on both sides, his petition was rejected by a respectable majority. 1 *Dall.* 329. From that time, however, the general doctrine of the English law respecting contempts, and particularly the summary mode of proceeding in such cases by attachment, became very unpopular, and at last in the year 1803, another individual having been fined and imprisoned by the supreme court for having posted up in a public place a written paper against his adversary in a cause then pending, a similar application was made to the legislature as in the former case, and an impeachment was actually preferred by the house of representatives against the chief justice and two of the associate judges, who, although they were acknowledged to be men of the most respectable character for learning, abilities and integrity, had to stand their trial before the senate, but were finally acquitted. The legislature soon after passed an act on the subject of contempts of court, of which the principal provisions are as follows :

1. No summary punishment to be inflicted for contempts of court, except in the following cases : 1. For official misconduct of the officers of the courts. 2. For the negligence or disobedience of officers, parties, jurors or witnesses against the lawful process of the court. 3. For the misbehaviour of any person in presence of the court, obstructing the administration of justice.

2. Publications tending to bias or influence the public mind respecting a depending cause not to be summarily punished, but the party to be proceeded against by civil action or indictment.

3. No contempts to be punished by imprisonment, but those committed in open court ; all others by fine only.

We do not find that the subject of contempts by publication respecting a cause depending has been agitated in courts of justice or legislative bodies in any of the

The process of attachment for these and the like contempts must necessarily be as ancient as the laws themselves : for it is obvious, that all laws would be vain and nugatory, without a competent authority vested in the courts to secure their administration from disobedience and contempt. Accordingly we find this process in use as early as the annals of our law extend.

Should the contempt be committed in the face of the court, the offender may be instantly apprehended and imprisoned, at the discretion of the judges, without any further proof or examination. But in the case of contempts arising out of court, if the judges upon *affidavit* see sufficient grounds for suspecting that a contempt has been committed, they either make a rule on the suspected party, to shew cause why an attachment should not issue against him ; or, where the contempt has been very flagrant, the attachment issues in the first instance ; as it does also, if no sufficient cause be shewn to discharge, and thereupon the court confirms and makes absolute the original rule.

The attachment is merely intended for bringing the offender into court. Thereafter he either stands committed, or puts in bail, and is interrogated upon oath with respect to the circumstances of the contempt. The interrogatories must be exhibited within the first four days. If the party clears himself, he is discharged ; but, if perjured, he may be prosecuted for the perjury. The mode of punishing contempts is by an arbitrary punishment, at the discretion of the court, according to the nature and magnitude of the offence.

Attachment is used in chancery, if the defendant, on service of the *subpoena*, fails to appear within the time limited by the rules of the court. It is a writ of the nature of a *capias*, directed to the sheriff, and commanding him to attach the defendant, and bring him into court. If the sheriff returns *non est inventus*, then there issues an *attachment with proclamations* ; which directs the sheriff to make public proclamations to sum-

other states of the union before or since the revolution ; we must therefore presume that it stands there entirely on the principles of the common law. It is proper to mention, however, that in the year 1801, before the decision of the case which gave rise to the act of assembly above mentioned, an attachment was ordered, after solemn argument by the circuit court of the United States for the district of Pennsylvania, against a printer, who, pending a cause in that court to which he was a party, had published a piece calculated to influence the public mind on the merits of the controversy, and he was finally adjudged to be fined and imprisoned for the contempt. *Wallace's Reports*, 77, 102. So that contempts of this description are still punishable by a summary process in Pennsylvania, when committed against the courts of federal jurisdiction, because the powers of the tribunals which sit under the authority of the general government cannot be restricted or modified by the acts of the state legislatures, which operate only on the judges appointed under their own local authority. Nay, we believe that it may be safely asserted that the decision in the case just mentioned is to be considered as establishing the law throughout the United States, as to causes depending before the federal courts, and that it can now only be altered by a contrary decision of the supreme court of the United States, or an act of congress.

DE POURCEAU.

mon the defendant, upon his allegiance, personally to appear and answer. If the defendant still persists in contempt, a *commission of rebellion* is awarded against him, and four commissioners are named, any one of whom is to attach him wheresoever he may be found in Great Britain, as a rebel and contemner of the king's laws and government. If a *non est inventus* is returned upon this commission of rebellion, the court then sends a *serjeant at arms* in quest of him; and if he still eludes the search, a *sequestration* issues to seize all his personal estate, and the profits of his real, to be detained, subject to the order of the court. After the issuing of an order for sequestration, the plaintiff's bill is to be taken *pro confesso*, and a decree made accordingly; the sequestration being only intended to enforce performance of the decree.

If the defendant is taken up upon any of this process, he is to be committed to the Fleet, or other prison, until he appears, or answers, or performs whatever else this process is issued to enforce, and also clears his contempts, by paying the costs incurred by the plaintiff.

A *writ of attachment, or pone** (so called from the words of the writ, *pone per vadum et salvos plegios* &c.) is a writ, not issuing out of Chancery, but out of the court of Common Pleas, founded on the non-appearance of the defendant at the return of the original writ; whereby the sheriff is commanded to attach him by taking *gage*, that is certain of his goods, which shall be forfeited if he does not appear; or by making him find safe pledges, or sureties, for his appearance. This process is also used, without any previous summons, upon actions of trespass *vi et armis*, or other injuries importing a breach of the peace, as *deceit* and *conspiracy*.

In case the defendant neglects to appear, the attachment is followed up by a writ of *distringas*, or *distress infinite*; and, in certain cases, a *capias* issues against the defendant's person. See DISTRESS and CAPIAS.

Foreign attachment, is an attachment of the goods of foreigners, found within some liberty, for the satisfaction of their creditors residing within such liberty.†

* This writ is not in use, that we know of, in any of the United States. DU Ponceau.

† It is a subject of wonder that this most beneficial process of foreign attachment is confined in England to the city of London and some other places in the kingdom, and that there is no general mode of proceeding to compel the appearance of an absent debtor, by the seizure in the first instance of his goods and outstanding credits. In this, the law of England differs from that of every other country in Europe. We have seen above, under the head ARRESTMENT *jurisdictionis fundandæ causâ*, that the law of Scotland has provided a general remedy analogous to the writ of foreign attachment, which, like the latter process, is not confined in its operation to particular places, but extends over the whole of the northern section of the island of Great Britain.

In the United States, the law is far from being uniform upon this subject. Several of the states have indeed established by law a mode of proceeding against absent debtors, similar, or analogous to the English writ of foreign attachment; but there are still some who have made no provision whatever on the subject, and others who have provided writs of attachment against

By the custom of some places, as London, &c. a man may attach money or goods in the hands of a stranger. But no foreign attachment can be had, while a suit is depending in any of the courts at Westminster. And no attachment can be had, but for a certain and due debt; although, by the custom of London, money may be attached before the term of payment, but not levied until due.

Foreign attachments in London, upon plaints of debt, are made in the following manner: A. owes B. 100*l.*; and C. is debtor to A. in the like sum. B. enters an action against A. for 100*l.*; and by virtue of that action, a serjeant attaches 100*l.* in the hands of C. as the money of A. to the use of B. which is returned upon that action.

After the attachment has been made and returned by the serjeant, the plaintiff must see an attorney, before the next court holden for the Compter; or the defendant may then put in bail to the attachment, and nonsuit the plaintiff. Four court days must elapse, before the plaintiff can call upon C. the *garnishee*, to shew cause why B. should not condemn the 100*l.* attached in the

the effects of fugitive and absconding debtors, which operate not so much as a mode to compel the debtor's appearance to the suit of a particular creditor, as to secure his property for the benefit of his creditors at large. Such, for instance, is the law in the state of New-York. In Pennsylvania, proceedings have been devised by the legislature to obtain both the above desirable ends. There is a writ of *foreign attachment*, by which a foreign debtor may be compelled to appear and make answer to the lawful demand of one or more of his creditors, and a writ of *domestic attachment*, which is somewhat in nature of the proceedings under a commission of bankrupt in England. The object of the first process is to compel the appearance of a debtor, whether foreigner or native, who is not domiciled in the state, and oblige him to answer to the suit of the attaching creditor, while that of the latter is to secure to the creditors at large the effects of a resident debtor who has absconded from his place of abode. This distinction appears founded on the most correct principles of distributive justice. The resident debtor having obtained a general credit in the state, and having by his flight or absconding given sufficient evidence of his insolvency, the state is in a manner bound to distribute his effects among the generality of his creditors, while in the case of a foreign debtor, whom our laws cannot declare bankrupt or insolvent, each individual creditor is entitled to the exclusive benefit of the legal proceedings which he thinks proper to institute.

In the state of Massachusetts, the process of attachment to compel appearance to an action for debt may be used against all persons, present as well as absent. It is there the usual mode of instituting a suit. A writ is obtained by which the sheriff is commanded to attach the goods of the defendant, if they can be found to a certain amount; if not, to take his body, so that he appear and answer the plaintiff's demand. When the goods are seized, the sheriff cannot release them, unless sufficient security is given for their forthcoming to abide the judgment of the court. This mode of proceeding, we are informed, has been long established in that state, and has not been found to produce any material inconvenience in practice. DU Ponceau.

hands of C. as the money of A. the defendant. And the garnishee may appear by his attorney, and plead that he hath no money of the defendant's in his hands, or other special matter. But the plaintiff may hinder his waging of law, by producing two sufficient citizens to swear that the garnishee had either money or goods belonging to A. in his hands, at the time of the attachment; of which *affidavit* must be made before the Lord Mayor, and when filed, may be pleaded by way of *estoppel*.

If the garnishee neglects to appear by his attorney, after being warned by the officer, he is taken by default, for want of appearing, and judgment given against him; for which he has no remedy either at common law or in equity. But if the garnishee does appear and plead, the matter will then be tried by a jury, and judgment awarded, &c.

After trial, bail may still be put in, whereby the attachment shall be dissolved; but the garnishee and his security shall then be liable for whatever sum the plaintiff shall make out to be due upon the action. An attachment is never thoroughly perfected, until there is a bail and satisfaction upon record.

Attachment of privilege,* is where a person, by virtue of his privilege, calls another into that court to which he himself belongs, there to answer some action. Or, it signifies the power of attaching a man in a place privileged.

Corporation-courts have sometimes the privilege, by charter, of issuing attachments; and some baron-courts issue attachments of debt.

Attachments, court of, Wood-mote, or forty-day's court, is one of the *forest-courts*, instituted for the purpose of enquiring into all offenders against vert and venison. See *COURTS of Forest*. Blackst. *Comment.* Jacob's *Law Dict.* (z)

ATTACK. See MILITARY TACTICS.

ATTAINDER† in law, is the immediate and inseparable consequence of a sentence of death. When this highest judgment known in the laws of England is pronounced, a mark of infamy is thereby set upon the criminal; he is thenceforth put out of the protection of the law, which now takes no farther notice of him, than merely to see him executed. He is then said to be attainted, (*attinctus*, stained or blackened.)

There is a wide difference between conviction and attainder. A man is convicted, when he is found guilty by verdict, or confession, before judgment had: but there is still, in the contemplation of the law, a possibility of his innocence. Something may be offered in arrest of judgment; the indictment may be erroneous; he may obtain a pardon, or be allowed the benefit of clergy; both of which plead in extenuation of his offence. But upon judgment given, both law and fact conspire to prove him completely guilty; and there is no longer a possibility of any thing being said in his favour.

A person may be attainted on appearance, or by process. Attainder on appearance is by confession, or verdict, &c. Attainder by process is when a criminal flies, and cannot be found; when, after being five times proclaimed in the county, he is at length outlawed upon this default.

A person may likewise be attainted by act of parlia-

ment.* *Acts of attainder* have been passed in several reigns, since the attainder of persons guilty of the murder of Charles I. in the reign of Charles II., down to the present times. In passing bills of attainder no evidence is required.

Attainders may be reversed or falsified by writ of error, or by plea. In the former case, it must be by the king's leave: in the latter, by denying the treason, pleading a pardon by act of parliament, &c.

The consequences of attainder are FORFEITURE, and CORRUPTION of Blood. See Blackst. *Comment.* b. iv. ch. 29. Jacob's *Law Dict.* (z)

ATTAINT, WRIT OF, is a writ which lies to enquire, whether a jury of twelve men have given a false verdict, in any court of record; in order that the judgment following upon that verdict may be reversed. It is so called, because the party who obtains it, thereby endeavours to stain or *taint* the credit of the jury, in consequence of whose verdict he feels himself aggrieved. This writ must be sued out in the lifetime of him in whose favour the verdict was given, and of, at least, two of the jurors who gave it.

At common law, this writ originally lay only upon verdicts in actions for such *personal* injuries as did not amount to trespass; because, in *real* wrongs, the party aggrieved had redress by *writ of right*. And it did not lie in the action of trespass, for this singular reason: that if the verdict were set aside, the king would lose his fine. But by stat. Westm. 1. 5 Edw. I. c. 38, it was given in all pleas of land, franchise, or freehold; and by several subsequent statutes, in the reign of Edward III. and his grandson, it was allowed in almost every action, except in a writ of right.

Twenty-four jurors are required to try this false verdict; who are called the *grand jury*. He that brings the attaint can give no other evidence to the grand jury, than what was originally given to the petit; because the question is solely, whether the petit jury did right upon the evidence brought before them? But those against whom the attaint is brought are allowed to bring new matter, in affirmance of the first verdict; because the petit jury may have formed their verdict upon evidence of their own knowledge, which never appeared in court; and because the judgment inflicted upon them, at common law, if their verdict was found to be false, was peculiarly severe. This judgment was: That they should lose their *liberam legem*, and become for ever infamous; that they should forfeit all their goods and chattels; that their lands and tenements should be seized into the king's hands; that their wives and children should be turned out of doors; that their houses should be rased and thrown down; that their trees should be rooted up; that their meadows should be ploughed; that their bodies should be cast into gaol; that the party should be restored to all that he had lost in consequence of the unjust verdict. The severity of this judgment, however, was mitigated by the statute 11 Hen. VII. c. 24. revived by 25 Hen. VIII. c. 3. which inflicted a more moderate punishment upon attainted jurors; viz. perpetual infamy, and, if the cause

* *Attachment of privilege* is not in use, that we know of, in the United States. DU PONDÉAU.

* By the constitution of the United States no bill of attainder can be passed by the legislature, and no attainder of treason is to work corruption of blood or forfeiture, except during the life of the person attainted. There are similar provisions in the constitutions of the different states. DU PONDÉAU.

of action were above 40*l.* value, a forfeiture of 20*l.* each by the jurors; or, if under 40*l.* 5*s.* each; to be divided between the king and the injured party. So that an attaind may now be brought, either upon the statute, or at common law. But the practice of setting aside verdicts upon motion, and granting *new trials*, has now superseded the use of both sorts of attainds. See Blackst. *Comment.* b. iii. ch. 25. Jacob's *Law Dict.* (z)

ATTALUS, the name of several kings of Pergamus. See *Univ. Hist.* vol. vii. p. 263, 327, 332; viii. 189; x. 20, 40, (M); xii. 408; and *History of Free Masonry*, Edinburgh, 1804, p. 29. (j)

ATTELABUS, a genus of coleopterous insects, belonging to the family *Rostricornes* of the French naturalists. See ENTOMOLOGY. (j)

ATTENDANT KEYS, in music, are, according to Dis Boyce and Calcott, the keys on the fifth above, and fifth below, (or fourth above) any given key which in modulation are introduced, by the addition of a new sharp or flat to the signature. Mr Maxwell, p. 267. of his "Essay on Tune," proposes a system of 18 notes in the octave, which shall make the keys of C major and A minor, with their attendant keys, or 6 auxiliary scales, perfect in their harmony throughout. See Maxwell's *Scales of Music*, and AUXILIARY Scales. (z)

ATTENTION, a steady exertion or due application of the mind to any object of sense or intellect, in order to its being thoroughly understood, and afterwards retained. In its etymology it denotes *stretching* or *straining*, from *ad* and *tendo*, which not inaptly expresses that strong and undivided effort of our powers, which is required for giving to an interesting object its due impression.

Whether attention be a distinct and independent power of the mind, which cannot be resolved into any thing else; or whether it consist merely in a steady and strenuous exercise of any one of our various mental powers, or organs of external perception, according as the case may require, are questions on which philosophers have differed considerably in opinion. All, however, have agreed, that this species of mental exertion is indispensable, in order that objects may affect our faculties to such a degree as to be afterwards retained in the mind, or distinctly recollected. "Memory," says Mr Locke, "depends much on attention and repetition." *C'est l'attention*, says Helvetius, *plus ou moins grande, qui grave plus ou moins profondément les objets dans la mémoire.* And Quintilian makes a similar observation. *Nec dubium est*, says he, speaking of memory, *quin plurimum in hac parte, valeat mentis intentio, et velut acies luminum a prospectu rerum quas intuetur non aversa.* These remarks seem to imply, that attention is voluntary on our parts; and so it doubtless is to a certain extent; but when we are occupied by a very interesting object, our attention is seized, and fixed beyond our own controul.

In those cases where our attention is entirely engrossed by something that greatly interests the mind, the impressions on the organs of sense seem to produce no corresponding effect on our internal powers of perception. A clock, for example, may strike in the room where we are, and if we be deeply engaged in conversation, or in any interesting speculation, we shall not be able, the next moment, to recollect whether we heard it or not. The most acute sensation of pain may pass unnoticed, if the attention be vigorously directed to another object. In the tumult of a battle, a man may

be shot through the body without knowing any thing of the matter, till he discovers it by the loss of blood or of strength. And Archimedes, while intent upon the solution of a problem, was altogether unconscious of the sacking of Syracuse. In such cases we are apt to conclude, that the objects which act upon our senses have lost their influence upon our perceptive powers; though the truth rather seems to be, that perception still takes place, but that we are unconscious of it, because our attention is completely engrossed by some other object. That this is really the case, seems proved by a variety of facts. Thus a person who falls asleep in church, and is suddenly awaked, is unable to recollect the last words of the preacher; and yet that they affected his perceptive powers appears from this, that he would have instantly awaked, had the preacher made a sudden pause in his discourse.

It seems, therefore, to be essential to memory, even in the very lowest degree, that the perception or thought which we wish to remember should remain in the mind for a certain space of time, and should be contemplated by it exclusively of every thing else; otherwise it will not be recollected even the very moment after it has been present in the mind. Hence it happens, that, in solitude, or the stillness of the night, when the attention is undistracted by surrounding objects, the impression made by any single object is very strong and deep, and the memory becomes extremely retentive; and hence, in the hurry of business, and bustle of society, the objects which press upon us in rapid succession make but a fleeting impression upon the mind, and efface each other from our recollection.

It is an important question in the subject of attention, whether we have the power of attending to more than one thing at the same instant; or, in other words, whether we can attend at one and the same instant to objects which we can attend to separately. This question has usually been decided in the negative; it being supposed to be impossible that the mind can bend its thoughts upon more than one thing at the same time. It is a consequence of this doctrine, that in a concert of music, instead of attending to the different parts of the performance all at once, so as to feel the full effect of the harmony, the mind must constantly vary its attention from one part of the music to another, although its operations are so rapid as to give us no perception of an interval of time. "The same doctrine," says Mr Stewart, "leads to some curious conclusions with respect to vision. Suppose the eye to be fixed in a particular position, and the picture of an object to be painted on the retina; Does the mind perceive the complete figure of the object at once, or is this perception the result of the various perceptions we have of the different points in the outline? With respect to this question, the principles already stated lead me to conclude, that the mind does at one and the same time perceive every point in the outline of the object, (provided the whole of it be painted on the retina at the same instant) for perception, like consciousness, is an involuntary operation. As no two points, however, of the outline are in the same direction, every point by itself constitutes just as distinct an object of attention to the mind, as if it were separated by an interval of empty space from all the rest. If the doctrine, therefore, formerly stated be just, it is impossible for the mind to attend to more than one of these points at once; and as the perception of the figure of the object implies a

knowledge of the relative situation of the different points with respect to each other, we must conclude, that the perception of figure by the eye is the result of a number of different acts of attention. These acts of attention, however, are performed with such rapidity, that the effect, with respect to us, is the same as if perception were instantaneous.

“In farther confirmation of this reasoning, it may be remarked, that if the perception of visible figure were an immediate consequence of the picture on the retina, we should have at the first glance as distinct an idea of a figure of a thousand sides, as of a triangle or a square. The truth is, that when the figure is very simple, the process of the mind is so rapid, that the perception seems to be instantaneous; but when the sides are multiplied beyond a certain number, the interval of time necessary for these different acts of attention becomes perceptible. It may perhaps be asked, what I mean by a *point* in the outline of a figure, and what it is that constitutes this point one object of attention? The answer, I apprehend, is, that this point is the *minimum visible*. If the point be less, we cannot perceive it: if it be greater, it is not at all seen in one direction.” *Elements of the Philosophy of the Human Mind*, c. 2.

This doctrine, however, that the mind is incapable of attending to more than a single object, at one and the same instant of time, has been controverted by various able philosophers, who conceive it to be founded on a false analogy supposed to exist between the properties of body and those of mind. Material space, it is well known, must be completely occupied by a single body, to the exclusion of every other from that portion of it which the body fills; but what reason have we to ascribe such a quality as this to mind? Where is the analogy between the understanding and external space; or between a mere notion of the intellect, and an impenetrable piece of matter? On the contrary, there seems a kind of necessity, in certain cases, for admitting that the mind can attend at the same moment to objects which may also be made separate objects of attention, otherwise it does not appear how the relations and points of comparison between those objects can be satisfactorily understood. How, for example, can we discern the harmony between two musical notes, unless both are present to the mind together? Or how can we draw a conclusion from a comparison of two or more connected truths, unless we contemplate these truths in the mind at one and the same moment? Every syllogism is formed, by comparing together two propositions, called the major and the minor; and it seems necessary, before we can form a legitimate inference, that these two propositions should, at the same instant, be objects of our attention.

“Many single words,” says Dr Gregory, “for example propositions, and most sentences, denote some kind of relation; but we cannot, I think, conceive a relation, without thinking at once of the things (two or more) that are related, as well as of the relation (both in its generic and in its specific nature) that subsists between them.” This author is of opinion, that, with respect to the moods and other inflections of verbs, there cannot be a doubt that they are employed to denote combinations of *simultaneous* thoughts, no one of which can reasonably be said to occur to the person speaking, or to be apprehended by the person hearing, before the rest: and that all nouns, even proper names,

denote a congeries of circumstances, or *mass* (not a *train*) of thoughts, which are conceived at once, and cannot be separated and considered in succession, but by a very laborious effort. See *Theory of the Moods of Verbs*, *Edin. Phil. Trans.* vol. ii.

Various remarkable examples are upon record of the great power of undivided attention possessed by certain individuals, and of the capacity of apparently attending at the same moment to more than one important and interesting concern. Fontenelle relates of the celebrated mathematician Montmort, that he could command his attention at pleasure, insomuch, that in the same chamber where he was at work on the most complicated problems, his children might be as noisy as they pleased, or might dance and play upon the harpsichord. The famous chess-player Philidor, it is well known, could direct three games of chess at the same instant, of one of which only he required ocular inspection, the moves of the other two being merely announced to him by an assistant. And it is recorded of Julius Cæsar, that while he was writing a dispatch, he could at the same moment dictate four others to his secretaries: if he did not write himself, he could dictate seven letters at once. See Stewart’s *Phil. of the Mind*, c. 2. Helvetius *De l’Esprit*. Condillæ *Sur l’Origine des Connoiss. Hum.* s. 2. c. 1. Reid’s *Intell. and Active Powers*. (n)

ATTENUANTS, or ATTENUATING MEDICINES, are those which are supposed to diminish the consistence of the blood, or secreted fluids. See MEDICINE. (j)

ATTERBURY, FRANCIS, was the son of Dr Lewis Atterbury, rector of Milton, in Buckinghamshire, and was born there in 1662. He was educated at Westminster school, and in 1680 became a student in Christ-Church College, Oxford, where, in 1684, he took the degree of Bachelor, and in 1687 that of Master of Arts. In 1690 he married a lady of the name of Osborn, and about the same time entered into holy orders. He went to London in 1693, where he was elected preacher at Bridewell, and lecturer at St Bride’s Church. Soon after this he was appointed one of the chaplains in ordinary to King William and Queen Mary, and in 1700 he was installed arch deacon of Totness. Upon the accession of Queen Anne, in 1702, he became one of her majesty’s chaplains in ordinary; in 1704 he was advanced to the deanery of Carlisle; in 1707 he was appointed one of the canons residentiary at Exeter; and in 1709 he was made preacher at Roll’s chapel. In 1710 he was chosen prolocutor of the lower house of convocation; in 1712 he was made dean of Christ-church; and in 1713, at the recommendation of the Earl of Oxford, he was promoted to the bishopric of Rochester, and deanery of Westminster.

This rapid succession of promotions seems only to have kindled Atterbury’s ambition for still higher exaltation. It is said that he aspired to the primacy of all England, and that he had taken such measures as would in all probability have secured it upon a vacancy, had not the queen’s death, in 1714, prevented all his plans, and put an end to his prosperity. He soon found that he was not held in the same estimation by her successor George the First, and he himself soon began to manifest his disaffection to the reigning family. At a time when every man who held such a station as Bishop Atterbury, and who was not hostile to government, would naturally have felt himself called upon to express his decided disapprobation of the plans of the house of Stuart, he re-

refused to sign a declaration which the bishops had published against the proceedings of the pretender; and he strengthened all the unfavourable impressions of this refusal, by keenly opposing the measures of the court. At length, in 1722, he was apprehended upon a suspicion of being engaged in a conspiracy to restore the Stuart family. His papers were seized, and he was committed to the Tower. A bill was soon after brought into the House of Commons, "for inflicting certain pains and penalties on Francis, Lord Bishop of Rochester;" but he reserved his defence till it should be argued in the House of Lords. There the bill met with much opposition, and engaged the attention of the House for more than a week. The bishop spoke in his own defence with great ability and eloquence, and concluded with a solemn protestation of his innocence. But the bill was at length passed, by a majority of 83 to 43, and Atterbury was condemned to perpetual exile. The king, it is said, when he confirmed the bill, expressed his regret that there should be just cause for inflicting such a punishment upon a bishop of the Church of England, and a man of such eminent abilities and attainments. His daughter, Mrs Morrice, was permitted to accompany him; and, by the king's sign manual, his son-in-law, Mr Morrice, had leave to correspond with him. He left England in June 1723, and landed at Calais, whence he went to Brussels, and thence to Paris.— There he resided, for the most part, until his death, which took place on February 15, 1731, and which was supposed to be hastened by the loss of his daughter, two years before. His body was brought over to England, and interred in Westminster Abbey.

The literary productions of Bishop Atterbury were not very voluminous, but were considerable in point of number and variety. While a student at Oxford, he was distinguished for his taste in polite literature. During that period, he wrote a version, in Latin verse, of Dryden's *Absalom and Ahitophel*, an Epigram on a Lady's Fan, and a Translation of two Odes of Horace. His translations from Horace are considered as the best that have been made from that poet into the English language; and though their merit has perhaps been rated rather high, yet they certainly possess much of the lively spirit and graceful expression which characterise the original. From these indications of a poetical talent, which he gave in the early part of his life, many have concluded that he was peculiarly qualified for that spe-

cies of writing, and have lamented that he did not continue to cultivate his powers as a poet.* His next production was of a very different complexion, and, instead of trifling with the muses, he appears defending Luther and the reformation with great acuteness and learning. He referred to this publication at his trial, as an evidence that he had no secret inclination to Popery; and, on account of this performance, Bishop Burnet ranks him among the most eminent defenders of the protestant cause. He is supposed to have assisted the Honourable Mr Boyle, (afterwards Earl of Orrery,) who was under his tuition at Oxford, in the celebrated controversy which that nobleman carried on with Bentley, respecting the authenticity of the epistles of Phalaris. But the most extensive literary contest in which he engaged, was with Dr Wake, (afterwards archbishop of Canterbury,) concerning the rights of convocations. Dr Wake supported the following positions: "1st, That the right of calling the clergy together in synods is vested solely in the prince; 2dly, That the clergy, so assembled, have no right to debate or determine any point of doctrine or discipline without his permission; 3dly, That the prince may annul, alter, or suspend, the execution of any of their constitutions or decrees; and lastly, that no synod can dissolve itself without consent of the prince." Atterbury opposed these principles, and asserted the right of the clergy to meet and deliberate without any licence or qualification. Several pamphlets were written on both sides by different persons; but Bishop Atterbury was the most active and able advocate of the high church principles and party. In this, as in all his controversial writings, he expressed himself in very intemperate language, and frequently (if we may believe Bishop Burnet) with no very strict adherence to truth.† He received, however, the thanks of the lower house of convocation, for his zeal in asserting the rights of the clergy, and was complimented by the university of Oxford with the degree of doctor in divinity. He had been appointed by the convocation one of the committee for comparing Mr Whiston's doctrines with those of the church of England; and, in consequence of this appointment, he was principally concerned in drawing up "a representation of the present state of religion." In this performance, which Bishop Burnet calls "a virulent declamation," he contrives to throw the blame of the national wickedness upon those who had lately been in power, and even seeks occasion

* As a specimen of Bishop Atterbury's compositions in poetry may be given his Epigram on a Lady's Fan, which was addressed to the lady who afterwards became his wife.

Flavia the least and slightest toy
Can with resistless art employ.
This fan, in meaner hands, would prove
An engine of small force in love;
Yet she, with graceful air and mien,
Not to be told or safely seen,
Directs its wanton motions so,
That it wounds more than Cupid's bow:
Gives coolness to the matchless dame,
To every other breast a flame.

† "Some books," says the bishop, "were wrote to justify it, (the complaint of the high church party, of the want of convocation,) with great acrimony of style, and a strain of insolence that was peculiar to one Atterbury, who had indeed very good parts, great learning, and was an excellent preacher, and had many extraordinary things in him, but was both ambitious and virulent out of measure, and had a singular talent of asserting paradoxes with a great assurance, shewing no shame when he was detected in them, though this was done in many instances: But he let all these pass, without confessing his errors, or pretending to justify himself. He went on, still venting new falsehoods in so barefaced a manner, that he seemed to have outdone the Jesuits themselves." *History of his own Time*, vol. ii. p. 249.

to accuse all the administrations since the Revolution. Before his death he published a vindication of himself, Bishop Smallridge, and Dr Aldrich, from a charge of having altered and interpolated Lord Clarendon's History of the rebellion. While he resided in France, he corresponded with many literary characters, and particularly with a M. Tournier, who has published several of the bishop's letters, which consist chiefly of criticisms on several French authors. His letters to Mr Pope also are preserved, along with the letters of that poet; and it is in this correspondence that his character appeared in the most engaging point of view. The letters of Atterbury are accounted superior to those of Pope, in ease and elegance of expression; but the sentiments expressed in them are very irreconcilable with that restless ambition, by which he seems to have been actuated in almost every period of his life. The Sermons of Bishop Atterbury may be considered as his principal work, and as having laid the foundation of his character as a writer. They are now extant in four volumes octavo; of which the two first volumes were published by himself, and the two last by his chaplain Dr Moore. The sermons, however, which Dr Moore has published were marked by the bishop's own hand as the only ones fit to be printed; and all the rest which he had written were committed to the flames, partly by himself, and partly by his executors. Several of his sermons were severely attacked by Mr Hoadly; and he had a dispute with the same writer on the subject of passive obedience. In the course of that controversy, Hoadly clearly shewed, that Atterbury contradicted the sentiments which he himself had advanced when supporting the rights of convocation. In the sermons also, which Hoadly censured, there are several very unguarded positions and unscriptural tenets. Notwithstanding these defects, his appearance in the pulpit seems to have gained him many admirers, and has even been considered as the principal cause of his preferments. Though there is much reason to doubt this, yet it is undeniable, that they are among the best pulpit compositions of that age, and they still maintain a very respectable character in the opinion of all candid and judicious persons.* They scarcely, however, deserve the high praise which has been given them, for clear and convincing argument; but, like all the writings of Atterbury, they are more remarkable for correctness and

case, than for strength and elegance of language; for clear and concise illustration, than for forcible reasoning and animated eloquence.

Upon examining the literary compositions of Bishop Atterbury, there appears, at one glance, the most abundant reason to acknowledge his great abilities, taste and learning; but, upon a review of the history of his life, it is not easy to find equally striking indications of an upright moral and political character. While contemplating him in this view, it is no doubt necessary to keep in mind the turbulence of the times in which he lived, and the political contentions in which he had so great a share. It may easily be conceived, that in such a scene, his activity and zeal, in whatever cause he espoused, would draw from his friends more frequent and pointed eulogies than he really deserved, as well as excite in his opponents stronger prejudices, and keener reproaches, than strict justice authorised. But, after making all reasonable allowances for the partialities of party, and following the fairest medium of judgment, it is not easy to form a very favorable estimate. It is known, that, in open defiance of all propriety and principle as a clerical character, he was accustomed to swear upon any strong provocation; that he was even amongst the foremost and keenest in every political contest which occurred in his time; that, in the different stages through which he passed in the course of his church preferments, he was involved in quarrels; and that Dr Smalridge, who succeeded him in two of the stations which he had filled, complained of his hard fate, in being obliged "to carry water after him, to extinguish the flame which his litigiousness had every where occasioned." From merely attending, then, to the acknowledged tenor and transactions of Bishop Atterbury's life, it appears too evident, that he was a man of a hot temper, and haughty spirit; ambitious of preferment, and jealous of his rights; violent in his public proceedings, and ready for political contention; cautious and cunning in general, yet frequently prompted by passion to expose his own reputation, and to injure his most favourite cause. There is no good ground for suspecting, that he was either inclined to infidelity,† or even favourable to Popery; but, besides the evidence advanced on his trial, there are several uncontroverted facts, which clearly indicate his attachment to the Stuart family, and which strongly tend

* A writer in the Tatler gives the following very high commendation of Bishop Atterbury's talents as a preacher, and particularly of his powers in elocution:

"He has so particular a regard to his congregation, that he commits to memory what he has to say to them; and has so soft and graceful a behaviour, that it must attract your attention. His person, it is to be confessed, is no small recommendation; but he is to be highly commended for not losing that advantage, and adding to the propriety of speech (which might pass the criticism of Longinus) an action which would have been approved by Demosthenes. He has a peculiar force in his way; and has many of his audience, who could not be intelligent hearers of his discourse, were there not explanation as well as grace in his action. This art of his is used with most exact and honest skill. He never attempts your passions till he has convinced your reason. All the objections which you can form are laid open and dispersed, before he uses the least vehemence in his sermon; but when he thinks he has your head, he very soon wins your heart; and never pretends to shew the beauty of holiness, till he has convinced you of the truth of it. B"

† The following anecdote is given by Dr Maty, on the authority of Lord Chesterfield, as a proof of Bishop Atterbury's scepticism with regard to revelation:

"I went to Mr Pope," says Lord Chesterfield, "one morning, at Twickenham, and found a large folio Bible, with gilt clasps, lying before him upon his table, and, as I knew his way of thinking upon that book, I asked him jocosely, if he was going to write an answer to it? It is a present, said he, or rather, a legacy, from my old friend the Bishop of Rochester. I went to take my leave of him yesterday in the Tower, where I saw this bible upon his table. After the first compliments, the Bishop said to me, my friend Pope, considering your infirmities, and my age and exile, it is not likely that we should ever meet again, and therefore I give you this legacy, to remember me by it. Does your lordship abide by it yourself? I do. If you do, my lord, it is but lately. May I beg to know what new light, or arguments, may have prevailed with you now to entertain an opinion so contrary to that which you entertained of that book all the former part of your life? The Bishop replied, we have not time to talk of these things; but take home the book; I will abide by it, and I recommend to you to do the same; so God bless you." This story, which rests entirely upon the authority of Lord Chesterfield, seems to be now generally discredited. It is not only altogether uncorroborated, but is, on the contrary, clearly contradicted, by numberless circumstances in the Bishop's life and writings; and it has been directly confuted, in a very satisfactory manner, from a mere comparison of dates. See *Epistolary Correspondence, &c.* of the Bishop of Rochester, published by Mr Nichols, vol. ii. p. 79. Not s

to confirm the charge of his having been engaged in treasonable practices for their restoration.* But however much his personal concern in such plots may be doubted, and his disaffection to the reigning family excused, yet there is no adequate apology which can be made for the turbulence of his public proceedings, and no sufficient substitute to be found, among all his excellencies and attainments, for that humility and meekness, that love of peace and of good order, which became him as a christian bishop, but in which he was so extremely deficient. Even they who approve his principles as a high churchman, or who sympathise with his feelings as a friend of the Pretender, will not be able to vindicate the means which he used, and the spirit which he displayed, in supporting what, perhaps, he sincerely considered as just and right. He may claim our admiration for his natural endowments and acquired accomplishments: he may stand high in our opinion as an acute politician and an active partisan: and he may be contemplated with approbation in his intercourse with his family and friends: but his title is not so valid to that true greatness, which consists in self government, integrity, and candour; nor can he even be admitted to have possessed any great share of that moral worth, which can attach to any man only by supporting consistently that character which he assumes, and by discharging consistently those duties which belong to him in his particular place and station. See Stackhouse's *Memoirs of Dr F. Aterbury*; and *Biograph. Britannica*. (g)

ATTICA, a country of Greece, immediately to the east of Peloponnesus, from which it is separated by the Saronic Gulf. That gulf and the Ægean Sea form it into a species of peninsula. By land, it joins with Bœotia. The soil is barren, except in olives, for which it has always been famous, and in honey, which it produces copiously, and of the best quality, from Mount Hymettus.

The people of Attica were anciently divided into ten tribes, who derived their names from the most distinguished of its heroes. Three were afterwards added, in compliment to Ptolemy, king of Egypt, Attalus, king of Pergamus, and the emperor Adrian. These were subdivided into a hundred and seventy-four communities, the names of which have been searched out by the learned with indefatigable industry. They are given in Meursius (*Attica*) or more correctly in Spon, (*Voyage d'Italie*), where they may be found by any one who is desirous of such barren information.

Attica is chiefly distinguished as having for its capital Athens, in treating of which, we have given a full detail of its history. Besides Athens, it contained Eleusis, Sunium, and Marathon. (p)

ATTICUS, TIBERIUS CLAUDIUS HERODES, an opulent and munificent citizen of Athens. He was descended from a noble family of large possessions in the district of Marathon, whose lineage was traced back as far as Miltiades, the great hero of the place. His grandfather, Hipparchus, having been proscribed, and his property confiscated, Julius Atticus, the father of He-

rodes found himself in a state of poverty, or rather feigned himself to be so: for when the good Nerva reigned, he discovered an immense treasure in his own house. Filled, it is pretended, with terror, rather than joy at this discovery, he immediately wrote a letter to the emperor in these words: "I have discovered, O emperor, a treasure in my house; what do you order to be done with it?" The answer of Nerva was equally laconic: "Use what you have found." Julius wrote back, that it was "more than he could use." "Abuse it then," replied the emperor; "for it is your own." Julius after this resumed the proper rank of his family; and this fortune, together with other possessions, paternal and maternal, which soon accumulated in the person of his son, rendered him the richest individual that Attica ever produced.

Herodes possessed excellent talents, which fitted him to shine in any situation. His attention, however, was principally directed, according to the taste of the age, to the study of rhetoric, in which he made distinguished proficiency under Scopelian, and other masters of repute: and such was the force and propriety of his eloquence, that, when yet a youth, he was selected to be the head of a deputation to the emperor Hadrian, who was then at Sirmium in Pannonia. The situation, however, was new. Young Herodes failed in his attempt to deliver a speech, and was so mortified at his misfortune, that he had some thoughts of throwing himself into the Danube. But this precipitate resolution was soon succeeded by a more rational remedy. Far from being disgusted by the accident with his favourite pursuit, he, on the contrary, redoubled his perseverance; and attained to such eminence in eloquence and philosophy, that he still lives, in biography, among the orators and wise men of Greece and Rome. His great celebrity attracted the attention of Titus Antoninus, who appointed him to the high and honorable office of preceptor in eloquence to his two sons, M. Aurelius and L. Verus. From this station Herodes ascended to the summit of greatness, and was created consul A. D. 143. He was also constituted president of the Panhellenic and Panathenæan festivals, on which occasion he was crowned.

At a very early period, he obtained the government of the free cities in Asia, where he distinguished himself by many acts of munificence. Having observed that the chief city of Troas was badly supplied with water, he obtained from Hadrian a grant of three millions of sesterces for the construction of an aqueduct; but such was his natural attachment to grand designs, that he laid out seven millions instead of three, in the execution of it. Of this profusion Hadrian complained to the father of Herodes, who, on that occasion, is noted by the ancient writers for one of the most magnificent replies ever made to an emperor. "Hadrian," said the father, "be not discomposed by small matters: whatever he has spent above the three millions, my son shall defray out of my fortune."

The death of his father occasioned a considerable quarrel between Herodes and his fellow citizens. Julius had lived more like a prince than a private man among the Athenians. His enormous wealth enabled him to distribute to that abject people the most ample largesses

* It is certain that he suspended, for three years, a Mr Gibbon, curate of Gravesend, a clergyman of worth and learning, because he had granted the use of his church for divine service to the Dutch troops, who came to assist in subduing the rebellion. And a pamphlet, published at Edinburgh in 1768 by Lord Hailes, the authenticity of which has never been questioned, details his correspondence in 1725 with several gentlemen in the north of Scotland, for the purpose of exciting commotions in favour of the Pretender. Thus, while in his letters from France he professes to have nothing in view but a quiet, literary, social life, and still to retain a warm attachment even to that part of the constitution which had injured him, he was actually engaged in moving and directing a scheme for rebellion and sedition.

ever heard of. He sacrificed a hundred bees in one day, and regaled the whole Athenian people by tribes and classes on several occasions. In his last will, he bequeathed to each individual, for life, an annuity of one *mina*, or about three guineas sterling; a sum which, in those days, was very considerable. This enormous bequest, dictated more by patriotism than sound judgment, was but ill relished by Herodes, who resolved to withhold it. Having for this purpose got the people to an agreement, that, on his paying down five *Minæ* at once, he should be relieved from all future demands, he collected all the accounts of old debts due by them to his father and himself, and presented these in part of payment. The people loudly exclaimed against this equitable procedure, and said that they were defrauded of the legacy; and when Herodes built the great stadium with this money, which had been intended for the encouragement of idleness and beggary, the people insisted, in derision, that it was called the Panathenæum, not in honour of the festival, but as having been built by *all the Athenians*.

This stratagem, though it savours of ingenuity, is by no means to be considered as dictated by selfish considerations. There never was a man, who had a more thorough contempt for the mere possession of riches than Herodes. The leading object of this celebrated character was, to benefit the public by his princely fortune; and this application of it certainly entitles him to a distinguished rank in the annals of his country. It was a remark of his own, that wealth not applied for the common good is but dead wealth; and that the chest of the miser is but a prison for riches. Those men who set so high a value on their money as to confine it to their coffers, he compared to the fanatics, who worshipped the god Mars, after having bound him. It was a noble maxim of this rich philosopher, that we ought to give, not only to relieve need, but also to prevent it. Boundless in his liberality to his friends and the necessitous, and influenced in his generosity by no paltry prejudice of language or country, it was his professed desire to accumulate treasure only in the affections of those around him, to promote learning and the arts, and to decorate the mighty empire to which he belonged. While other nobles were surrounded by musicians, players, and buffoons, the retinue of Herodes was composed of men of genius and learning, who found it their interest to court his notice. His public lectures, which he gave for the advantage of the youth, were numerous attended by people from all the neighbouring countries, and were well calculated to rouse the Athenians from that lethargy of genius into which they were now fallen. Some orations of his were still extant in the days of Suidas.

The encouragement which Herodes extended to men of literary pretensions exposed him occasionally to the arts of the designing. Aulus Gellius, who was one of his disciples and companions, relates one instance of this kind, which is much to the credit of his humanity. A man dressed in the style of a philosopher, wearing a cloak and a very long beard, presented himself to Herodes, and demanded some pecuniary assistance. On being asked who he was, the man replied, with indignant surprise, that he was a philosopher. "I see," observed Herodes, "the cloak and the beard; but I do not see the philosopher." When informed by one of the company that this was an impudent beggar, who was constantly teasing people for alms; "Well then," said Herodes, "let us give as men, though not as to a man."

The fame of Herodes chiefly rests now on his architectural works. His stadium, or race-course, on the banks of the Ilissus, which was four years in building, was the noblest work of the kind ever beheld. It was 630 feet long, 120 broad, and was constructed entirely of white marble. Mount Pentelion was nearly consumed to supply materials for this magnificent pile, which itself, according to Pausanias, seemed at a distance to be a white mountain. Upon the death of his wife Regilla, to which his enemies had the cruelty to accuse him of being accessory, he was thrown into the deepest sorrow; and to perpetuate her memory, he built a noble theatre at Athens, called after her name. This structure, according to Philostratus, exceeded in magnificence all the theatres in the Roman empire, being roofed with cedar, and adorned with all manner of statuary. Herodes, besides, adorned Corinth with a costly temple, dedicated to Apollo, a grand stadium at Delphi, built an aqueduct at Olympia in honour of Jupiter, repaired the Odeum of Pericles at Athens, erected baths at Thermopylæ for the use of the infirm, and, in short, decorated many cities in Italy, Greece, and Asia, with the most splendid and useful edifices. But the greatest of all his designs he unfortunately did not think it safe to execute. This was no less, than by cutting through the Isthmus, to unite the Corinthian and Saronic gulfs, and thus shorten the navigation on these coasts by 80 miles. He was heard to say, that this would be a monument which would discover to posterity the existence of a Max, and that while it remained unfinished, he had done nothing for his country. The magnitude, however, of the undertaking, to which the power of a Nero had not been adequate, deterred him from proposing it to the emperor, whose jealousy of his wealth and popularity might be productive of fatal consequences.

In his person, Herodes was of a gigantic stature, being, it is said, eight feet high, and strong and heavy in proportion. He wore but a small quantity of hair; his nose was aquiline; his eye brows were thick, and joined into one; his eye, which was remarkably lively, was at the same time full of sweetness and complacency. He had a son, who, like the sons of many other great men, was distinguished for nothing but idleness and vice. When a boy, he was exceedingly dull; and to make him learn, Herodes was obliged to keep in the house a living alphabet, consisting of four-and-twenty boys, each of whom went by the name of a particular letter. The philosopher had too much principle to entrust the whole of his wealth to such a fool.

The celebrity of Herodes Atticus, it is true, is owing chiefly to the accidental circumstance of being possessed of a great fortune. But if we reflect on the purposes to which he devoted that wealth; the liberality with which he relieved want; the encouragement which he gave to learning by example and munificence; the edifices which he reared in various parts of the empire for the important purposes of public splendour and convenience; he is fully entitled to a station in the temple of immortality. His example is an eternal satire on the conduct of all those men of rank and opulence, who, instead of consecrating a part of their superabundant affluence to the same elegant and useful pursuits, lay it out in the purchase of a few selfish sensations. He died at his family residence in Marathon at the age of 76, and was buried with great pomp at Athens. His funeral oration was pronounced, in a most feeling manner, by the philosopher Adrian, his disciple and friend, who, in recounting the eminent services of the deceased to his

country, drew tears from the eyes of all the Athenians. See Philostratus, *Sophistarum vite*, l. ii. c. 1. Suid. *Lexic.* *Aulus Gellius*, l. i. c. 2; l. ix. c. 2; l. xix. c. 12.

(E)

ATTICUS, TITUS POMPONIUS CÆCILIUS, was descended of one of the most ancient families in Rome. He was of the equestrian order; and whether we consider him as an intimate associate of the great, a prudent politician, or a dignified man of letters, he is one of the most honourable men that his country ever produced. He was born during the latter period of the republic: a time when the convulsions of a mighty state, now on the verge of dissolution, necessarily disclosed the real characters of men, and compelled the mind to exert to the utmost all the faculties bestowed upon it by nature. Hence it was, that, at this memorable period, there arose such a constellation of geniuses, both in arts and in arms, as the world in all probability will never again witness.

His father being distinguished for his attention both to his domestic affairs and to the study of letters, two of the greatest of human advantages, fortune and education, were thus secured to young Atticus. When yet a child, he is said to have discovered undoubted signs of natural talent. He is described as possessing, at that tender age, a most engaging manner, a quick apprehension, and a peculiar gracefulness of cadence and elocution; qualities which, while they commanded the respect of his companions, inspired them not a little with secret jealousy. It will give the reader a higher idea of the excellence of his parts than any description could produce, to be informed, that those youths, who were thus mortified at the superiority of Atticus, were L. Torquatus, the younger Marius, and the great orator Cicero. Such, however, were his gentleness and conciliating manner, that while he excited the juvenile emulation of his companions, he, at the same time, was their chief favourite, and retained their friendship to the end of life.

Having lost his father when young, and the civil commotions now beginning, between the parties of Cinna and Sylla, in which he had already lost an uncle, Atticus resolved, when yet a youth, to abandon, for a time, the scene of tumult and danger, and to retire with the greater part of his fortune to Athens, then the asylum of learning and refinement. Here, amid the groves of the Academy, he indulged the elegant propensities of his genius, and made such distinguished progress in his acquaintance with the Greek language, that he wrote and spoke it with the same propriety as a native. It was from this circumstance, together with his long residence at Athens, that he obtained the surname of Atticus, a designation of which he seems to have been proud, and that by which the children of his friends were taught to speak of him. Cicero ends one of his letters to him thus: *Κικέρων ὁ μικρὸς ἀπαζέται τὸν Ἀθηναῖον*: "The little Cicero salutes Titus the Athenian."

The amiable qualities of his heart soon endeared Atticus to the Athenian people. His deportment was such, that while accessible to the humblest, he lost nothing of his dignity, but was on a level with the highest. His prudence was so well known, that his advice was solicited by the magistrates; while his purse was open to all, and the poorest of the people hailed him as their benefactor. He frequently relieved the embarrassments of the state, by advancing large sums of money without interest; thus saving the public from falling into the hands of usurers and extortioners; and on some occasions he distributed among the people large quantities of

corn, with a liberality truly magnificent. Having continued for many years at Athens, dividing his time between the duties of his household, the pursuits of literature, the affairs of the city, and the interest of his friends, to many of whom he extended assistance when absent, he at last found the opportunity, which he had long desired, of returning to his native country.

On the return of tranquillity, accordingly, he took his departure from Athens. On this occasion, he received one of the finest compliments ever paid to a private individual; for the whole Athenian people assembled to witness his departure, and testified, by their tears, the genuine sorrow with which they were moved; and in his absence they did, what he had prevented with much difficulty while present; they erected statues in honour of him and his wife Pilia, in the most sacred parts of the city. This honour, it is probable, was not conferred on him till many years after his departure, since he was turned of 50 before he was married.

Thus loaded with the genuine honours of respect and gratitude, Atticus returned to enjoy the society of his early friends, who were now leading characters in the state. His school-fellow L. Torquatus was that year consul: Hortensius, his intimate friend, made a great figure as a public orator; as did also M. T. Cicero. It was difficult to say which of these two loved him most; and it is mentioned as a singular instance of his delicate management, that, though they frequently met in his company, these rival orators never gave vent to that acrimony of speech, which was natural to two angry competitors for public applause. His connection with Cicero was, if possible, rendered still more intimate by the marriage of Q. Cicero, the brother of the orator, with Pomponia the sister of Atticus. Of this match, which was brought about by Cicero, frequent mention is made in the letters of that orator to Atticus. These, consisting of sixteen books, are still extant; and for sprightliness of wit, accuracy of political information, and expressions of ardent and genuine friendship, they may be safely opposed to any epistolary collection in existence.

The paternal inheritance of Atticus was ample, though not splendid. But on the death of his uncle Q. Cæcilius, his fortune received a considerable accession. This old man was of a remarkably peevish disposition, inasmuch that few could bear his humour; but Atticus so won upon him by his dutiful attentions, that he adopted him as his son, and left him an inheritance of 10,000,000 sesterces, or near 100,000*l.* sterling. The unsettled state of affairs at home, and his long relegation at Athens, prevented him from marrying till considerably advanced in life. His wife's name was Pilia; but who she was, or what were her connections, no author has mentioned. By this marriage he had a daughter Pomponia, who was married to Agrippa, the favourite of Augustus: and his grand-daughter again by this marriage was betrothed by command of Augustus, almost as soon as she was born, to Tiberius, who was afterwards emperor. Nothing can be more decisive of the high consideration in which Atticus was held, and of his extensive though secret influence in the state, than this alliance into which he was pressed with the family of the Cæsars.

In his political life Atticus pursued a line of conduct which would not have been tolerated by the law of Solon; for in all the disturbances which took place at Rome during that eventful period, he so managed matters, that he was seldom implicated on either side. His friend-

ship for Cicero, it is true, induced him to violate this principle of neutrality to a certain extent; and he had no hesitation to declare himself openly against such a character as Catiline. But, in general, such was his attachment to peace and repose, that, even in his boyish days, nothing could prevail upon him to enlist under the banners of faction. This firm adherence to professed principle could not well be displeasing to either party; for though he should happen, as he sometimes did, to give private assistance to one, yet this was ascribed by the other to private friendship, and not to his approbation of political conduct. Hence it happened that Atticus was always courted by the two hostile factions at the same time. Thus, while he relieved the wants of the exiled Marius, he was at that very time caressed by Sylla. Though he furnished some of his private friends with money, who were devoted to Pompey's cause, yet Cæsar was so little displeased at this, that he applauded the neutrality of Atticus: and, after his victory at Pharsalia, while that conqueror made large demands on the rich citizens for money, he not only never molested Atticus, but, on his account, pardoned his nephew, who had carried arms against him.

Atticus was always a powerful advocate for moderation and humanity during that sanguinary period; and to this circumstance, no less than to his strict neutrality, we are to ascribe his wonderful success in preserving the good opinion of all parties. It was his constant maxim to alleviate, as much as in him lay, by his influence and money, the misfortunes of the sufferers, to whatever cause they were attached. Thus, though his strict intimacy with Cicero rendered him naturally favourable to the interest of Brutus, in opposition to Antony; yet, when Antony's affairs seemed utterly irretrievable, and his friends went over to the other side, Atticus interposed his good offices, and restrained Cicero and his coadjutors, not only from committing any violence on the person of Antony, but from persecuting his remaining adherents; whom he liberally supplied with whatever they required, out of his own pocket. Such, however, was the depravity of heart which influenced the proceedings of the triumvirate, that these services were not sufficient to prevent the name of Atticus from being inserted in the list of the proscribed. The fury of Antony raged to such a degree against Cicero, that he had resolved to extirpate from the face of the earth the orator and all his friends, without a single exception. But the tyrant prevailed upon to relent in favour of Atticus, who had retired into concealment: he wrote to him a letter with his own hand, inviting him to return, and sent a guard to escort him through the horrors of the night. It is a singular fact, that after Antony and Augustus quarrelled, Atticus continued to be their common friend: he frequently received letters from Antony, detailing his plans and operations in the East; while at the same time he maintained a daily correspondence with Augustus, who consulted him on the most important questions. The refined policy by which he conducted himself in this delicate predicament, almost justifies the eulogium of his panegyrist, when he says, that the history of Atticus has taught the world, "That man is fortunate or unfortunate, according to his own conduct."

The same prudence and forbearance, which prevented Atticus from taking any active part in the civil commotions of his time, prevented him also from availing himself of many opportunities of obtaining public offices.

The honour and emolument attached to these, he considered as completely counterbalanced by the cares and dangers from which they are inseparable in troublesome times. On more than one occasion, he might have obtained a province: but this he declined, as incompatible with that rule of political quiet which he had adopted. To this indolence he was also probably inclined from the maxims of the Epicurean philosophy, to which he professed an attachment. As pleasure, that is, virtuous enjoyment, together with the absence of pain and care, constituted the sole object of his desire, he would be disposed not to interfere in the angry contentions of the world; but rather, like the gods of Epicurus, to observe them, in dignified repose, at a distance. It is difficult to determine whether this political neutrality be altogether consistent with the interest which a good man ought to take in the welfare of his country. But the truth is, that the Roman empire at that time had extended itself over so many kingdoms and provinces, that the proper idea of country was in a great measure lost, and the feelings of patriotism, which are ever most ardent in a small state, could there have scarcely been excited.

In his domestic capacity, Atticus was equally interesting. He was remarkably assiduous in the management of his private affairs, taking charge not only of his own, but of those of Cicero, Marius, Hortensius, Cato, and others. Though his revenue was considerable, his expenses were extremely moderate. He had no magnificent equipage, nor costly villa; in all things he was partial to the simplicity of the ancients, whose manners he had thoroughly studied. His house, which stood on the Quirinal hill, was a plain old edifice; though at the same time abundant, convenient, and suitable to his equestrian rank: and here every thing was equally remote from meanness and ostentation. Splendid occasionally in his hospitality, and entertaining, as he did, men of the most exalted condition, such as Cicero, Cæsar, Antony, and Augustus; still there was displayed more politeness than magnificence; more neatness than show. It was his peculiar praise, that of all his household, there was none who was not born under his own roof; and every person, to the meanest lacquey, was a proficient in the valuable arts of reading and writing. His feasts were never attended by bands of music, nor accompanied by any sumptuous exhibitions, such as were agreeable to the gross taste of most of his contemporaries. The only vocal entertainment allowed by him on these occasions was *reading*, which was performed by persons trained for the purpose; and this rational amusement communicated the most lively pleasure to the guests, who, he took care, were always of the same taste with himself. What must have been the elegance of the remarks, and the interest of the whole amusement, when the company consisted of Atticus, Cicero, Cæsar, the poet Callidius, Sallust, Hortensius, Cornelius Nepos, and similar men of letters!

In conversation, Atticus was so fascinating, that young men preferred his company to that of their own equals: but in his gayest moments, he had such a regard for decorum, that, when even in jest, he had an air of dignity and elevation; so that it was uncertain whether he was more beloved or respected by his friends. Enviably talented! which could thus temper the suavity of the companion with the dignity of the instructor; which could insensibly charm the levity of youth into the chastened majesty of philosophy!

In his attachment to his friends, Atticus possessed the utmost steadiness, and, unlike many a pretended patron, when he once made a promise, he considered the whole business as his own till he performed it. His economical style of living enabled him to indulge the generous dispositions of his heart to a much greater extent than most could afford, who even surpassed him in wealth. Money was not his object, but the luxury of bestowing it well; and this he often did in the noblest manner. When Brutus was in the plenitude of his power, Atticus refused to support him; but his fortunes were no sooner broken, than he relieved his private necessity by a princely donation. To Cicero, when stript of his possessions, and driven into exile, his faithful friend sent a sum of money in his distress, amounting to 200*l.* sterling. Of his filial and fraternal affection, we may judge, from the funeral oration pronounced by him, at the age of 63, over his mother, whom he buried in her 90th year. He there declared, that he never in his life had occasion to be reconciled to his mother, nor had ever any quarrel with his sister, who was then much of his own age. Mr Bayle is pleased to be witty on this declaration, regretting that the orator said nothing about his wife Pilla, whom he therefore suspects of having been on bad terms with her husband. But Mr Bayle ought to recollect that he had not then been long married, whereas he had all his life maintained a close intercourse with those to whom he paid so elegant a compliment.

Atticus made a considerable figure in his own time as a writer. He kept up an epistolary correspondence with the most eminent characters of that period. Of his correspondence with Cicero, we have a lasting monument in the letters which he received from that orator. He wrote a book of historical antiquities, into which he introduced genealogical tables of the principal families in Rome. He also composed, in Greek, an account of the consulship of Cicero, with which the latter declared himself to be well pleased, only that the style appeared somewhat unpolished and unadorned. Nor did Atticus altogether neglect poetry, which he cultivated principally for the elegant taste which that study promotes. His chief effort in this way consisted in describing, under their pictures, the most remarkable actions of distinguished men, concerning whom he is said to have comprised an amazing quantity of information in the compass of four or five verses.

The constitution of Atticus was excellent, since, for thirty years together, previously to his last illness, he had no occasion for a physician; and though now in the seventy-seventh year of his age, he was apparently as stout and hale as ever. About this time he was seized with a distemper which affected his intestines, and at last broke out into a sore; upon which, dreading a long continuance of pain, and supposing his fate to be inevitable, he resolved to anticipate nature by abstaining from food. Having sent for his son-in-law, Agrippa, and some more of his friends, he declared to them his fixed resolution, and requested that none of them would endeavour to dissuade him from it. He is said to have done all this with such a composed countenance, that he seemed to be only talking of passing from one house to another, and not from this world to the next. At the end of two days the pain and fever sensibly abated; but thinking it beneath him to recede from his purpose, he persisted in his abstinence, and on the fifth day after he had made the fatal resolution he breathed his last. Thus

died Atticus the death of a Roman: that is, he shrunk from a temporary distress with a meanness unbecoming a man, and rushed into the other world before he was regularly summoned. But this presumption we must ascribe, in this instance, to the prejudices of the time, rather than to the individual. How different his conduct from that of a man, in similar circumstances, who has been styled the modern Atticus! "See," said Addison to his friends, probably in allusion to this very suicide of Atticus, "see now a *Christian* can die." Atticus was buried, according to his own request, without any funeral pomp, by the Appian way, in the tomb of his uncle Cæcilius.

Upon the whole, the most prominent feature in the character of Atticus, so far as it is known to us, was prudence. But we must avow our regret, that the piece ascribed to Cornelius Nepos should be the principal source of our information. That life is evidently intended for a panegyric, in which every thing great and amiable is ascribed to Atticus, without a single shade of failing, to the best of the writer's judgment. Atticus, however, was unquestionably a man of first rate consequence in his own time. His strict intimacy with that crafty tyrant Augustus, who was forward in marrying his nephew Tiberius to Agrippina, the granddaughter of Atticus, is alone a full proof that he was an elevated character. The Epistles of Cicero, too, written when that orator and statesman was in the plenitude of his fame and power, breathe such an air of ardent friendship, unlimited confidence, and even anxious respect, that we cannot but conclude, independently of Nepos, that Atticus was a politician of first rate accomplishments, wealth, and influence. We say *politician*, for though he disclaimed the title, nothing can be more evident from the epistles of Cicero, than that Atticus had a very considerable share in the secret movements of the political machine, and that he at least sanctioned, if not suggested, a considerable degree of stratagem and intrigue for the accomplishment of his purposes. These, however, it must be confessed, were all of a gentle and amiable kind; and he seems to have been one of those few, who rigidly shaped their conduct by the precepts of philosophy. This love of privacy was not the effect of timidity or indifference; it was founded on a settled plan of avoiding the troubles of the time, on the score of ultimate happiness. Atticus was splendid with economy; industrious with dignity; and his purse was open to relieve the wants of contending leaders, not because he had no public principle, but because these were his private friends, and were, perhaps, in his secret opinion, all equally devoid of patriotic motives. When two corrupt factions contended for the superiority, what wise man would join either, or make either his enemies? In short, Atticus was one of those humane conciliating characters, who diminish the animosity of parties, and who, if more numerous, would entirely suppress it. The intrinsic value of his mind is the only foundation of his fame. Without having performed a single splendid action, or discharged any public function, or aimed at exciting the admiration of posterity by any remarkable monument of his taste, talents, or munificence, he has the singular felicity of being famous for ever on account of his mere personal worth! See M. T. Ciceronis *Epistolæ ad Atticum*; *Vita T. Pomponii Attici ex Cornelio Nepote*; Suetonii *Vita Tiberii*, c. 7.; Gassendi, *Vita Epicuri*; *Dict. de Bayle*. (E)

ATTILA, the son of Mundzuk, king of the Huns.

ATTILA.

In conjunction with his brother Bleda, he succeeded to the supreme government of the Huns about the year 433. Bleda, however, was soon deprived of his government and his life by the cruel policy of his brother. Attila, according to the account of Jornandes, the Gothic historian, exhibited in his person and features the complete portrait of a modern Calmuc; having a large head, a swarthy complexion, small deep-seated eyes, a flat nose, a few hairs in the place of a beard, broad shoulders, and a short square body, of nervous strength, though of disproportionate form. With this vulgar figure, which, however, might be fashioned according to the most refined ideas of personal beauty among the Huns, he affected the haughty step and the commanding look of majesty. He had a way of rolling his eyes in savage fierceness, for the purpose of inspiring fear or reverence into the minds of beholders. This could not fail to produce its effect: It is easy for a despot to stare his trembling slaves out of countenance; and the barbarian princes, who confessed that they could not gaze with a steady eye on the divine majesty of the king of the Huns, were at least as sincere in their adulation as the servile flatterers of Augustus, who pretended to shrink from the lustre of his piercing eye. Attila delighted in war, but his policy was not inferior to his prowess: and he dexterously called in the aid of superstition, to assist him in establishing a power which made him the terror of the world, and, from the way in which it was exercised, acquired for him the title of *the scourge of God*. So far from considering this designation as any disgrace, he is said to have adopted it himself, as one of his titles of honour. A fortunate occurrence, or a well-concerted plot, seemed to mark him out as the favourite of heaven, and the destined conqueror of the world. The Scythians were accustomed to worship an iron scymitar, as the symbol of Mars; and the very sword of the god himself, together with the power which it conveyed, were supposed to be committed into the hand of Attila. A shepherd of the Huns, perceiving one of the heifers to be wounded in the foot, followed the track of blood, till he discovered the point of a sword among the long grass; having carefully dug it up, he presented it to Attila, who joyfully accepted it as the property of the god of war, and as a pledge of his future victories.

The empire of Attila was of immense extent: those vast tracts of country anciently comprehended under the names of Scythia and Germany were subject to his controul; so that his dominions extended from the Danube on the one hand, almost to the confines of China on the other. He could, with ease, bring into the field an army of 500,000, or, according to others, of 700,000 men. This immense force was never suffered to remain long idle. On a frivolous pretence he invaded the eastern empire, which was at that time governed by the feeble hand of Theodosius. He swept every thing before him like a desolating inundation, and rolled the tide of carnage to the very gates of Constantinople. A historian of those times describes his progress, in language which strongly expresses the extensive and absolute devastation which every where marked his steps: *Pene totam Europam, invasit excisisque civitatibus atque castellis, conrusit*. Attila himself used to say, that the grass never grew where his horse trod. The fear, or the policy, of the western Romans had induced them to leave the eastern empire to its fate. Theodosius, being thus without any resources to oppose this formidable invader, was glad

to accept such a peace from him as he chose to dictate. The terms, of course, were sufficiently humiliating. The conqueror demanded a large tract of territory stretching along the southern banks of the Danube, from Singidunum, or Belgrade, as far as Novæ in Thrace: the breadth was defined by the vague computation of fifteen days journey. In the next place, the tribute or subsidy, paid by the emperor, was to be raised from 700 pounds of gold to upwards of 2000; and an immediate contribution was to be paid, to defray the expenses of the war: And lastly, all the Huns who had been taken in war were to be delivered immediately without ransom, whilst the Roman prisoners were obliged to purchase their freedom at the price of twelve pieces of gold for each man. This ignominious treaty was gladly subscribed by the emperor, who had no alternative between it and utter destruction. There was also another circumstance, which, though less hurtful to the public, was not less humiliating to the degenerate Romans of the East. When any of Attila's officers took a fancy to have a wealthy or beautiful wife, Theodosius was obliged to provide one, and thus to secure a temporary tranquillity by the sacrifice of private feelings.

Attila was continually harassing Theodosius with unwelcome embassies; and as the barbarian was extremely jealous of his consequence, the emperor was forced to make a suitable return; and the pride of Attila was not easily satisfied with the dignity of the persons who approached him in quality of ambassadors. At last Maximin, a principal person at the court of Constantinople, accepted with reluctance of the troublesome commission of reconciling the angry spirit of the king of the Huns. Priscus the historian accompanied him, and had an opportunity of making many curious observations on the singular manners of this formidable monarch, and of his barbarian subjects. The ambassadors of Theodosius proceeded, by toilsome journeys, through countries depopulated by the ravages of the Huns, and covered with the bones of the slain. Having passed the hills of modern Servia, and crossed the Danube in canoes provided by the barbarians, they halted at no great distance from the camp of Attila. They were now continually exposed to the insolence and the caprice of the haughty conqueror. The ministers of Attila pressed Maximin to communicate the business and the instructions which he reserved for the ear of their master; and on his refusal to comply, he was commanded instantly to depart; the order was recalled; it was again repeated; and at last, when it was found impossible to subdue the patient firmness of Maximin, he was admitted into the royal presence; but, instead of obtaining a decisive answer, he was compelled to undertake a remote journey towards the north, that Attila might enjoy the satisfaction of receiving in the same camp the ambassadors both of the eastern and western empire. During this journey the wants of the ambassadors were plentifully supplied by the Huns, though the fare was very different from the luxuries of Constantinople. They had mead instead of wine; millet in place of bread; and for drink, they had a certain liquor, which, according to Priscus, was distilled from barley. Having met with a disaster in the night-time, in consequence of a violent storm, they were kindly relieved by the barbarians, who were awakened by their cries. The widow of Bleda, Attila's brother, was particularly attentive on this occasion, and added to her other favours the gift, or at least the loan of a sufficient number of beautiful and obsequious damsels

At last, after a fatiguing and harassing journey, they reached the capital of an empire, which for several thousand miles did not contain a single city. This capital seems to have been situated in Upper Hungary, between the Danube, the Teys, and the Carpathian hills. It could not boast of a single stone building, except some baths, which had been lately constructed. The houses of the principal officers were all built of timber; and the palace of Attila, the most magnificent building in his dominions, was composed of the same material. This palace was enclosed by a lofty wall, or palisade, of smooth square timber, intersected with high towers, but intended for ornament rather than use. Within this wall was a separate house for each of the numerous wives of Attila; and, instead of the rigid confinement imposed by Asiatic jealousy, they politely admitted the Roman ambassadors to their presence, their table, and even to the freedom of an innocent embrace. The Huns, though meanly lodged, were fond of displaying those riches which were the fruit and evidence of their victories; accordingly, the trappings of their horses, their swords, and their shoes, were studded with gold and precious stones; and their tables were profusely spread with plates, and goblets, and vases, of gold and silver, the work of Grecian artists. Attila alone assumed the superior pride of despising finery, and of adhering to the simplicity of Scythian manners: his dress, his arms, and the furniture of his horse, were plain, without ornament, and of a single colour; his table was served in wooden cups and platters; flesh was his only food; and he never tasted the luxury of bread.

Maximin was placed in a most perilous situation by the perfidy of his countrymen. He was ignorant that a conspiracy had been formed against the life of Attila; and that Vigilius, interpreter to the embassy, actually carried along with him a weighty purse of gold, to reward the services of the person who should destroy the king of the Huns. Attila, however, was fully apprised of every particular, by the confession of the person who had engaged to perform the service; and, therefore, instead of being surprised at the haughtiness and rudeness with which he treated the ambassadors, we have more reason to admire his magnanimity, in respecting the rights of hospitality, and in admitting into his presence the ministers of a prince, who had basely conspired against his life. Vigilius was instantly seized; and was forced to make a full discovery of the whole transaction. Attila spared his life; and, under the name of ransom, accepted of two hundred pounds of gold for the life of a traitor, whom he disdained to punish. He immediately dispatched ambassadors to Constantinople, to denounce vengeance against Theodosius, and to demand the head of Chrysaphius the eunuch, who had been the chief agent in the business. None of his demands could be denied. A solemn embassy was again sent to deprecate his wrath: and he condescended to pardon the emperor, the eunuch, and the interpreter.

Upon the death of Theodosius, Marcian, his successor, peremptorily refused to pay to Attila the accustomed tribute: and instructed his ambassador Appolonius to signify this refusal, in the very camp of the Huns. Attila, enraged, sent an equal defiance to the courts of Ravenna and Constantinople: and his ambassadors addressed both the emperors in the same haughty language. "Attila, my lord and thy lord, commands thee to provide a palace for his immediate reception." Despising the eastern Romans, whom he had so often van-

quished, he directed all his strength against the western empire. The nations from the Wolga to the Danube obeyed his summons, and poured their countless myriads on the devoted country of Gaul. The Roman empire was saved, on this occasion, by the policy and intrepidity of Ætius, whom Gibbon calls the last of the Romans. He formed a strict alliance with Theodoric, king of the Visigoths, who at that time reigned at Thoulouse: and, in conjunction with his warlike forces, boldly proceeded to meet the terror of Europe and of Asia on the plains of Chalons. Here a tremendous engagement took place. The centre of the Visigoths soon gave way, owing to the defection of some of their allies; Theodoric, their king, was slain whilst animating his men to battle; and Attila already began to exult in the confidence of victory. In this situation, Torismond, the son of Theodoric, who had occupied a rising ground, rushed down upon the Huns with irresistible fury: the Visigoths soon restored their order of battle, and Attila for the first time sustained a defeat. The number of slain, on this occasion, according to the lowest accounts, amounted to 162,000, whilst others swell it to nearly double that number.

The policy of Ætius probably saved the Huns from utter destruction: he saw that the empire had as much to fear from the victorious Goths, as from the Huns whom they had vanquished: he therefore persuaded Torismond, who was bent on revenging the death of his father, to return to Thoulouse, that he might disappoint the ambitious designs of his brothers. By this device, Attila was permitted to retire unmolested, and to recruit his forces for an invasion of Italy in the ensuing spring. He scarcely met with resistance but at Aquileia, which made a long and obstinate defence, but was at last taken and destroyed. Italy was completely at his mercy, when the feeble Valentinian resolved to try the effect of a supplicatory embassy. Avienus, a person of the highest dignity, and Leo, bishop of Rome, undertook the dangerous office of deprecating the wrath of the enraged barbarian: and the eloquence, majestic appearance, and sacerdotal robes of the bishop, had the same effect on Attila, that the appearance of the Jewish high priest is said to have had on the mind of Alexander. The safety of Italy was procured by the eloquence of the ambassadors, and the immense dowry of the princess Honoria. The empire was soon after freed from the fear of this formidable invader. Having added a beautiful maid to the list of his innumerable wives, the marriage was celebrated with barbaric pomp, at his wooden palace beyond the Danube. The monarch retired, at a late hour, to the nuptial bed, oppressed with wine. His attendants continued to respect his pleasures, or his repose, the greatest part of the ensuing day; till the unusual silence alarmed their fears and their suspicions; and, after attempting to awake Attila by loud and repeated cries, they at length broke into the royal apartment. They found the trembling bride sitting by the bedside, hiding her face with her veil, and lamenting her own danger and the death of the king, who had expired during the night. An artery had suddenly burst; and, as Attila lay in a supine posture, he was suffocated by a torrent of blood. It was reported at Constantinople, that on the fortunate night, in which he expired, Marcian beheld in a dream the bow of Attila broken asunder: and the report, says Gibbon, may be allowed to prove how seldom the image of that formidable barbarian was absent from the mind of a Roman emperor.

The authentic materials for the history of Attila may be found in Jornandes, (*de Rebus Geticis*), and Priscus, (*Excerpta de Legationibus*.) See these materials collected by Gibbon in the last volume of his History. (g)

ATTOCK, a city and fortress of Hindostan, built on the site of the ancient *Taxila*, by Acbar, in 1581. It stands on the eastern bank of the Indus, and commands the narrow pass from Cabul to Lahore. E. Long. 71° 12', N. Lat. 33° 6'. (j)

ATTORNEY, (*Attornatus**) signifies one who is appointed by another to transact any business for him in his absence. An attorney is either public,—as those in the courts of record,—and is constituted by warrant from his client; or private,—to perform any particular act or piece of business,—who is usually appointed by *letter of attorney*. (z)

ATTORNEY AT LAW, is a person who manages the law business of another, by whom he is retained; the term being analogous to the procurator, or proctor, of the civilians and canonists.†

* From the word *Attornatus* being thus placed between parentheses after the principal word *Attorney*, one would be led to suppose that the former was a classical Latin term, from which the latter was derived, whereas it is in fact nothing else than the *latino maccheronico* of the common law. When all law proceedings in England were enrolled in the Latin tongue, Latin words were sometimes necessarily, and sometimes unnecessarily, coined for the use of the attorneys, who, in general, were not eminent classical scholars. In this, however, the lawyers of England were not singular, for the use of *dog-latin* in law proceedings and in legal treatises appears to have been common at a certain period all over Europe. Witness the words *assecuratio* (insurance), *cambium* (exchange), *girare* (to draw), *girator* (the drawer of a bill of exchange) which appear so often employed in the works of the Italian and other foreign writers on mercantile law. And in some old French records it is said that the plaintiff *debottatus fuit*, meaning that he was *debouté*, or non suited. DU PONCEAU.

† In the United States attorneys at law are appointed as in England by the courts of justice, and can only practice in those courts in which they have been admitted. In order to entitle a candidate to admission, he must have served a regular clerkship in the office of a practising attorney during the time prescribed by the law of the state, or, where the state has not legislated on the subject, by the rules of the court, which time varies in the different states, and is in general from three to five years. But he needs not, as in England, have been articled by indenture; the *student*, as with us he is called, enters freely into a lawyer's office, in order to acquire the necessary knowledge to entitle himself to become a member of the profession, and may as freely leave it. At the expiration of his term of probation, he undergoes an examination, by professional men appointed by the court for that purpose, and if they report him qualified, and he produces a certificate of his good moral character, he is admitted to practice as an *Attorney and Counsellor* at law. For, in most of the states, if not in all, the two professions are blended in one, and are not exercised by different persons, as in Europe. It was attempted, on the first establishment of the federal government, to separate the two professions of attorney and counsellor in the supreme court of the United States;

VOL. III. PART I.

Anciently, (according to the old Gothic constitution) every suitor was obliged to appear and prosecute or defend his suit in person, unless by special license from the king; and this still continues to be the rule in criminal cases. But by sundry old statutes, from that of Westm. 2. c. 10., permission was granted for attorneys to prosecute or defend any civil suit in the absence of the parties. An idiot, however, cannot, at this day, prosecute or defend by attorney, but must appear in person.

Attornies are admitted to the execution of their office by the superior courts of Westminster-hall. They are considered as officers of the respective courts in which they are admitted; on which account they enjoy many privileges; and are, on the other hand, peculiarly subject to the censure and animadversion of the judges. In order to enable one to practice as an attorney in any of these courts, he must be admitted and sworn an attorney of that particular court; and an attorney in the King's Bench cannot practise in the Common Pleas, nor *vice versa*. To practise in the Court of Chancery, it is also necessary to be admitted a solicitor therein.

There are divers statutes which regulate the admission, &c. of attorneys; as, 3 Jac. I. c. 7; 12 Geo. I. c. 29; 2 Geo. II. c. 23; 23 Geo. II. c. 46; 25 Geo. II. c. 26, &c.

Besides the obligation of fidelity to his client, the attorney owes him diligence and secrecy; and, in certain

but the experiment did not succeed. In the state of New York, however, a young gentleman must, as we are informed, have practised a certain number of years as an attorney, before he can be admitted to plead as an advocate; but it must be observed, that it is the only State, except, perhaps, South Carolina, in which the formal written pleadings in causes are carried on with any considerable degree of regularity, and the fees being in general adequate to the labour required (which is not the case in other states, where the attorney's fees are excessively trifling) the young practitioner may, by managing only the formal parts of causes, acquire experience in his profession, and at the same time reap a reasonable profit, while the elder counsellor, not being diverted from his more important avocations by the dry details of mere mechanical practice, is enabled to give a more undivided attention to the nobler branches of his profession.

In the states where it is otherwise ordered, that is to say, almost throughout the United States, suits are carried on with very little attention to mere form, and hardly any thing more is expected from the attorney than to file a declaration at a certain stage of the cause. In some states, such as North Carolina, the parties go often to trial without even a declaration; pleas are entered in the record in a few words, *non assumpsit, non cul,* &c. without ever being drawn at length, and the writs are prepared by the clerks of the respective courts. It is very seldom, indeed, that a special plea or replication is filed in any cause.

The legislature of Pennsylvania some time ago attempted to substitute for a declaration, a plain *statement of facts*, to be drawn up and filed without regard to the established forms. But the practitioners have found it more convenient to adhere to ancient precedents, and the practice of filing *statements*, after being partially tried for a short time, has fallen into disuse.

DU PONCEAU.

cases, a tior lies, at the suit of the client, against his attorney, for neglect of duty. Blakst. *Comment.* b. iii. ch. 2. *Jacob's Law Dict.*

In Scotland there is no class of law practitioners who take the name of attorneys. The office there is not public, as in England, but private; and it is constituted by letters of attorney. The person who receives infetment for another is also called the attorney. See *Bell's Dict. of the Law of Scotland.* (z)

ATTORNEY GENERAL, is the name given to a great law officer, and principal counsel for the crown, who is constituted such by the king's letters patent. His duty is to exhibit informations, and prosecute for the crown in matters criminal; and to file bills in the exchequer, for any thing which concerns the king in inheritance and profits. See *Jacob's Law Dict.* (z)*

ATTORNMENT, or **ATTOURNMENT**, *Attornamentum*, from the Fr. *Tourner*;) in the law of England, signifies the tenant's acknowledgment of a new lord, in the sale of lands, &c.

This practice derives its origin from the nature of feudal tenures, and from the spirit of feudal customs. For, as by that system it was held to be neither reasonable nor proper, that a feudatory should transfer his lord's gift to another, and substitute a new tenant, without the consent of the lord; neither, on the other hand, was it deemed allowable for a lord to alienate his seignory without the consent of his tenant, which consent was called an *attornment*. And the doctrine of attorn-

ment was afterwards extended to all lessees for life or years.

In the course of time, however, the necessity of attornment was modified and restricted by the statute *Quia emptores terrarum*, (18 Edw. I. stat. 1.); the statute of *uses* (27 Hen. VIII. c. 10.), and by the statute of *wills* (34 & 35 Hen. VIII. c. 5.) At length, both the necessity and efficacy of attornments were almost entirely taken away by the statute 4 and 5 Ann. c. 16, which enacts, that all grants and conveyances of manors, lands, rents, and reversions, &c. by fine or otherwise, shall be good, without the attornment of the tenants. And by the statute 11 Geo. II. c. 19. attornments of lands, &c. made by tenants to strangers claiming title to the estate of their landlords shall be null and void, and shall not affect their landlord's possession. This, however, shall not extend to annul any attornment made pursuant to a judgment at law, or with consent of the landlord; or to a mortgage on a forfeited mortgage.

Since the passing of these statutes, the doctrine of attornment,—which formerly was one of the most copious and abstruse in the law,—may be considered as almost entirely obsolete and useless. See *Jacob's Law Dict.* (z)

ATTRACTION, CHEMICAL, usually called **AFFINITY**, an attraction which exists between the minute particles of matter, which urges them together, and which keeps them united. It acts only at insensible distances, and becomes imperceptible when the distances between bodies is sensible. Hence we have no means of knowing the rate according to which it varies. Some philosophers have endeavoured to prove that it is merely a case of gravitation, and of course that it is inversely as the square of the distance; but the most cautious and best informed philosophers have inclined to the opinion, that it follows a different law, varying as $\frac{1}{d^3}$, or even according to some higher power. This in particular was the opinion of Sir Isaac Newton.

The opinion at present entertained by chemists is, that the affinity between bodies varies in intensity according to the body; for example, that the affinity between sulphuric acid and barytes is not the same in point of force, as the affinity between sulphuric acid and potash. This opinion is founded on a well known fact, that if sulphuric acid be in combination with potash, if we mix barytes with the compound, the acid leaves the potash and unites with the barytes. Hence it was inferred, that sulphuric acid has a stronger affinity for barytes than it has for pot ash. On similar experiments the proportional strength of the affinity of various bodies for each other was founded, and the results were drawn up into tables, which were considered as denoting the strength of the affinity of different bodies for each other. Berthollet has lately shewn, that these decompositions are much more complicated than had been suspected, that they are never complete, and that they may be explained upon other principles. He has endeavoured to shew, that affinity in all cases produces combinations, and never decompositions; and that the decompositions which take place are owing to other circumstances, many of which he has enumerated. If this notion, which is at least plausible, be well founded, it destroys the whole doctrine of elective attractions. Berthollet has pointed out another method of determining the strength of affinity of various bodies for each other. According to him, that body, the least weight of which is capable of neutralizing an acid, has the greatest affinity for that acid.

* In the United States there is an attorney general appointed by the president for the whole Union, who is styled *Attorney General of the United States*. He is bound to reside at the seat of the general government, and his duty is to prosecute and conduct all suits in the supreme court in which the United States are concerned, and to give his advice and opinion upon questions of law, when required by the president, or when requested by the heads of departments. There is also a district attorney, appointed by the president in each of the States and Territories, (which for the purposes of the federal government are called *Districts*), whose duty it is to prosecute in their respective districts all delinquents for crimes and offences cognizable under the authority of the United States, and all civil actions in which the United States are concerned, except before the Supreme court, in the district in which that court is holden. There is no solicitor general nor other law officer attached to the government of the Union.

There is also an attorney general appointed in each state by the executives thereof to prosecute public offences, and manage the concerns of their state in courts of justice. They are bound also to give advice to the state government, when required. In most of the states the attorney general appoints deputies to manage his business in the different counties into which each state is divided. In the state of New York, there are, besides the attorney general, district attorneys, appointed by the executive on the model of the federal government, each of whom exercises the duties of his office in a certain number of counties, which are formed for that purpose into a district. We do not know of a *solicitor general* being appointed in any of the states, except in *North Carolina*, where there is an officer of this latter denomination, and also an attorney general.

DU PONCEAU.

Thus, of all the bases capable of combining with sulphuric acid, the least weight of ammonia is capable of neutralizing a given quantity of the acid, while the greatest weight of barytes is required. According to this doctrine, ammonia has the strongest affinity, and barytes the weakest affinity of all the bases for sulphuric acid. This opinion seems at first sight plausible, but its plausibility depends upon the indefinite meaning attached to the word *neutralize*. The truth is, that at present we have no means whatever of determining either the intensity or the variation of the force called affinity, and know only that it exists, and that it is very strong.

Mr Davy has lately added a new and very curious fact respecting compounds. He has shewn, that when two particles are united, they are in different states of electricity, the one positive and the other negative, and that the difficulty of decomposing them depends upon the intensity of these states. Oxygen and acids are always negative; hydrogen, and alkalis, and earths, always positive. If, by means of electricity, we bring them into the same electrical state, as by making them both positive, or both negative, then they instantly separate from each other, and the compound is decomposed. By this contrivance, he decomposed the alkalis and earths, and several of the acids and metallic oxides. Hence it is not unlikely that chymical affinity and electrical attractions may in reality be one and the same force. The subject is still involved in obscurity; but we may expect much elucidation from the skill and industry of the philosophers at present engaged in the investigation.

Mr Dalton has lately thrown out a very ingenious idea respecting chymical affinity, which deserves to be mentioned. According to him, bodies unite either atom to atom, or two or three atoms of one to one atom of another. Thus water is composed of an atom of oxygen and an atom of hydrogen united together; ammonia of an atom of hydrogen and an atom of azote united together; carbonic acid of two atoms of oxygen united to one of carbon. Sulphate of potash consists of a particle of sulphuric acid united to a particle of potash; supersulphate of potash of a particle of potash united to two particles of sulphuric acid. If we admit that matter is composed of atoms, as is at least probable, it is difficult to refuse admission to this hypothesis, though it is probable that more complicated cases may exist. For example, two atoms of one body may combine with three of another, and so on. It is even possible that the proportion in which bodies unite cannot always be represented by numbers. But this hypothesis of Dalton is much more probable, and corresponds much better with the phenomena, than the opposite one of Berthollet, that bodies combine in all proportions whatever. Dalton's hypothesis is very useful, because it facilitates the knowledge of the composition of bodies. For example, if water be composed of an atom of hydrogen and an atom of oxygen, it follows, from the known analysis of water, that the weight of an atom of hydrogen is to that of an atom of oxygen as 1 to 6. Hence we know, that when oxygen enters into a combination, it will always enter as 6, or as some multiple of 6. This is very observable in the metallic oxides. The quantity of oxygen in the second oxide is usually double that in the first oxide, and that in the third triple that in the first. The same thing is equally remarkable in the salts; the supersulphate of potash contains just double the quantity of sulphuric acid that exists in the sulphate, and all the supersalts contain twice as much acid as the neutral salts.

with the same acid and base. The atomic theory of Mr Dalton, plausible as it is, will be overturned, if Mr Davy succeeds in proving that azote is a compound of oxygen and hydrogen, as his experiments already published give us some reason to suspect. (c)

ATTRACTION, PHYSICAL, comprehends the attraction of gravity, electricity, and magnetism, and that which is exerted upon light in its transmission through diaphanous bodies, or in its passage near those which are opaque. The theory of gravitation has already been fully discussed under the head of PHYSICAL ASTRONOMY, and the other kinds of attraction shall be treated of at full length under the articles to which they more particularly belong. It may be proper, however, to state in general, that the attraction of electrical and magnetic substances, like those of the planetary bodies, seems to follow the law of the inverse ratio of the squares of the distances. This has been ascertained by the accurate experiments made with a torsion balance by the celebrated Coulomb; and we are surprised to see it stated in some of the foreign journals, that M. Simon of Berlin, by means of a balance made entirely of glass, has found the law of electrical action to be in the simple inverse ratio of the distance. As the apparatus which he used is said to have been less sensible than the torsion balance used by Coulomb, we are not disposed to put any confidence in this new result.

There is no method of ascertaining the law of the attractive force, by which the rays of light are refracted in their passage through transparent media; and it is almost equally difficult to determine the rate of its variation when the luminous particles are inflected by passing near opaque bodies. From some experiments, however, we are led to conclude, that the ultimate effects produced by the inflecting body upon a row of particles, placed at different distances from it, are in the simple inverse ratio of the distances.

It has been much disputed among philosophers, as has been already remarked in the preceding article, whether the attraction of affinity is merely a case of universal gravitation, or depends on some separate cause, and follows a different law. The first of these opinions has been maintained by Buffon, Libes, and we may perhaps add La Place. The last is the opinion of Newton, and has been adopted by most of his followers. We shall endeavour to give a short view of the reasoning that has been employed on both sides of the question.

In the chapter in *Physical Astronomy* on the Gravitation to a Sphere, we have shewn, that when the law of the attracting force varies in the inverse ratio of the square of the distance, the total attraction of a sphere upon a particle, situated at any distance from it whatever, is the same as if all the attracting particles had been concentrated in the centre of the spherical body. Considering spheres as simple gravitating points, it is obvious, that the attraction of a sphere, upon a point in contact with it, can never be infinitely great, when compared with the attraction which it experiences when out of contact; for the radius of the sphere, which is in this case a measure of the attraction, must always have a finite ratio to the distance of the particle when out of contact.

When the attracting force varies as the cube of the distance, or according to any higher ratio, it has been shewn by Newton, (see the following article on the ATTRACTION of Solids,) that the attraction of the sphere is indefinitely greater when the particle is in contact than

when it is placed at any finite distance. This result, which is conformable to the phenomena of chemical attraction, induced Newton to believe, that the law of the force was in the inverse ratio of the cube of the distance, or perhaps some higher power of the distance.

M. Libes has maintained, that when the law of the force is inversely in the duplicate ratio of the distance, the action of a sphere upon a particle in contact with it is not proportional to the radius of the sphere. "When the elementary molecule," he observes, "is placed on the surface of the sphere, it is in contact with one of the molecules of the solid, whose action is $= \infty$. The molecule of the sphere, situated at the opposite extremity of the same diameter, exerts upon the molecule attracted a force $= \frac{1}{\infty}$. Whence the two molecules of

the sphere, of which one touches the attracted molecule, and the other is situated at the opposite extremity of the same diameter, do not attract the molecule in the same manner as they would do if they were united in the centre of the sphere; and, consequently, the action of a sphere upon an elementary molecule which it touches is not proportional to the radius. If the masses of two finite bodies which attract each other become infinitely small, their mutual action, in so far as their masses are concerned, will suffer an infinite diminution. But if these masses, which have become infinitely small, are in contact, their centres of action will be infinitely near each other, whence the attraction, when it follows the inverse ratio of the square of the distance, will be augmented infinitely more by the approximation of the centres of action than it was diminished by the extreme smallness of the masses, consequently the attraction is infinite." *Dict. de Physique*, vol. i. p. 100.

It has been suggested by La Place, that the distances between the molecules of bodies may be incomparably greater than the diameters of the molecules themselves, so that the density of each molecule is much greater than the density of the body in which it exists, or the density which it would have, if all the matter of the molecule were uniformly distributed within the body. The attraction of a particle touching a sphere composed of these dense molecules would thus be very great, compared with the attraction which it would experience at a finite distance, even when the law of action was the same as that of gravity; so that if matter is thus constituted, the attraction of affinity may, in all probability, be only a case of universal gravitation. See COHESION, CAPILLARY Attraction, ELECTRICITY, MAGNETISM, and OPTICS. (o)

ATTRACTION OF MOUNTAINS. If every portion of matter is attracted by every other portion of matter, with a force directly proportional to the number of gravitating particles, and inversely as the square of the distance, it might naturally be expected, that the attractive force of a large and solid mountain might be determined by direct experiments. Though the clouds and vapours which crown the summits of lofty mountains, or hover along their sides, evidently indicate the exertion of an attractive force, yet astronomers have sought for a more unequivocal proof of its existence, by measuring the deflection which it produced in attracting a plumb-line from its perpendicular position.

The earliest hint of this method was suggested by Sir Isaac Newton; and it was first put in execution by the French academicians, who were sent to measure a degree of the meridian in Peru. The celebrated Bouguer

selected the mountain Chimboraco as the most proper for this purpose; and from a rough calculation he concluded, that its attraction would be equal to the 1000th part of that of the whole earth, and might produce a deviation in the plumb-line of nearly 43 seconds. In order to determine this experimentally, Bouguer and Condamine observed the altitudes of several stars from two stations, one on the north, and the other on the south side of the mountain. The difference between the altitudes obtained on each side, diminished by the difference of latitude between the two stations will be double of the angle of deviation produced by the action of the mountain. Thus, in Plate XLIX. Fig. 1. if the plumbets are attracted into the positions AB, CD, deviating from the vertical lines AP, CO, by the angles PAB, OCD, the difference of latitude between the stations O, P, which is measured by the celestial arch MN, will, in consequence of the deviation of the plumb-line, be measured by the arch *mn*. But the arch MN is known from the distance between the stations O, P; therefore, by subtracting the arch MN from the arch *mn*, found by taking the altitudes of a star, we obtain the sum of the arches *Mn*, *Nn*, which measure the two angles of deviation PAB, OCD, produced by the attraction of the mountain. In the case of Chimboraco, the angle of deviation was 8 seconds.

This interesting experiment was repeated in this country by the learned Dr Maskelyne, with the view not merely of ascertaining in general the attraction of mountains, but for the purpose of determining from the result the mean density of the earth. The hill of Shehallien, in the county of Perth in Scotland, was reckoned the most convenient for this purpose, and preparations were made for executing this laborious undertaking in the summer of 1774. An observatory was erected about half way up the north side of the hill, and was afterwards removed to a similar position on the south side. No fewer than 337 observations were made with an excellent zenith sector of Sisson's upon 43 fixed stars; and it appeared from these observations, that the difference of latitude between the two stations was $54''.6$. By the trigonometrical survey it was found, that the distance between the stations was 4364 4 feet, which in the latitude of $56^{\circ} 40'$ answers to a difference of latitude equal to $42''.94$. The difference between these results, viz. $11''.6$, is obviously the sum of the two deflections of the plumb-line, and therefore $5''.8$ is the measure of the attraction of Shehallien. A complete survey of the mountain was next made, in order to determine its form and dimensions, for the purpose of calculating the attraction which it exerted upon the plumb-line of the sector. In order to accomplish this, the hill was supposed to be divided into a number of vertical pillars, and the action of each pillar upon the plumb-line was computed from its altitude and its distance from the observatory. From these computations, which were made with great labour by the learned Dr Charles Hutton, it appeared, that the whole attraction of the earth was to the sum of the two contrary attractions of the earth, as 9933 to 1, the density of the hill being supposed to be equal to the mean density of the earth. But the attraction of the earth is to the sum of the attractions of the hill nearly as radius is to the tangent of $11''.6$; that is, as 17804 to 1, consequently the mean density of the earth is to the mean density of the hill as 17804 to 9933, or nearly as 9 to 5. Dr Hutton supposes the mean density of the hill to be nearly that of common free stone,

or 2.5, consequently the density of the mountain will be had from the following analogy:
 $5 : 9 :: 2.5 : 4.5$ the earth's density, that of water being 1.

It is obvious, that the accuracy of this result depends on the correctness of the number 2.5, which is assumed as the average density of the hill. With the view of ascertaining the real density of Shehallien, a complete mineralogical survey of it has been recently made by Professor Playfair. He found that it consisted of granular quartz, whose average density was 2.64, and of mica slate, whose average density was 2.81; and that the density of a homogeneous mountain, that would have produced the same effect upon the plumb-line, was 2.716. Mr Playfair has, with great labour, computed the correction that must be made on the attraction of the mountain, in consequence of the variation in the specific gravity of its parts; and it would appear from these calculations, that the earth's density is about 4.867, a result which approaches nearer than the former to the result of Mr Cavendish's experiments on the attraction of leaden balls. A detailed account of Mr Playfair's survey and calculations will, we trust, be soon given to the public. To the kindness of that celebrated philosopher, the editor has been indebted for the preceding interesting facts.

The experiments made by Mr Cavendish on the attraction of leaden balls, in order to determine the density of the earth, are so intimately connected with the attraction of mountains, that we cannot omit the present opportunity of presenting our readers with an account of the apparatus which he employed, and of the results to which he was conducted.

This ingenious and simple machine was invented for the purpose of measuring the earth's density, by the Rev. John Michell, a young and accomplished philosopher, who was carried off in early life from the scientific labours which he had so successfully begun. It afterwards came into the hands of Mr Cavendish, who made a few improvements on its construction, and conducted the experiment to a successful issue.

A longitudinal vertical section of the instrument is represented in Plate XLIX. Fig. 2. where GGHH is the building in which it was placed, and ABCDD CBAEFFE its case; x and x are the two balls which are suspended by the wires hx from the arm $ghmh$, which is itself suspended by the slender wire gl . This arm consists of a slender deal rod hmh , strengthened by a silver wire hgh , which renders it sufficiently strong to support the balls.

The case, which rests on posts β , β , firmly fixed into the ground, is supported and set horizontal by four screws, two of which are seen at S, S. W and W are the leaden weights or balls, which are suspended from the centre-pin P*h* by the copper rods R*r*, P*r*R, and the wooden box *rr*. This centre pin passes through a hole in the beam HH, perpendicularly over the centre of the instrument, and turns round in it, being prevented from falling by the plate β . MM is a pulley fastened to this pin, and M*m* a cord coiled round the pulley, and passing through the end wall GG. By means of this cord the observer may turn round the pulley MM, and move the weights from one situation to the other.

It is obvious that the weights W, W conspire, by their action on the balls x , x , to turn the arm hgh in the same direction. Slips of ivory, divided into 20ths of an inch, are placed within the case at A, A, as near

to the end of the arm as possible, for the purpose of determining its position. A small vernier scale, made of ivory, is fixed at the end of each arm, by means of which their motion may be estimated to less than the 100th of an inch. These divisions are viewed by means of the short telescopes T and T, through slits cut in the end of the case, and stopped with glass. They are illuminated by the lamps L and L with convex glasses, so placed as to throw their light on the divisions, the room being in every other respect dark. By means of the wooden rod F*K*, with an endless screw at its extremity, the observer is enabled to turn round the support δ , to which the wire gl is fastened, and then to move the wire till the arm settles in the middle of the case.

Let us now suppose that the arm hgh is at rest in a known position; then when the weights are moved, the arm will instantly be drawn aside by their attraction, but it will be made to vibrate, and its vibration will continue a great while. By measuring the length of these vibrations, and the time of their continuance, Cavendish found that the force which must be applied to each ball x , in order to draw the arm one division out of its natural position, is $\frac{1}{818N^2}$, N being the time of a vibration

in seconds; and that the attraction of the weight on the ball is to the attraction of the earth upon it as .9779 to 1, or as 1 to 8739000 D, D being the density of the earth, and each of the weights weighing 2439000 grains, or being equal to 10.64 spherical feet of water. The attraction of the weight upon the ball will therefore be

$\frac{1}{8739000D}$ of the weight of that ball, and consequently the attraction will be able to draw the arm out of its natural position by $\frac{818N^2}{8739000D}$, or $\frac{N^2}{10683D}$ divisions;

and therefore, if, on moving the weights from the midway to a new position, the arm is found to move B divisions, or if it moves 2B divisions on moving the weights from one near position to the other, it follows that the density of the earth, or D, is $\frac{N^2}{10683B}$.

After correcting this result as obtained from each experiment, Mr Cavendish obtained the following Table of densities:

5.5	5.57	5.42
5.61	5.53	5.47
5.88	5.62	5.63
5.07	5.29	5.34
5.26	5.44	5.46
5.55	5.34	5.3
5.36	5.79	5.75
5.29	5.1	5.68
5.58	5.27	5.85
5.65	5.39	

From these results, it appears, that the mean density of the earth is nearly 5.48, a result considerably greater than that which was deduced from the attraction of Shehallien.

Another method of ascertaining the attraction of matter has been suggested by the learned Dr Robison. He supposes that a sensible effect might be produced on a long plummet, or a nice spirit level, by the immense quantity of water which is brought to Annapolis Royal in Nova Scotia twice every day by the tides, which rise above an hundred feet. "If a leaden pipe," he observes,

“a few hundred feet long, were laid on the level beach at right angles with the coast, and a glass pipe set upright at each end, and the whole filled with water; the water will rise at the outer end, and sink at the end next the land as the tide rises.” See Bouguer’s *Traité de la Figure de Terre. Phil. Trans.* 1775, vol. lxxv. part ii. p. 495, 500. Id. 1778, vol. lxxviii. p. 689. Id. 1798, p. 469. Pringle *On the Attraction of Mountains*, 9to, Lond. 1775; and Robison’s *Elements of Mechanical Philosophy*, vol. i. p. 359. (c)

ATTRACTION OF SOLIDS. As this subject is so intimately connected with the important experiments on the attraction of mountains and leaden balls, and with many other branches of physics, and as it cannot be introduced with propriety under any other head, we shall present the reader with some of the most important and useful propositions, referring to other works for the complete discussion of the subject.

In the chapter of *Physical Astronomy*, entitled, *On the Gravitation of a Sphere*, we have already entered upon the subject as connected with astronomy; we shall therefore resume the discussion where it was left in that article, following implicitly the steps of Newton, in so far as he has prosecuted the subject in the first book of his *Principia*. We shall then consider the subject of the solids of greatest attraction, which has been recently treated with such ability by Professor Playfair, availing ourselves of the kind permission of that distinguished philosopher, to give an abridged view of his valuable paper.

We have already seen, in the article already mentioned, that when the law of the force exerted by the particles is inversely as the square of the distance, the centripetal forces of the spheres themselves, on receding from the centre, decrease or increase according to the same law. It will appear from the two following propositions, that when the law of the force varies in the simple inverse ratio of the distance, the centripetal forces of the spheres in receding from the centre will vary according to the same law as the forces of the particles.

If centripetal forces tend to the several points of spheres, proportional to the distances of those points from the attracted bodies; the compounded force, with which two spheres will attract each other mutually, is as the distance between the centres of the spheres.

Case 1. Let AEBF be a sphere; S its centre; P a particle attracted; PASB the axis of the sphere passing through the centre of the particle; EF, *ef*, two planes, by which the sphere is cut, perpendicular to this axis, and equally distant on each side from the centre of the sphere; G, *g*, the intersections of the planes and the axis: and H any point in the plane EF. The centripetal force of the point H upon the particle P, exerted in the direction of the line PH, is as the distance PH; and according to the direction of the line PG, or towards the centre S, is as the length PG. Therefore, the force of all the points in the plane EF, that is, the force of the whole plane, by which the particle P is attracted towards the centre S, is as the distance PG multiplied by the number of those points; that is, as the solid which is contained under that plane EF and the distance PG. And, in like manner, the force of the plane *ef*, with which the particle P is attracted towards the centre S, is as that plane multiplied into its distance P*g*, or as the equal plane EF multiplied into that distance P*g*: and the sum of the forces of both planes as the plane

EF multiplied into the sum of the distance PG + P*g*, that is, as that plane multiplied into double the distance PS of the centre and the particle; that is, as double the plane EF multiplied into the distance PS; or as the sum of the equal planes EF + *ef* multiplied into the same distance. And, by a like reasoning, the forces of all the planes in the whole sphere, equally distant on each side from the centre of the sphere, are as the sum of the planes multiplied into the distance PS; that is, as the whole sphere and as the distance PS jointly.

Case 2. Let the particle P now attract the sphere AEBF. And, by the same reasoning, it will be proved, that the force, with which that sphere is attracted, is as the distance PS.

Case 3. Let another sphere be now composed of innumerable particles P; and, since the force, with which each particle is attracted, is as the distance of the particle from the centre of the first sphere, and as the same sphere jointly; and therefore is the same, as if the whole proceeded from one particle in the centre of the sphere; the whole force, with which all the particles in the second sphere are attracted, that is, with which that whole sphere is attracted, will be the same, as if that sphere was attracted by a force proceeding from one particle in the centre of the first sphere; and therefore is proportional to the distance between the centres of the spheres.

Case 4. Let the spheres attract each other mutually, and the force being doubled will preserve the former proportion.

Case 5. Let the particle *p* be now placed within the sphere AEBF; and, since the force of the plane *ef* upon the particle is as the solid contained under that plane and the distance *fg*; and the contrary force of the plane EF as the solid contained under that plane and the distance *fG*; the force compounded of both will be as the difference of the solids; that is, as the sum of the equal planes multiplied into half the difference of the distances; that is, as that sum multiplied into *fS*, the distance of the particle from the centre of the sphere. And, by a like reasoning, the attraction of all the planes EF, *ef* in the whole sphere, that is, the attraction of the whole sphere is jointly as the sum of all the planes, or as the whole sphere, and as *fS* the distance of the particle from the centre of the sphere.

Case 6. And, if a new sphere be composed of innumerable particles *p*, placed within the former sphere AEBF; it may be proved as before, that either the single attraction of one towards the other, or the mutual attraction of both towards each other, will be as the distance of the centres *fS*.

If spheres are dissimilar and inequable in proceeding directly from the centre to the circumference; but are every where similar at every given distance in a circumference around; and the attractive force of every point is as the distance of the attracted body: the whole force, with which two spheres of this kind attract each other is proportional to the distance between the centres of the spheres.

This is demonstrated from the preceding proposition, in the same manner as the Proposition in Chap. V. p. 691. col. 1. of *Physical Astronomy* was demonstrated.

Cor. Those things which are demonstrated of the motion of bodies round the centres of conic sections, take place, when all the attractions are made by the force of spherical bodies of the quality already described, and the attracted bodies are spheres of the same kind.

If any circle AEB is described with the centre S; and two circles EF, *ef* are described with the centre P, cutting the former in E, *e*, and the line PS in F*f*; and ED, *ed* be let fall perpendicular to PS; then, if the distance of the arcs EF, *ef* is supposed to be continually diminished, the limit of the ratios of the variable line D*d* to the variable line F*f* is the same as the ratio of the line PE to the line PS.

For, if the line Pe cuts the arc EF in *g*; and the right line E*e*, which approaches nearer than by any assignable difference to the arc E*e*, be produced, and meet the right line PS in T; and SG be let fall from S, perpendicular to PE: because of the similar triangles DTE, dTe, DES, D*d* will be to E*e*, as DT to TE, or DE to ES: and, because of the similar triangles E*e*g, ESG, E*e* will be to *eg* or F*f*, as ES to SG; and, *ex æquo*, D*d* to F*f*, as DE to SG; that is, because of the similar triangles PDE, PGS, as PE to PS.

If EF*e*, considered as a surface, by reason of its breadth being indefinitely diminished, describes a spherical concavo-convex solid by its revolution round the axis PS, to the several equal particles of which there tend equal centripetal forces; the force, with which that solid attracts a particle placed in P, is in a ratio compounded of the ratio of the solid DE² × F*f*, and the ratio of the force, with which a given particle in the place F*f* would attract the same particle in P.

For, if we first consider the force of the spherical surface FE, which is generated by the revolution of the arc FE, and is any where cut in *r* by the line *de*; the annular part of the surface, generated by the revolution of the arc *rE*, will be as the small line D*d*, the radius of the sphere PE remaining the same; as Archimedes has demonstrated in his book concerning the sphere and cylinder. And the force of this, exerted in the direction of the lines PE or Pr, placed around in a conical surface, is as this annular surface itself; that is, as the line D*d*; or, which is the same, as the rectangle under the given radius PE of the sphere, and that line D*d*: but that force, acting in the direction of the line PS tending to the centre S, is less, in the ratio of PD to PE, and therefore as PD × D*d*. Let the line DF be now supposed to be divided into innumerable equal particles, each of which may be called D*d*; and the surface FE will be divided into as many equal annuli, whose forces will be as the sum of all the rectangles PD × D*d*; that is, as $\frac{1}{2}PF^2 - \frac{1}{2}PD^2$, and therefore as DE². Let the surface FE be now multiplied into the altitude F*f*; and the force of the solid EF*e*, exerted upon the particle P, will be as DE² × F*f*; supposing that the force is given, which any given particle F*f* exerts upon the particle P, at the distance PF. But, if that force is not given, the force of the solid EF*e* will be as the solid DE² × F*f*; and that force not given, jointly.

If equal centripetal forces tend to the several equal parts of any sphere ABE, described about the centre S; and, from the several points D, perpendiculars DE are arc erected to the axis of the sphere AB, in which any particle P is placed meeting the sphere in E; and in those perpendiculars the lengths DN are taken, which arc as the quantity $\frac{DE^2 \times PS}{PE}$, and the force which a particle of the sphere, placed in the axis at the distance PE, exerts upon the particle P, jointly; I say, that the whole force with which the particle P is attracted towards the sphere, is as the area ANB, contained

between AB the axis of the sphere, and the curve line ANB, which the point N continually touches.

For, supposing the construction in the last lemma and theorem to remain, conceive the axis of the sphere AB to be divided into innumerable equal parts D*d*, and the whole sphere to be divided into as many spherical concavo-convex laminæ EF*e*, and let the perpendicular *de* be erected. By the last theorem, the force, with which the lamina EF*e* attracts the particle P is as DE² × F*f*, and the force of one particle exerted at the distance PE or PF, jointly. But, by the last lemma, D*d* is to F*f* as PE to PS; and therefore F*f* is equal to $\frac{PS \times Dd}{PE}$; and

DE² × F*f* is equal to $Dd \times \frac{DE^2 \times PS}{PE}$; and therefore

the force of the lamina EF*e* is as $Dd \times \frac{DE^2 \times PS}{PE}$; and

the force of a particle exerted at the distance PF, jointly; that is from the supposition, as DN × D*d*, or as the indefinitely small area DN*d*. Therefore the forces of all the laminæ, exerted upon the particle P, are as all the areas DN*d*; that is, the whole force of the sphere is as the whole area ANB.

Corol. 1. Hence, if the centripetal force tending to the several particles remains always the same at all distances, and D*n* be made as $\frac{DE^2 \times PS}{PE}$, the whole force, with which the particle P is attracted by the sphere, is as the area ANB.

Corol. 2. If the centripetal force of the particles is reciprocally as the distance of the particle attracted by it, and DN is made as $\frac{DE^2 \times PS}{PE^2}$; the force, with which the particle P is attracted by the whole sphere, will be as the area ANB.

Cor. 3. If the centripetal force of the particles is reciprocally as the cube of the distance of the particle attracted by it, and DN is made as $\frac{DE^2 \times PS}{PE^3}$; the force, with which the particle P is attracted by the whole sphere, will be as the area ANB.

Cor. 4. And universally, if the centripetal force, tending to the several particles of a sphere, is supposed to be reciprocally as the quantity V, and DN is made as $\frac{DE^2 \times PS}{PE \times V}$, the force, with which a particle is attracted by the whole sphere, will be as the area ANB.

Supposing what has been already established, it is required to measure the area ANB.

From the point P let the right line PH be drawn, touching the sphere in H; and having let fall HI perpendicular to the axis PAB, let PI be bisected in L; and PE² will be equal to PS² + SE² + 2PSD. But, because the triangles SPH, SHI are similar, SE² or SH² is equal to the rectangle PSI. Therefore PE² is equal to the rectangle contained under PS and PS + SI + 2SD; that is, under PS and 2LS + 2SD; that is, under PS and 2LD. Moreover, DE² is equal to SE² - SD², or SE² - LS² + 2SLD - LD²; that is, 2SLD - LD² - ALB. For LS² - SE², or LS² - SA², is equal to the rectangle ALB. Let therefore 2SLD - LD² - ALB be substituted for DE²; and the quantity $\frac{DE^2 \times PS}{PE \times V}$, which, according to the fourth *corollary* of the preceding proposition, is as the length

of the ordinate DN, will resolve itself into three parts, $\frac{2SLD \times PS}{PE \times V} - \frac{LD^2 \times PS}{PE \times V} - \frac{ALB \times PS}{PE \times V}$: where, if instead of V the inverse ratio of the centripetal force is substituted; and, instead of PE, the mean proportional between PS and 2LD; those three parts will become ordinates of as many curve lines, whose areas are found by the common methods.

Example 1. If the centripetal force, tending to the several particles of a sphere, is reciprocally as the distance, for V substitute the distance PE; then $2PS \times LD$ for PE^2 ; and DN will become as $SL - \frac{1}{2}LD - \frac{ALB}{2LD}$. Suppose DN equal to the double of this, $2SL - LD - \frac{ALB}{LD}$; and 2SL, the given part of the ordinate, drawn into the length AB, will describe the rectangular area $2SL \times AB$; and the indefinite part LD, drawn perpendicularly into the same length, by a continual motion, made according to such a law, that, in its motion, it may either by increasing or decreasing be always equal to the length LD, will describe the area $\frac{LB^2 - LA^2}{2}$; that is, the area $SL \times AB$; which, taken from the former area $2SL \times AB$, leaves the area $SL \times AB$. But the third part $\frac{ALB}{LD}$, drawn after the same manner, by a continual motion, perpendicularly into the same length, will describe an hyperbolic area; which, taken from the area $SL \times AB$, will leave ANB the area sought. Whence this construction of the problem arises. At the points L, A, B, erect the perpendiculars Ll, Aa, Bb ; of which Aa may be equal to LB, and Bb to LA. With the asymptotes Ll, LB let the hyperbola ab be described through the points a, b . And the chord ba will inclose the area $ab a$, equal to the area ANB sought.

Example 2. If the centripetal force, tending to the several particles of a sphere, is reciprocally as the cube of the distance; or, which is the same thing, as that cube applied to any given plane; substitute $\frac{PE^3}{2AS^2}$ for V, then $2PS \times LD$ for PE^2 ; and DN will become as $\frac{SL \times AS^2}{PS \times LD} - \frac{AS^2}{2PS} - \frac{ALB \times AS^2}{2PS \times LD^2}$; that is, because PS, AS, SI are continually proportional, as $\frac{LSI}{LD} - \frac{1}{2}SI - \frac{ALB \times SI}{2LD^2}$. If the three parts of this quantity are drawn into the length AB, the first $\frac{LSI}{LD^2}$ will generate an hyperbolic area; the second $\frac{1}{2}SI$ the area $\frac{1}{2}AB \times SI$; the third $\frac{ALB \times SI}{2LD^2}$, the area $\frac{ALB \times SI}{2LA} - \frac{ALB \times SI}{2LB}$, that is, $\frac{1}{2}AB \times SI$. From the first let the sum of the second and third be subducted, and there will remain ANB the area sought. Whence this construction of the problem arises. At the points L, A, S, B, erect the perpendiculars Ll, Aa, Ss, Bb , of which let Ss be equal to SI; and through the point s with the asymptotes Ll, LB , let the hyperbola $as b$ be described, meeting the perpendiculars Aa, Bb in a and b ; and the rectangle $2ASI$, subducted from the hyperbolic area $A a s b B$, will leave the area ANB sought.

Example 3. If the centripetal force, tending to the several particles of a sphere, decreases in the quadru-

plicate ratio of the distance from the particles; substitute $\frac{PE^4}{2AS^3}$ for V, then $\sqrt{2PS \times LD}$ for PE, and DN will

become as $\frac{SI^2 \times SL}{\sqrt{2SI}} \times \frac{1}{\sqrt{LD^3}} - \frac{SI^2}{2\sqrt{2SI}} \times \frac{1}{\sqrt{LD}} - \frac{SI^2 \times ALB}{2\sqrt{2SI}} \times \frac{1}{\sqrt{LD^3}}$. Whose three parts, drawn into the length AB, produce as many areas, namely, $\frac{2SI^2 \times SL}{\sqrt{2SI}}$ into $\frac{1}{\sqrt{LA}} - \frac{1}{\sqrt{LB}}$; $\frac{SI^2}{\sqrt{2SI}}$ into $\frac{1}{\sqrt{LB}} - \frac{1}{\sqrt{LA}}$; and $\frac{SI^2 \times ALB}{3\sqrt{2SI}}$ into $\frac{1}{\sqrt{LA^3}} - \frac{1}{\sqrt{LB^3}}$. And these, after a due reduction, become $\frac{2SI^2 \times SL}{LI}$, SI^2 and $SI^2 + \frac{2SI^3}{3LI}$. But these, by taking away the latter terms from

the former, become $\frac{4SI^3}{3LI}$. Therefore the whole force, with which the particle P is attracted to the centre of the sphere, is as $\frac{SI^3}{PI}$; that is, reciprocally as $PS^3 \times PI$.

The attraction of a particle placed within a sphere may be determined by the same method; but more expeditiously by the following proposition.

If SI, SA, SP are taken continually proportional, in a sphere described about the centre S, with the interval SA; the attraction of a particle within the sphere, in any place I, is to its attraction without the sphere in the place P, in a ratio compounded of the subduplicate ratio of IS, PS, the distances from the centre, and the subduplicate ratio of the centripetal forces, tending to the centre in those places P and I.

As, if the centripetal forces of the particles of a sphere are reciprocally as the distances of a particle attracted by them, the force, with which a particle placed in I is attracted by the whole sphere, will be to the force, with which it is attracted in P, in a ratio compounded of the subduplicate ratio of the distance SI to the distance SP, and the subduplicate ratio of the centripetal force in the place I, arising from any particle in the centre, to the centripetal force in the place P, arising from the same particle in the centre; that is, in the subduplicate ratio of the distances SI, SP to each other reciprocally. These two subduplicate ratios compound the ratio of equality; and therefore the attractions in I and P, produced by the whole sphere, are equal. By a like calculation, if the forces of the particles of a sphere are reciprocally in the duplicate ratio of the distances, it will be collected, that the attraction in I is to the attraction in P, as the distance SP, to SA the semidiameter of the sphere. If those forces are reciprocally in the triplicate ratio of the distances, the attractions in I and P will be to each other as SP^2 to SA^2 ; if in a quadruplicate ratio, as SP^3 to SA^3 . Therefore, since the attraction in P, in this last case, was found to be reciprocally as $PS^3 \times PI$, the attraction in I will be reciprocally as $SA^3 \times PI$; that is, because SA^3 is given, reciprocally as PI. And the progression is the same indefinitely. The theorem is therefore demonstrated.

Retaining the construction above, and a particle being in any place P, the ordinate DN was found as $\frac{DE^2 \times PS}{PE \times V}$. Therefore, if EI is drawn, that ordinate

for any other place I of the particle will become as $\frac{DE^2 \times IS}{IE \times V}$ (changing PS, and PE, for IS, and IE.)

Suppose the centripetal forces, flowing from any point E of the sphere, to be to each other at the distances IE, PE, as PE^n to IE^n (where the number n denotes the index of the powers of PE and IE); and those ordinates will become as $\frac{DE^2 \times PS}{PE \times PE^n}$, and $\frac{DE^2 \times IS}{IE \times IE^n}$; whose ratio to each other is as $PS \times IE \times IE^n$ to $IS \times PE \times PE^n$. Since the triangles SPE, SEI are similar, on account of the lines SI, SE, SP being continually proportional; and from thence it follows, that IE is to PE, as IS to SE or SA; for the ratio of IE to PE substitute the ratio of IS to SA; and the ratio of the ordinates will become that of $PS \times IE^n$ to $SA \times PE^n$. But the ratio of PS to SA is the subduplicate ratio of the distances PS, SI; and the ratio of IE^n to PE^n (because IE is to PE, as IS to SA) is the subduplicate ratio of the forces at the distances PS, IS. Therefore the ordinates, and consequently the areas which the ordinates describe, and the attractions proportional to them, are in a ratio compounded of these subduplicate ratios.

To find the force, with which a particle, placed in the centre of a sphere, is attracted to any segment of that sphere.

Let P be a particle in the centre of a sphere, and RBSD a segment thereof, contained between the plane RDS, and the spherical surface RBS. Let BD be cut in F by a spherical surface EFG, described from the centre P; and let the segment be divided into the parts BREFGS, FEDG. But, let that surface be not purely mathematical, but physical, having a very inconsiderable thickness. Let that thickness be called O, and the surface, according to the demonstration of Archimedes, will be as $PF \times DF \times O$. Let us suppose moreover, that the attractive forces of the particles of the sphere are reciprocally as that power of the distances whose index is n ; and the force, with which the surface EFG attracts the body P, will be as $\frac{DE^2 \times O}{PF^n}$; that is, as $\frac{2DF \times O}{PF^{n-1}} - \frac{DF^2 \times O}{PF^n}$.

Let the perpendicular FN, drawn into O, be proportional to this quantity; and the curvilinear area BDI, which the ordinate FN, drawn through the length DB by a continual motion, describes, will be as the whole force, with which the whole segment RBSD attracts the body P.

To find the force, with which a particle, placed without the centre of a sphere, in the axis of any segment, is attracted by that segment.

Let the body P, placed in the axis ADB of the segment EBK, be attracted by that segment. With the centre P, at the interval PE, let the spherical surface EFK be described; with which let the segment be divided into two parts EBKFE, and EFKDE. Let the force of the former part be sought by Prop. V. and the force of the latter part by Prop. VII. and the sum of the forces will be the force of the whole segment EBKDE.

If one body is attracted by another, and the attraction is very much stronger when it is contiguous to the attracting body, than when they are separated from each other by any interval, how small soever, the forces of the particles of the attracting body, in the recess of the body attracted, decrease in a greater than the duplicate ratio of the distances from the particles.

For, if the forces decrease in a duplicate ratio of the

distances from the particles, the attraction towards a spherical body, being reciprocally as the square of the distance of the attracted body from the centre of the sphere, will not be sensibly increased by the contact; and it will be still less increased by the contact, if the attraction in the recess of the body attracted decreases in a less ratio. The proposition therefore is evident concerning attractive spheres. And the case of concave spherical orbs attracting external bodies is the same. And it is much more evident in orbs which attract bodies placed within them; because the attractions, diffused every where through the cavities of the orbs, are destroyed by contrary attractions, (See Chap. V. *Physical Astronomy*;) and therefore have no effect even in contact. But, if from these spheres and spherical orbs any parts remote from the place of contact are taken away, and new parts are added any where, the figures of these attractive bodies may be changed at pleasure; and yet the parts added or taken away, being remote from the place of contact, will not remarkably increase the excess of attraction which arises from the contact. The proposition therefore is evident in bodies of all figures.

If the forces of the particles, of which an attractive body is composed, decrease, in the recess of the attracted body, in a triplicate or more than a triplicate ratio of the distances of the particles, the attraction will be very much stronger in contact, than when the attracting and attracted bodies are separated from each other by any interval, how small soever.

For it appears by the solution of Prop. V. exhibited in the second and third examples, that the attraction is indefinitely increased, when an attracted particle approaches to an attracting sphere of this kind. The same thing is also easily collected, by comparing those examples, and Prop. VI. together, concerning the attractions of bodies towards concavo-convex orbs, whether the attracted bodies are placed without the orbs, or within their cavities. But the proposition will also be universally evident concerning all bodies, by adding or taking away from these spheres and orbs any attractive matter, any where without the place of contact, so that the attractive bodies may assume any assigned figure.

If two bodies, similar to each other, and consisting of matter equally attractive, attract separately particles proportional to, and similarly situated with respect of themselves, the accelerative attractions of the particles towards the whole bodies will be, as the accelerative attractions of those particles towards particles of the bodies proportional to the whole, and similarly situated in them.

For, if the bodies are divided into particles, which are proportional to the whole bodies, and similarly situated in them, it will be, as the attraction towards any particle of one body is to the attraction towards the corresponding particle of the other body, so are the attractions towards the several particles of the first body, to the attractions towards the several corresponding particles of the other body; and, by composition, so is the attraction towards the first whole body, to the attraction towards the second whole body.

Cor. 1. Therefore, if the attractive forces of particles, by increasing the distances of the attracted particles, decrease in the ratio of any power of the distances, the accelerative attractions towards the whole bodies will be, as the bodies directly, and those powers of the dis-

tances inversely. As, if the forces of particles decrease in a duplicate ratio of the distances from the particles attracted, and the bodies are as A^3 and B^3 ; and therefore both the cubic sides of the bodies, and the distances of the attracted particles from the bodies, are as A and B ; the accelerative attractions towards the bodies will be as $\frac{A^3}{A^2}$ and $\frac{B^3}{B^2}$; that is, as A and B the cubic sides of the bodies. If the forces of particles decrease in the triplicate ratio of the distances from the attracted particles, the accelerative attractions towards the whole bodies will be as $\frac{A^3}{A^3}$ and $\frac{B^3}{B^3}$; that is, equal. If the forces decrease in a quadruplicate ratio, the attractions towards the bodies will be as $\frac{A^3}{A^4}$ and $\frac{B^3}{B^4}$; that is, reciprocally as the cubic sides A and B . And so on in other cases.

Cor. 2. Hence, on the contrary, the ratio of the decrease of the forces of attractive particles, in the recess of the attracted particle, may be collected from the forces, with which similar bodies attract particles similarly situated; if only that decrease is directly or inversely in any ratio of the distances.

If the attractive forces of equal particles of any body are as the distances of the places from the particles; the forces of the whole body will tend to its centre of gravity; and will be the same with the force of a globe, consisting of similar and equal matter, and having its centre in the centre of gravity.

Let the particles A, B , of the body $RSTV$ attract any particle Z with forces, which, if the particles are equal to each other, are as the distances AZ, BZ ; but, if the particles are supposed unequal, are as those particles, and their distances AZ, BZ , jointly; or, as those particles drawn into their distances AZ, BZ , respectively. And let these forces be expressed by those contents, $A \times AZ$ and $B \times BZ$. Let AB be joined, and let it be cut in G , so that AG may be to BG , as the particle B to the particle A ; and G will be the common centre of gravity of the particles A and B . The force $A \times AZ$ is resolved into the forces $A \times GZ$ and $A \times AG$; and the force $B \times BZ$ into the forces $B \times GZ$ and $B \times BG$. But the forces $A \times AG$ and $B \times BG$, because A is to B as BG to AG , are equal; and therefore, when they are directed towards contrary parts, destroy each other. The forces $A \times GZ$ and $B \times GZ$ remain. These tend from Z towards the centre G , and compose the force $\frac{A+B}{2} \times GZ$; that is, the same force, as if the attractive particles A and B were placed in their common centre of gravity G , composing there a globe.

By the same reasoning, if a third particle C is added, and the force of this is compounded with the force $\frac{A+B}{2} \times GZ$, tending to the centre G ; the force thence arising will tend to the common centre of gravity of that globe in G , and of the particle C ; that is, to the common centre of gravity of the three particles A, B, C ; and will be the same as if that globe and the particle C were placed in that common centre, composing there a greater globe. And thus we may go on continually. Therefore, the whole force of all the particles of any body $RSTV$ is the same as if that body, preserving its centre of gravity, was to assume the figure of a globe.

Cor. Hence, the motion of the attracted body Z will be the same, as if the attracting body $RSTV$ was spherical: and therefore, if that attracting body is either at rest, or proceeds uniformly in a right line, the body at-

tracted will move in an ellipsis, having its centre in the centre of gravity of the attracting body.

If there are several bodies consisting of equal particles, whose forces are as the distances of the places from each; the force, compounded of the forces of all, by which any particle is attracted, will tend to the common centre of gravity of the attracting bodies; and will be the same as if those attracting bodies, preserving their common centre of gravity, should unite there, and be formed into a globe.

This is demonstrated in the same manner as the foregoing proposition.

Cor. Therefore the motion of the attracted body will be the same, as if the attracting bodies, preserving their common centre of gravity, should unite there, and be formed into a globe. And therefore, if the common centre of gravity of the attracting bodies is either at rest, or proceeds uniformly in a right line, the body attracted will move in an ellipsis, having its centre in that common centre of gravity of the attracting bodies.

If equal centripetal forces tend to the several points of any circle, increasing or decreasing in any ratio of the distances; it is required to find the force with which a particle is attracted, placed any where in a right line, which stands perpendicularly to the plane of the circle at its centre.

Suppose a circle to be described about the centre A , with any interval AD , in a plane, to which the right line AP is perpendicular; and let it be required to find the force, with which any particle P is attracted towards the same. Let the right line PE be drawn to the attracted particle P from any point E of the circle. In the right line PA let PF be taken equal to PE , and let the perpendicular FK be erected, which may be as the force with which the point E attracts the particle P . And let IKL be the curve line, which the point K continually touches. Let that curve meet the plane of the circle in L . In PA let PH be taken equal to PD ; and let the perpendicular HI be erected, meeting the curve in I ; and the attraction of the particle P towards the circle will be as the area $AHIL$, multiplied into the altitude AP .

For, let a very small line Ee be taken in AE . Let Pe be joined; and let PC, Pf be taken in PE, PA , equal to Pe . And since the force, with which any point E of the annulus described about the centre A , with the interval AE in the aforesaid plane, attracts the body P towards itself, is supposed to be as FK ; and therefore the force, with which that point attracts the body P towards A , is

as $\frac{AP \times FK}{PE}$; and the force, with which the whole annulus attracts the body P towards A , is as the annulus

and $\frac{AP \times FK}{PE}$ jointly: but that annulus is as the rectangle under the radius AE and the breadth Ee ; and this rectangle (because PE and AE, Ee and CE are proportional) is equal to the rectangle $PE \times CE$ or $PE \times Ef$; the force, with which that annulus attracts the body P towards A , will be as $PE \times Ef$ and $\frac{AP \times FK}{PE}$ jointly; that

is, as the quantity contained under $Ef \times FK \times AP$; or as the area FKf multiplied into AP . And therefore the sum of the forces, with which all the annuli in the circle, which is described about the centre A with the interval AD , attract the body P towards A , is as the whole area $AHIKL$ multiplied into AP .

Cor. 1. Hence it appears, that, if the forces of the points decrease in the duplicate ratio of the distances, that is, if FK is as $\frac{1}{PF^2}$, and therefore the area AHIKL as $\frac{1}{PA} - \frac{1}{PH}$, the attraction of the particle P towards the circle will be as $1 - \frac{PA}{PH}$; that is, as $\frac{AH}{PH}$.

Cor. 2. And universally, if the forces of the points at the distances D, are reciprocally as any power D^n of the distances; that is, if FK is as $\frac{1}{D^n}$, and therefore the area AHIKL as $\frac{1}{PA^{n-1}} - \frac{1}{PH^{n-1}}$; the attraction of the particle P towards the circle will be as $\frac{1}{PA^{n-2}} - \frac{PA}{PH^{n-1}}$.

Cor. 3. And, if the diameter of the circle is increased indefinitely, and the number n is greater than unity, the attraction of the particle P towards the whole plane indefinitely increased will be reciprocally as PA^{n-2} ; because the other term $\frac{PA}{PH^{n-1}}$ will be less than any assignable quantity.

To find the attraction of a particle, placed in the axis of a round solid, to the several points of which there tend equal centripetal forces, decreasing in any ratio of the distances.

Let the particle P, placed in the axis AB, be attracted towards the solid DECG. Let this solid be cut by any circle RFS perpendicular to this axis; and in its semidiameter FS, in any plane PALKB passing through the axis, let the length FK be taken (by Prop. XIV.) proportional to the force, with which the particle P is attracted towards that circle. And let the point K touch the curve line LKI, meeting the planes of the exterior circles AL and BI in L and I; and the attraction of the particle P towards the solid will be as the area LABI.

Cor. 1. Hence it appears, that if the solid is a cylinder, described by the parallelogram ADEB revolved about the axis AB, and the centripetal forces tending to its several points are reciprocally as the squares of the distances from the points; the attraction of the particle P towards this cylinder will be as $AB - PE + PD$. For the ordinate FK (by Cor. 1. Prop. XIV.) will be as $1 - \frac{PF}{PR}$. The part 1, of this quantity, drawn into the length AB, describes the area $1 \times AB$. And the other part $\frac{PF}{PR}$, drawn into the length PB, describes the area 1 into $\overline{PE - AD}$, which may be easily shewn from the quadrature of the curve LKI: and, in like manner, the same part, drawn into the length PA, describes the area 1 into $\overline{PD - AD}$; and drawn into AB, the difference of PB, PA, describes 1 into $\overline{PE - PD}$, the difference of the areas. From the first content 1 into AB let the last content 1 into $\overline{PE - PD}$ be taken away, and the area LABI will remain equal to 1 into $AB - PE + PD$. Therefore the force, proportional to this area, is as $AB - PE + PD$.

Cor. 2. Hence also the force is known by which a spheroid AGBC attracts any body P, placed externally in its axis AB. Let NKRM be a conic section, whose ordinate ER, perpendicular to PE, may be always equal

to the length of the line PD, which is drawn to that point D, in which that ordinate cuts the spheroid. From the vertices A, B of the spheroid let AK, BM, be erected, perpendicular to its axis AB, respectively equal to AP, BP; and therefore meeting the conic section in K and M: and let KM be joined, cutting off from it the segment KMRK. Let S be the centre of the spheroid, and SC its greatest semidiameter; and the force, with which the spheroid attracts the body P, will be to the force, with which a sphere, described with the diameter AB, attracts the same body, as $\frac{AS \times CS^2 - PS \times KMRK}{PS^2 + CS^2 - AS^2}$ to $\frac{AS^3}{3PS^2}$. And, by the same principles of calculation the forces of the segments of the spheroid might be found.

Cor. 3. But, if the particle is placed within the spheroid in its axis, the attraction will be as its distance from the centre. Which may be more easily collected by the following reasoning, whether the particle is in the axis, or in any other given diameter. Let AGOD be the attracting spheroid, S its centre, and P the body attracted. Let the semidiameter SPA, and also two right lines DE, FG, meeting the spheroid in D and E, F and G, be drawn through that body: and let PCM, HLN, be the surfaces of two interior spheroids, similar and concentric to the exterior; of which let the former pass through the body P, and cut the right lines DE and FG in B and C; and let the latter cut the same right lines in H, I, and K, L. Let all the spheroids have one common axis, and the parts of the right lines intercepted on each side DP and BE, FP and CG, DH and IE, FK and LG, will be mutually equal; because the right lines DE, PB, and HI, are bisected in the same point; as also the right lines FG, PC, and KL. Conceive now DPF, EPG, to represent opposite cones, described with the indefinitely small verticle angles DPF, EPG, and the lines DH, EI, to be also indefinitely small: and the particles of the cones DIKF, GLIE, cut off by the surfaces of the spheroids, by reason of the equality of the lines DH, EI, will be to each other as the squares of their distances from the particle P, and therefore will attract that particle equally. And, by a like reasoning, if the spaces DPF, EGCB are divided into particles by the surfaces of innumerable similar spheroids, concentric to, and having a common axis with the former, all these will equally attract the body P on both sides towards contrary parts. Therefore the forces of the cone DPF, and of the conical segment EGCB, are equal, and by their contrary actions destroy each other mutually. And the case is the same of the forces of all the matter without the interior spheroid PCBM. Therefore the body P is attracted by the interior spheroid PCBM alone; and therefore (by Chap. IV. *Physical Astronomy*.) its attraction is to the force, with which the body A is attracted by the whole spheroid AGOD, as the distance PS to the distance AS.

An attracting body being given, it is required to find the ratio of the decrease of the centripetal forces, tending to its several points.

Of the body given, a sphere, or a cylinder, or some other regular figure is to be formed, whose law of attraction, agreeing to any ratio of decrease, may be found by Prop. IV. V. and XV. Then the force of attraction must be found by experiment of different distances; and the law of attraction towards the whole, thence discovered, will give the ratio of the decrease of the forces of the several parts.

If a solid, plane on one side, and indefinitely extended on all other sides, consists of equal particles equally attractive, whose forces, in receding from the solid, decrease in the ratio of any power of the distances greater than the square; and a particle, placed towards either part of the plane, is attracted by the force of the whole solid; the attractive force of the solid, in receding from its plane surface, will decrease in the ratio of a power, whose side is the distance of the particle from the plane, and whose index is less by three than the index of the power of the distances.

Case 1. Let LGI be the plane by which the solid is terminated. And let the solid lie on the side of the plane towards I ; and let it be resolved into innumerable planes mHM , nIN , oKO , &c. parallel to GL . And first let the attracted body C be placed without the solid. Let $CGHI$ be drawn perpendicular to those innumerable planes; and let the attractive forces of the points of the solid decrease in the ratio of a power of the distances, whose index is the number n not less by three. Therefore (by Cor. 3. Prop. XIV.) the force with which any plane mHM attracts the point C , is reciprocally as CH^{n-2} . In the plane mHM let the length HM be taken reciprocally proportional to CH^{n-2} , and that force will be as HM . In like manner, in the several planes nIN , oKO , &c. let the lengths GL , IN , KO , &c. be taken reciprocally proportional to CG^{n-2} , CI^{n-2} , CK^{n-2} , &c. and the forces of those planes will be as the lengths so taken; and therefore the sum of the forces as the sum of the lengths; that is, the force of the whole solid as the area $GLOK$, produced indefinitely towards OK . But that area, by the known methods of quadratures, is reciprocally as CG^{n-3} , and therefore the force of the whole solid is reciprocally as CG^{n-3} .

Case 2. Let the particle C be now placed on the side of the plane GL within the solid; and let the distance CK be taken equal to the distance CG . And the part of the solid LG/oKO , terminated by the parallel planes GL , oKO , will attract the particle C , placed in the middle, to neither side; the contrary actions of the opposite points mutually destroying each other by their equality. Therefore the particle C is attracted by the force only of the solid placed beyond the plane OK . But this force, by the first case, is reciprocally as CK^{n-3} ; that is, because CG , CK , are equal, reciprocally as CG^{n-3} .

Cor. 1. Hence, if the solid $LGIN$ is terminated on each side by two parallel planes LG , IN , indefinitely extended; its attractive force is known, by subtracting from the attractive force of the whole solid $LGKO$, indefinitely extended, the attractive force of the more distant part $NIKO$, indefinitely produced towards KO .

Cor. 2. If the more distant part of this indefinitely extended solid is rejected, when its attraction, compared with the attraction of the nearer part, is inconsiderable, the attraction of that nearer part, by increasing the distance, will decrease nearly in the ratio of the power CG^{n-3} .

Cor. 3. And hence, if any finite body, plane on one side, attracts a particle placed opposite the middle of that plane; and the distance between the particle and the plane, compared with the dimensions of the attracting body, is very small; and the attracting body consists of homogeneous particles, whose attractive forces decrease in the ratio of any power of the distances greater than the quadruplicate; the attractive force of

the whole body will decrease nearly in the ratio of a power, whose side is that very small distance, and whose index is less by three than the index of the former power. This assertion does not hold good of a body consisting of particles, whose attractive forces decrease in the ratio of the triplicate power of the distances. Because, in this case, the attraction of the more distant part of the indefinitely extended body, in the second Corollary, is always indefinitely greater than the attraction of the nearer part.

The important investigations of Professor Playfair, respecting the solids of greatest attraction, were suggested by the experiments of Dr Maskelyne and Mr Cavendish to ascertain the density of the earth. In determining the figure which a given quantity of matter ought to have, in order to attract a particle in a given direction with the greatest possible force, Mr Playfair has obtained results remarkable for their simplicity, and highly interesting from their connection with experimental inquiries. In order to correct the conclusions obtained by Dr Hutton from Dr Maskelyne's observations, by taking into account the unequal density of the mountain, the methods of Dr Hutton could not always be pursued. This inconvenience Mr Playfair has remedied by the propositions respecting the attraction of a half or quarter cylinder on a particle placed in its axis. The elegance of the solutions, and the address with which Mr Playfair has conducted the whole of the investigation, will appear from the following propositions, which are selected from his paper on the *Solids of Greatest Attraction*, with the kind permission of that able mathematician.

To find the solid into which a mass of homogeneous matter must be formed, in order to attract a particle given in position, with the greatest force possible, in a given direction.

Let A (Fig. 1. Plate L.) be the particle given in position, AB the direction in which it is to be attracted; and $ACBH$ a section of the solid required, by a plane passing through AB .

Since the attraction of the solid is a maximum, by hypothesis, any small variation in the figure of the solid, provided the quantity of matter remain the same, will not change the attraction in the direction AB . If, therefore, a small portion of matter be taken from any point C , in the superficies of the solid, and placed at D , another point in the same superficies, there will be no variation produced in the force which the solid exerts on the particle A , in the direction AB .

The curve ACB , therefore, is the locus of all the points in which a body being placed, will attract the particle A in the direction AB , with the same force.

This condition is sufficient to determine the nature of the curve ABC . From C , any point in that curve, draw CE perpendicular to AB ; then if a mass of matter placed at C be called m^3 , $\frac{m^3}{AC^2}$ will be the attraction of

that mass on A , in the direction AC , and $\frac{m^3 \times AE}{AC^3}$ will be its attraction in the direction AB . As this is constant, it will be equal to $\frac{m^3}{AB^2}$, and therefore $AB^2 \times AE = AC^3$.

All the sections of the required solid, therefore, by planes passing through AB , have this property, that

$AC^3 = AB^2 \times AE$; and as this equation is sufficient to determine the nature of the curve to which it belongs, therefore all the sections of the solid, by planes that pass through AB , are similar and equal curves; and the solid of consequence may be conceived to be generated by the revolution of ACB , any one of these curves, about AB as an axis.

The solid so generated may be called the *solid of greatest attraction*; and the line ACB the *curve of equal attraction*.

To find the equation between the co-ordinates of ACB , the curve of equal attraction.

From C (Fig. 1.) draw CE perpendicular to AB ; let $AB = a$, $AE = x$, $EC = y$. We have found $AB^2 \times AE = AC^3$, that is, $a^2 x = (x^2 + y^2)^{\frac{3}{2}}$, or $a^4 x^2 = (x^2 + y^2)^3$, which is an equation to a line of the 6th order.

To have y in terms of x , $x^2 + y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}}$, $y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, and $y = x^{\frac{1}{3}} \sqrt{a^{\frac{4}{3}} - x^{\frac{4}{3}}}$.

Hence $y = 0$, both when $x = 0$, and when $x = a$. Also if x be supposed greater than a , y is impossible. No part of the curve, therefore, lies beyond B .

The parts of the curve on opposite sides of the line AB , are similar and equal, because the positive and negative values of y are equal. There is also another part of the curve on the side of A , opposite to B , similar and equal to ACB ; for the values of y are the same whether x be positive or negative.

The curve may easily be constructed without having recourse to the value of y just obtained.

Let $AB = a$, (Fig. 1.) $AC = z$, and the angle $BAC = \phi$. Then $AE = AC \times \cos. \phi = z \cos. \phi$, and so $a^2 z \cos. \phi = z^3$, or $a^2 \cos. \phi = z^2$; hence $z = a \sqrt{\cos. \phi}$.

From this formula a value of AC or z may be found, if ϕ or the angle BAC be given; and if it be required to find z in numbers, it may be conveniently calculated from this expression. A geometrical construction may also be easily derived from it. For if with the radius AB , a circle BFH be described from the centre A ; if AC be produced to meet the circumference in F , and if FG be drawn at right angles to AB , then $\frac{AG}{AB} = \cos.$

ϕ , and so $z = a \times \sqrt{\frac{AG}{AB}} = \sqrt{AB \times AG} = AC$.

Therefore, if from the centre A , with the distance AB , a circle BFL be described, and if a circle be also described on the diameter AB , as AKB , then drawing any line AF from A , meeting the circle BFH in F , and from F letting fall FG perpendicular on AB , intersecting the semicircle AKB in K ; if AK be joined, and AC made equal to AK , the point C is in the curve.

For $AK = \sqrt{AB \times AG}$, from the nature of the semicircle, and therefore $AC = \sqrt{AB \times AG}$, which has been shewn to be a property of the curve. In this way, any number of points of the curve may be determined; and the *solid of greatest attraction* will be described, as already explained, by the revolution of this curve about the axis AB .

To find the area of the curve ACB .

1. Let ACE , AFG (Fig. 2.) be two radii, indefinitely near to one another, meeting the curve ACB in C and F , and the circle described with the radius AB , in E and G . Let $AC = z$ as before, the angle $BAC = \phi$, and $AB = a$. Then $GE = a \phi$, and the area $AGE = \frac{1}{2} a^2 \phi$, and

since $AE^2 : AC :: \text{Sect. } AEG : \text{Sect. } ACF$, the sector $ACF = \frac{1}{2} z^2 \phi$. But $z^2 = a^2 \cos. \phi$, (Prop. II.) whence the sector ACF , or the fluxion of the area $ABC = \frac{1}{2} a^2 \phi \cos. \phi$, and consequently the area $ABC = \frac{1}{2} a^2 \sin. \phi$, to which no constant quantity need be added, because it vanishes when $\phi = 0$, or when the area ABC vanishes.

The whole area of the curve, therefore, is $\frac{1}{2} a^2$, or $\frac{1}{2} AB^2$; for when ϕ is a right angle, $\sin. \phi = 1$. Hence the area of the curve on both sides of AB is equal to the square of AB .

2. The value of x when y is a maximum, is easily found. For when y , and therefore y^2 is a maximum, $\frac{2}{3} a^{\frac{4}{3}} x^{-\frac{1}{3}} = 2x$, or $3x^{\frac{4}{3}} = a^{\frac{4}{3}}$, that is $x = \frac{a}{3} = \frac{a}{\sqrt[3]{27}}$.

Hence, calling b the value of y when a maximum,

$b^2 = a^{\frac{4}{3}} \times \frac{a^{\frac{2}{3}}}{27^{\frac{1}{6}}} - \frac{a^2}{27^{\frac{1}{2}}} = a^2 \left(\frac{27^{\frac{1}{3}} - 1}{27^{\frac{1}{2}}} \right) = \frac{2a^2}{\sqrt{27}}$, and so

$b = a \frac{\sqrt{2}}{\sqrt[4]{27}}$, and therefore, $a : b :: \sqrt{27} : \sqrt{2}$, or as 11 : 7 nearly.

3. It is material to observe, that the radius of curvature at A is infinite. For since $y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, $\frac{y^2}{x} = \frac{a^{\frac{4}{3}}}{x^{\frac{1}{3}}} - x$. But when x is very small, or y indefinitely near to A , $\frac{y^2}{x}$ becomes the diameter of the circle having the same curvature with ACB at A , and

when x vanishes, this value of $\frac{y^2}{x}$, or $\frac{a^{\frac{4}{3}}}{x^{\frac{1}{3}}}$, becomes infinite, because of the divisor $x^{\frac{1}{3}}$ being in that case $= 0$. The diameter, therefore, and the radius of curvature at A are infinite. In other words, no circle, having its centre in AB produced, and passing through A , can be described with so great a radius, but that, at the point A , it will be within the curve of equal attraction.

The solid of greatest attraction, then, at the extremity of its axis, where the attracted particle is placed, is exceedingly flat, approaching more nearly to a plane than the superficies of any sphere can do, however great its radius.

4. To find the radius of curvature at B , the other extremity of the axis, since $y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, if we divide by $a - x$, we have $\frac{y^2}{a - x} = \frac{a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2}{a - x}$. But at B , when $a - x$, or the abscissa reckoned from B vanishes, $\frac{y^2}{a - x}$ is the diameter of the circle having the same curvature with ACB in B . But when $a - x = 0$, or $a = x$, both the numerator and denominator of the fraction $\frac{a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2}{a - x}$ vanish, so that its ultimate value does not appear. To remove this difficulty, let $a - x = z$, or $x = a - z$, then we have

$y^2 = a^{\frac{4}{3}} (a - z)^{\frac{2}{3}} - (a - z)^2$. But when z is extremely small, its powers, higher than the first, may be rejected; and therefore $(a - z)^{\frac{2}{3}} = a^{\frac{2}{3}} \left(1 - \frac{z}{a} \right)^{\frac{2}{3}} = a^{\frac{2}{3}} \left(1 - \frac{2z}{3a} \right)$, &c.)

Therefore the equation to the curve becomes, in this case,
 $y^2 = a^{\frac{4}{3}} \times a^{\frac{2}{3}} \left(1 - \frac{2z}{3a}\right) - a^2 + 2az = a^2 - \frac{2}{3}az - a^2 + 2az = \frac{4}{3}az.$

Hence $\frac{y^2}{2z}$, or the radius of curvature at B $= \frac{2}{3}a$. The curve, therefore, at B falls wholly without the circle BKA, described on the diameter AB, as its radius of curvature is greater. This is also evident from the construction.

To find the force with which the solid above defined attracts the particle A in the direction AB.

Let *b* (Fig. 2.) be a point indefinitely near to B, and let the curve *Ac b* be described similar to ACB. Through C draw CcD perpendicular to AB, and suppose the figure thus constructed to revolve about AB; then each of the curves ACB, *Ac b* will generate a solid of greatest attraction; and the excess of the one of these solids above the other will be an indefinitely thin shell, the attraction of which is the variation of the attraction of the solid ACB, when it changes into *Ac b*.

Again, by the line DC, when it revolves along with the rest of the figure about AB, a circle will be described; and by the part C *c*, a circular ring, on which, if we suppose a solid of indefinitely small altitude to be constituted, it will make the element of the solid shell AC*c*. Now the attraction exerted by this circular ring upon A, will be the same as if all the matter of it were united in the point C, and the same, therefore, as if it were all united in B.

But the circular ring generated by C*c*, is $= \pi (DC^2 - Dc^2) = 2\pi DC \times Cc$. Now $2DC \times Cc$ is the variation of y^2 , or DC^2 , while DC passes into D*c*, and the curve BCA into the curve *bcA*; that is $2DC \times Cc$ is the fluxion of y^2 , or of $a^{\frac{4}{3}}x^{\frac{2}{3}} - x^2$, taken on the supposition that x is constant and a variable, viz. $\frac{4}{3}a^{\frac{1}{3}} \times x^{\frac{2}{3}}$. Therefore the space generated by C*c* $= \frac{4\pi}{3} a^{\frac{1}{3}} x^{\frac{2}{3}} a$.

If this expression be multiplied by x , we have the element of the shell $= \frac{4\pi}{3} a^{\frac{1}{3}} x^{\frac{2}{3}} ax$.

In order to have the solidity of the shell ACB*bc*, the above expression must be integrated relatively to x , that is, supposing only x variable, and it is then $\frac{3}{5} \times \frac{4\pi}{3} a^{\frac{1}{3}} x^{\frac{5}{3}} a + C$. But $C=0$, because the fluent vanishes when x vanishes, therefore the portion of the shell AC*c* $= \frac{4}{5} a^{\frac{5}{3}} x^{\frac{1}{3}} a$, and when $x=a$, the whole shell $= \frac{4\pi}{5} a^2 a$.

Now, if the whole quantity of matter in the shell were united at B, its attractive force exerted on A would be the same with that of the shell; therefore the whole force of the shell $= \frac{4\pi}{5} a$. The same is true for every other indefinitely thin shell into which the solid may be supposed to be divided; and therefore the whole attraction of the solid is equal to $\frac{4\pi}{5} a$, supposing a variable, that is $= \frac{4\pi}{5} a$.

Hence we may compare the attraction of this solid with that of a sphere of which the axis is AB, for the attraction of that sphere $= \frac{\pi}{6} a^3 \times \frac{4}{a^2} = \frac{2\pi}{3} a$. The attraction of the solid ADBH, (Fig. 1.) is, therefore, to that of the sphere on the same axis as $\frac{4\pi}{5} a$ to $\frac{2\pi}{3} a$, or as 6 to 5.

To find the content of the solid ADBH, we need only integrate the fluxionary expression for the content of the shell, viz. $\frac{4\pi}{5} a^2 a$. We have then $\frac{4\pi}{15} a^3$ the content of the solid ADBH. Since the solidity of the sphere on the axis a is $= \frac{\pi}{6} a^3$, the content of the solid ADBH is that of the sphere on the same axis as $\frac{4\pi}{15} a^3$ to $\frac{\pi}{6} a^3$; that is, as $\frac{4}{15}$ to $\frac{1}{6}$, or as 8 to 5.

It has been supposed in the preceding investigation, that the particle on which the solid of greatest attraction exerts its force is in contact with the solid. Let it now be supposed, that the distance between the solid and the particle is given; the solid being on one side of a plane, and the particle at a given distance from the same plane on the opposite side. The mass of matter which is to compose the solid being given, it is required to construct the solid.

Let the particle to be attracted be at A. (Fig. 3.), from A draw AA' perpendicular to the given plane, and let EF be any straight line in that plane, drawn through the point A'; it is evident that the axis of the solid required must be in AA' produced. Let B be the vertex of the solid, then it will be demonstrated, as has been done above, that this solid is generated by the revolution of the curve of equal attraction, that of which the equation is $y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, about the axis of which one extremity is at A, and of which the length must be found from the quantity of matter in the solid.

The solid required, then, is a segment of the solid of greatest attraction, having B for its vertex, and a circle, of which A'E or A'F is the radius, for its base.

To find the solid content of such a segment, CD being $= y$, and AC $= x$, we have $y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, and $\pi y^2 x = \pi a^{\frac{4}{3}} x^{\frac{2}{3}} x - \pi x^2 x =$ the cylinder, which is the element of the solid segment.

Therefore $\int \pi y^2 x$, or the solid segment intercepted between B and D must be $\frac{5}{3} \pi a^{\frac{4}{3}} x^{\frac{5}{3}} - \frac{1}{3} \pi x^3 + C$. This must vanish when $x=a$, or when C comes to B, and therefore $C = -\frac{4\pi}{15} a^3$. The segment, therefore, intercepted between B and C, the line AC being x , is $\frac{4\pi}{15} a^3 - \frac{5\pi}{5} a^{\frac{4}{3}} x^{\frac{5}{3}} + \frac{\pi}{3} x^3$.

This also gives $\frac{4\pi}{15} a^3$, for the content of the whole solid, when $x=0$, the same value that was found by another method at Prop. II.

Now, if we suppose x to be $= AA'$, and to be given $= b$, the solid content of the segment becomes $\frac{4\pi}{15} a^3 -$

$\frac{3}{5} \pi a^{\frac{4}{3}} b^{\frac{5}{3}} + \frac{\pi}{3} b^3$, which must be made equal to the given solidity, which we shall suppose $= m^3$, and from this equation a , which is yet unknown, is to be determined. If, then, for $a^{\frac{1}{3}}$ we put u , we have $\pi \left(\frac{4}{15} u^9 - \frac{3}{5} b^{\frac{5}{3}} u^4 + \frac{1}{3} b^3 \right) = m^3$, or $\frac{4}{15} u^9 - \frac{3}{5} b^{\frac{5}{3}} u^4 = \frac{m^3}{\pi} - \frac{1}{3} b^3$ and $u^9 - \frac{9}{4} b^{\frac{5}{3}} u = \frac{15m^3}{4\pi} - \frac{15}{12} b^3$.

The simplest way of resolving this equation would be by the rule of false position. In some particular cases, it may be resolved more easily; thus, if $\frac{15m^3}{\pi}$

$$-\frac{15}{12} b^3 = 0, u^9 - \frac{9}{4} b^{\frac{5}{3}} u^4 = 0, \text{ and } u^5 = \frac{9}{4} b^{\frac{5}{3}}, \text{ that is, } a^{\frac{5}{3}} = \frac{9}{4} b^{\frac{5}{3}} \text{ or } a = b \times \left(\frac{9}{4} \right)^{\frac{3}{5}} = b \sqrt[5]{\frac{729}{64}}.$$

1. If it be required to find the equation to the superficies of the solid of greatest attraction, and also to the sections of it parallel to any plane passing through the axis, this can readily be done by help of what has been demonstrated above.

Let AHB (Fig. 4.) be a section of the solid, by a plane through AB its axis. Let G be any point in the superficies of the solid, GF a perpendicular from G on the plane AHB, and FE a perpendicular from F on the axis. Let $AE = x, EF = z, FG = v$, then x, z , and v are the three co-ordinates by which the superficies is to be defined. Let $AB = a, EH = y$, then, from the nature of the curve AHB, $y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$. But because the plane GEH is at right angles to AB, G and H are in the circumference of a circle, of which E is the centre; so that $GE = EH = y$. Therefore $EF^2 + FG^2 = EH^2$, that is, $z^2 + v^2 = y^2$, and by substitution for y^2 in the former equation, $z^2 + v^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, or $(x^2 + z^2 + v^2)^3 = a^4 x^2$, which is the equation to the superficies of the solid of greatest attraction.

2. If we suppose EF, that is z , to be given $= b$, and the solid to be cut by a plane through FG and CD, (CD being parallel to AB,) making on the surface of the solid the section DGC; and if AK be drawn at right angles to AB, meeting DC in K, then we have, by writing b for z in either the preceding equations, $b^2 + v^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, and $v^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2 - b^2$ for the equation of the curve DGC, the co-ordinates being GF and FK, because FK is equal to AE or x .

This equation also belongs to a curve of equal attraction; the plane in which that curve is being parallel to AB, the line in which the attraction is estimated, and distant from it by the space b .

Instead of reckoning the abscissa from K, it may be made to begin at C. If AL or $CK = h$, then the value of h is determined from the equation $b^2 = a^{\frac{4}{3}} h^{\frac{2}{3}} - h^2$, and if $x = h + u$, u being put for CF, $v^2 = a^{\frac{4}{3}} (h + u)^{\frac{2}{3}} - (h + u)^2 - a^{\frac{4}{3}} h^{\frac{2}{3}} + h^2$, or $v^2 + (h + u)^2 + b^2 = a^{\frac{4}{3}} (h + u)^{\frac{2}{3}}$ or, $(v^2 + (h + u)^2 + b^2)^3 = a^4 (h + u)^2$.

When b is equal to the maximum value of the ordinate EH, (Prop. III. 2.) the curve CGD goes away into a point; and if b be supposed greater than this, the equation to the curve is impossible.

The solid of greatest attraction may be found, and its

properties investigated, in the way that has now been exemplified, whatever be the law of the attracting force. It will be sufficient, in any case, to find the equation of the generating curve, or the curve of equal attraction.

Thus, if the attraction which the particle C (Fig. 1.) exerts on the given particle at A, be inversely as the m power of the distance, or as $\frac{1}{AC^m}$, then the attraction in the direction AE will be $\frac{AE}{AC^{m+1}}$, and if we make this $= \frac{1}{AB^m}$, we have $\frac{AE}{AC^{m+1}} = \frac{1}{AB^m}$, or making $AE = r, EC = y$, and $AB = a$, as before, $\frac{x}{(x^2 + y^2)^{\frac{m+1}{2}}} = \frac{1}{a^m}$, or $a^m x = (x^2 + y^2)^{\frac{m+1}{2}}$, and $x^2 + y^2 = a^{\frac{2m}{m+1}} x^{\frac{2}{m+1}}$, or $y^2 = a^{\frac{2m}{m+1}} x^{\frac{2}{m+1}} - x^2$.

If $m = 1$, or $m + 1 = 2$, this equation becomes $y^2 = ax - x^2$, being that of a circle of which the diameter is AB. If, therefore, the attracting force were inversely as the distance, the solid of greatest attraction would be a sphere.

If the force be inversely as the cube of the distance, or $m = 3$, and $m + 1 = 4$, the equation is $y^2 = a^{\frac{3}{2}} x^{\frac{1}{2}} - x^2$, which belongs to a line of the 4th order.

If $m = 4$, and $m + 1 = 5$, the equation is $y^2 = a^{\frac{8}{5}} x^{\frac{2}{5}} - x^2$; which belongs to a line of the 10th order.

In general, if m be an even number, the order of the curve is $m + 1 \times 2$; but if m be an odd number, it is $m + 1$ simply.

In considering the attraction of mountains in such a manner as to make a due allowance for the heterogeneity of the mass, it is necessary to determine the attraction of a half cylinder, or of any sector of a cylinder, on a point situated in its axis, in a given direction, at right angles to that axis. The solution of this problem is much connected with the experimental inquiries concerning the attraction of mountains, and affords examples of maxima of the kind that form the principal object of this paper. The following lemma is necessary to the solution.

Let the quadrilateral DG (Fig. 5.) be the indefinitely small base of a column DH, which has every where the same section, and is perpendicular to its base DG.

Let A be a point at a given distance from D, in the plane DG; it is required to find the force with which the column DH attracts a particle at A, in the direction AD.

Let the distance $AD = r$, the angle $DAE = \phi$, DE (supposed variable) $= y$, and let EF be a section of the solid parallel, and equal to the base DG; and let the area of DG $= m^2$.

The element of the solid DF is $m^2 y$; and since DE, or $y = r \tan. \phi$, $\dot{y} = r \tan. \dot{\phi} = r \frac{\dot{\phi}}{\cos. \phi}$, so that the ele-

ment of the solid $= m^2 r \frac{\dot{\phi}}{\cos. \phi^2}$.

This quantity divided by AE^2 , that is, since $AE : AD :: 1 : \cos. \phi$, by $\frac{r^2}{\cos. \phi^2}$, gives the element of the

attraction in the direction AE equal to $\frac{m^2 r \dot{\phi}}{\cos. \phi^2} \times \frac{\cos. \phi^2}{r^2} = \frac{m^2 \dot{\phi}}{r}$. To reduce this to the direction AD, it must be multiplied into the cosine of the angle DAE or ϕ , so that the element of the attraction of the column in the direction AD is $\frac{m^2 \dot{\phi}}{r} \cos. \phi$, and the attraction itself $= \frac{m^2}{r} \int \dot{\phi} \cos. \phi = \frac{m^2}{r} \sin. \phi$.

When ϕ becomes equal to the whole angle subtended by the column, the total attraction is equal to the area of the base divided by the distance, and multiplied by the sine of the angle of elevation of the column.

If the angle of elevation be 30° , the attraction of the column is just half the attraction it would have, supposing it extended to an infinite height.

In this investigation, m^2 is supposed an infinitesimal; but if it be of a finite magnitude, provided it be small, this theorem will afford a sufficient approximation to the attraction of the column, supposing the distance AD to be measured from the centre of gravity of the base, and the angle ϕ to be that which is subtended by the axis of the column, or by its perpendicular height above the base.

Let the semicircle CBG (fig. 6.) having the centre A, be the base of a half cylinder standing perpendicular to the horizon, AB a line in the plane of the base, bisecting the semicircle, and representing the direction of the meridian; it is required to find the force with which the cylinder attracts a particle at A, in the direction AB, supposing the radius of the base and the altitude of the cylinder to be given.

Let DF be an indefinitely small quadrilateral, contained between two arches of circles described from the centre A, and two radii drawn to A; and let a column stand on it of the same height with the half cylinder, of which the base is the semicircle CBG. Let $z =$ the angle BAD, the azimuth of D; $v =$ the vertical angle subtended by the column on DE; $a =$ the height of that column, or of the cylinder, $AD = x$, AB, the radius of the base, $= r$.

By the last proposition, the column standing on DF, exerts on A an attraction in the direction AD, which

$$is = \frac{Dd \times Df}{AD} \times \sin. v.$$

$$\text{Now } Dd = \dot{x}, Df = x \dot{z}, \text{ and } Dd \times Df = x \dot{z} \dot{x}.$$

Therefore the attraction in the direction AD is $\frac{x \dot{z} \dot{x}}{x}$ $\times \sin. v = \dot{x} \dot{z} \sin. v$, and reduced to the direction AB, it is $\dot{x} \dot{z} \sin. v \times \cos. z$.

This is the element of the attraction of the cylindrical shell or ring, of which the radius is AD or x , and the thickness \dot{x} ; and therefore integrated on the supposition that z only is variable, and x and v constant, it gives $\dot{x} \sin. v \int \dot{z} \cos. z = \dot{x} \sin. v \times \sin. z$ for the attraction of the shell. When $z = 90$, and $\sin. z = 1$, we have the attraction of a quadrant of the shell $= \dot{x} \sin. v$, and therefore that of the whole semicircle $= 2 \dot{x} \sin. v$.

Next, if x be made variable, and consequently v , we have $2 \int \dot{x} \sin. v$ for the attraction of the semicylinder.

Now the angle v would have a for its sine if the radius were $\sqrt{x^2 + a^2}$, and so $\sin. v a = \frac{a}{\sqrt{a^2 + x^2}}$;

wherefore the above expression is $\int \frac{2 a \dot{x}}{\sqrt{a^2 + x^2}} = 2 a L (x + \sqrt{a^2 + x^2}) + C$; and as this must vanish when $x = 0$, $2 a L a + C = 0$, and $C = -2 a L a$, so that the fluent is $2 a L \frac{x + \sqrt{x^2 + a^2}}{a}$, which, when $x = r$, gives the attraction of the semi-cylinder $= 2 a L \frac{r + \sqrt{a^2 + r^2}}{a}$; an expression very simple, and very convenient in calculation.

It is probably needless to remark, that the logarithms meant are the hyperbolic.

The limits of our work will not permit us to give the other propositions which Mr Playfair has demonstrated. We shall endeavour, however, to present our readers with the results of his investigations.

1. The attraction of the solid of greatest attraction is to the attraction of a sphere of equal bulk as 81 to 79.

2. The cone which attracts a particle placed at its vertex with the greatest force is formed by the revolution of a right angled triangle, the hypotenuse of which makes an angle of $31^\circ 23'$ with the axis of rotation; or the cone of greatest attraction has the radius of its base nearly double of its altitude. The attraction of a cone, when a maximum, is about four-fifths of the attraction of a sphere of equal solidity.

3. A cylinder which exerts the greatest attraction on a particle at the extremity of its axis, when the radius of its base is to its altitude as $9 - \sqrt{17}$ is to 8, or as 5 to 8 nearly. The attraction of a cylinder of the preceding form is to that of a sphere of the same solid content as 1218 to 1211.4.

4. A semi-cylinder exerts the greatest attraction upon a particle situated in the centre of its base, when the altitude of the semi-cylinder is to the radius of its base as 125 to 216.

5. If the oblateness of a spheroid diminish, while its quantity of matter remains the same, its attraction will increase till its oblateness vanish, and the spheroid become a sphere when the attraction at its poles becomes a maximum. If the polar axis continue to increase, the spheroid becomes oblong, and the attraction at the poles again diminishes.

6. The force with which a particle of matter is attracted by a parallelopiped, in a direction perpendicular to any of its sides, may be determined by the following rule. Multiply the sine of the greatest elevation into the sine of the greatest azimuth of the solid; the arch, of which this is the sine, multiplied into the thickness of the solid, is equal to its attraction in the direction of the perpendicular from the point attracted.

This rule will be understood from Fig. 7. where EM is the parallelopiped, having its thickness CE indefinitely small, A a particle situated without it, and AB a perpendicular to the plane CDMN. The greatest azimuth of the solid is the angle CAB, and its sine is $\frac{BC}{AC}$. The greatest elevation of the solid is the angle

$$BAL, \text{ and its sine is } \frac{BL}{AL}.$$

7. If a particle A gravitate to a rectangular plane, or to a solid indefinitely thin, contained between two paral-

1el rectangular planes, its gravitation in the line perpendicular to those planes will be equal to the thickness of the solid multiplied into the area of the spherical quadrilateral, subtended by either of those planes at the centre A, or to the area of the spherical figure which the plane figure subtends at that distance.

8. An isosceles pyramid, with a square base, will attract a particle at its vertex with the greatest force, when the inclination of the opposite planes to one another is an angle of 153° .

9. The force F which a parallelepiped BF exerts upon a particle A, in a direction perpendicular to its sides, is $F = \eta a - \eta' a' + BE$. $\text{Log.} \frac{(AF+FN)AE}{(AD+DE)AN} + BC$. $\text{Log.} \frac{(AF+FM)AC}{(AD+DC)AM}$: where η is the measure of the angular space, subtended at A by the rectangle BD, and η' the angular space subtended by the rectangle RF; and $AB = a$, and $AK = a'$.

"This investigation," says Mr Playfair, "points at the method of finding the figure which a fluid, whether elastic or unelastic, would assume, if it surrounded a cubical or prismatic body by which it was attracted. It gives some hopes of being able to determine generally the attraction of solids bounded by any plane whatever; so that it may some time or other be of use in the theory or crystallisation, if indeed that theory shall ever be placed on its true basis, and founded not on an hypothesis purely geometrical, or in some measure arbitrary, but on the known principles of dynamics."—The demonstration of the preceding important results will be found in the *Transactions of the Royal Society of Edinburgh*, vol. vi. p. 187. (o).

ATTRACTION AND REPULSION OF FLOATING BODIES. See **FLOATING BODIES**.

ATTRIBUTES. See **LOGIC, GOD, and THEOLOGY**.

ATTRITION. See **FRICTION and MECHANICS**.

ATWOOD, GEORGE, F. R. S. a celebrated mathematician, and natural philosopher, was born in the year 1745. After receiving his education at Westminster-school, he went to Cambridge, where he was for some time a tutor, and afterwards a fellow of Trinity college. The lectures on experimental philosophy which he read to the university were much admired; and it was on this occasion that Mr Atwood attracted the attention of Mr Pitt, who happened to be one of his auditors. When this statesman came into power, he conferred a sinecure office upon Mr Atwood in 1781, and employed him in all his financial calculations. Mr Atwood invented a very ingenious machine for exhibiting the phenomena of accelerated and retarded motion, and for ascertaining in a simple manner the quantity of matter moved, the moving force, the space described, the time of description, and the velocity acquired. It may be employed also in estimating the velocities communicated by the percussion of elastic and non-elastic bodies, for determining the resistance of fluids, and for confirming the properties of rotatory motion. His principal works are, his *Description of Experiments*; his *Analysis of a Course of Lectures*; his *Treatise on Rectilineal and Rotatory Motion*; his *Treatise on Arches*, 1801; and his *Disquisition on the Stability of Ships*, in the *Phil. Trans.* for 1798.

Mr Atwood was honoured with the Copley medal for his valuable papers in the *Transactions of the Royal Society*. He died in London on the 11th July 1807, in

VOL. III. PART. I.

the 62d year of his age, and was interred in St Margaret's church, Westminster. (j)

AVA, KINGDOM OF. See **BIRMAN EMPIRE**.

AVA, or AUNGWA, the name of the ancient capital of the Birman empire, which has been gradually falling into decay since the new capital Ummerapoora was founded. Ava is situated on the banks of the river Irrawaddy, and was divided into an upper and a lower city. The former was about four miles in circuit, and was protected with a deep ditch and a wall 30 feet high. The latter was only about a mile in circumference, but was much stronger than the lower city. Dilapidated temples, roofless houses, and streets covered with rank grass and bushes, form a striking contrast with the rising city of Ummerapoora. See Syme's *Embassy to Ava*, vol. ii. p. 270. and Rennel's *Memoir*, p. 297. See also **BIRMAN EMPIRE**, and **UMMERAPOORA**. (w)

AVAL, or AUAL, one of the Bahrin islands on the western side of the Persian Gulf. It is about 30 miles long and 12 broad, and contains, besides the fortified town of Bahrin, about 60 poor villages. Dates are produced in the island in great abundance; and the best pearls are obtained from its pearl fishery. The duty upon these articles amounts to a lack of rupees. The inhabitants of Aval are Arabs of the Chia persuasion. E. Long. $48^\circ 56'$, N. Lat. $26^\circ 45'$. See **BAHRIN**. (j)

AVALANCHES, the name given to those immense masses of snow which are precipitated from the Alps, and which often overwhelm whole villages in their destructive course. When the snow begins to melt by the heat of summer, the water which is produced runs below, and destroys the adhesion between the snow and the earth, and a new snow sometimes falling upon the older mass, increases its weight and determines its fall. These masses are often detached by the impulse of the wind; and the inhabitants of the Alps are so convinced that the least sound will produce their fall, that they take off the bells from their mules; and when the avalanches are too slow in falling at places where they are precipitated annually, the inhabitants endeavour to accelerate their fall by the report of their muskets. These avalanches sometimes occasion dreadful hurricanes. In the winter of 1769, 1770, an avalanche, produced by the immense quantity of snow which had fallen, rolled down upon the pastures on the mountain of Sixt in the Alps. The impulse which was given to the air by the fall of this huge mass was so dreadful, that it levelled with the ground a forest of beeches and firs, which covered the declivity of the mountain, stopped the course of the river Givre, which runs through the subjacent valley, and overthrew a number of trees and barns on the opposite shore of the stream.

"The snow which falls above the superior limit of congelation," says Mr Leslie, "from its powdery and incohesive quality, is incapable of much accumulation: loosened by the impression of the sun, it slides down, and gathering force in its descent, it often precipitates itself in those dangerous *avalanches*. But I consider glaciers themselves as formed only by avalanches of a rarer and more formidable kind. The icy zone will accumulate till its weight at last overcomes its cohesion; then, giving way, it will rush down the side of the mountain with irresistible sweep, and spread its shivered fragments. This statement agrees with the phenomena, and explains the reason why glaciers are not observed among the Andes." *Experimental Inquiry*, &c. note xxv. p. 537, 540. See **GLACIER**. (o)

AVARS, AVARES, or AVARI, a name denoting "far distant," was formerly applied to the inhabitants of the more remote districts of Asiatic Sarmatia, towards the east; but is now chiefly confined to a horde of barbarians belonging to the nation of the Ogors or Varchonites, who, about the middle of the sixth century, when resisting an invasion of the Turks, were defeated with the loss of their king, and 300,000 of his subjects. A few, preferring exile to servitude, wandered towards the south in quest of new settlements. Their very name inspired terror into the nations through which they passed, and, tracing the course of the Volga, they stopped not till they had pitched their tents at the foot of mount Caucasus. Here they first heard of the rich kingdoms of the West, and dispatching ambassadors to Constantinople, they proffered their services in defence of the empire, and, relying on the terror of their name, demanded as their reward, "precious gifts, annual subsidies, and fruitful possessions."—"The whole city," says Gibbon, "was poured forth to behold, with curiosity and terror, the aspect of a strange people; their long hair, which hung in tresses down their backs, was gracefully bound with ribbons, but the rest of their habit appeared to imitate the fashion of the Huns." The emperor Justinian, worn out with age, and the exertions of an arduous reign, preferred inglorious peace to a doubtful war. He received the Avars as friends and subsidiaries; and directed their arms against the enemies of Rome. With savage fury, they over-ran Germany and Poland. The banks of the Danube, and of the Elbe, were alternately covered with their tents, and many of the conquered tribes were confounded under the name and standard of the Avars. Their power was now established in Europe, and, from being the friends and allies of the Romans, they became their most determined foes. The emperor had transferred his friendship to the Turks, who, pursuing the footsteps of the vanquished Ogors, had appeared in the empire, and branded the Avars with the title of fugitives and rebels. Their embassy was now received with coldness by Justinian II.; their threats were disregarded, and their ambassadors dismissed with haughty defiance. Dreading, probably, to meet the Romans in alliance with their ancient conquerors, the Avars dissembled their resentment, but remembered the insult. Leaguings with the Lombards, they extirpated the nation of the Gepidæ, and received as the price of their alliance the country of Dacia, comprehending the fertile provinces of Wallachia, Moldavia, and Transylvania. Here they erected an empire, which subsisted with splendour for upwards of 230 years. By the departure of the Lombards for Italy, the Avars became masters of their extensive possessions; and at the beginning of the seventh century, the dominions of Baian, their chagan or king, extended from the mouth of the Danube to that of the Oder. In the plains of Hungary, he occupied the rustic palace of Attila, whose character and policy he seems to have imitated. From avarice or caprice, he harassed the empire by desolating incursions, or repeated demands of costly presents. After every inroad, the annual subsidy or tribute was increased; and he retaliated upon the successors of Justinian the insult which had been formerly offered to his countrymen. The emperor Maurice could no longer brook the insolence of the chagan, and determined to meet the barbarian in arms. In five successive battles Priscus the Roman general was victorious; 17,200 Avars were taken prisoners, and 60,000, with four sons of the chagan, fell in the field. But Pris-

cus was not allowed to follow up his success, being recalled to defend the capital of the empire. Baian now directed his steps to the fertile plains of Italy. Murder and rapine were the attendants of his march. The rights of victory were abused, and the laws of nations violated with the most wanton brutality. His captives were either slain, or reduced to servitude, and the noblest virgins were abandoned to the promiscuous lust of his barbarous followers. Unsated with blood and plunder, the Avars returned to their predatory warfare in Thrace. The emperor Heraclius attempted to buy their friendship with intreaties and 200,000 pieces of gold, but the perfidious chagan dissembled his design, and, after a fruitless attempt to surprise and take Heraclius prisoner, he entered into an alliance with Chosroes king of Persia, and threatened to annihilate the empire of the East. Constantinople was invested by 110,000 barbarians under the command of the chagan, A. D. 626. During ten successive days the assault was repeated, but a scarcity of provisions, and the determined resistance of the inhabitants, compelled the Avars to retire; and the empire was rescued from impending ruin, by the alliance of the Turks, and the bravery of Heraclius. These barbarians, however, still continued to be the scourge and terror of the surrounding nations. About the end of the 8th century, they resisted, for a time, with persevering courage and resolution, the mighty power of Charlemagne, but were at last defeated in a general engagement by Henry duke of Friuli, who took their capital Ringa, after an obstinate defence, and carried off immense treasures, the plunder of the neighbouring countries, which they had been amassing for ages. Their reduction was completed by Pepin king of Italy, who killed the chagan in battle, and put an end to the war. The remainder of this people, under their leader Thaudin, submitted to Charlemagne, were baptised, and received into his protection.

A nation of Avars, inheriting the bravery of their ancestors, exists at this day in the mountains of Daghestan. Living in tents, and wandering from place to place, they have maintained their independence, in spite of the repeated attacks of the neighbouring princes, who have often attempted to subdue them. See Gibbon's *Hist.* vol. vii. p. 261; and viii. p. 176, &c. *Mod. Un. Hist.* vol. xxiii. p. 148. (*n*)

AVATSCHA, or AWATSKA, called also *St Peter* and *St Paul*, a sea-port of Kamtschatka. It is situated upon a tongue of land, which, like an artificial bank, forms behind the town a harbour enclosed like a circle; which, during winter, might accommodate three or four dismantled ships. It was proposed by M. Kasloff, the governor, to mark out on the side of this basin the plan of a town, destined to be the capital of Kamtschatka, and perhaps the grand centre of commerce with China, Japan, the Philippines, and America. The bay of Avatscha, which was visited both by Captain Cooke and La Perouse, is represented as the most commodious and safest for shipping in the world. It has excellent holding ground, and its mouth is so narrow, that it could easily be protected by a fort. Two vast harbours, one on the east, and the other on the western coast, could contain all the ships of England and France. E. Long. 158° 48', N. Lat. 52° 51'. See La Perouse's *Voyage*, vol. ii. ch. xxii. p. 117, &c.; and the Continuation of Cooke's *Voyages*. (*n*)

AUBAINE, the name of the right, by which the French king inherited the property of every foreigner that died within his dominions. As the Scots, the Swiss,

the Savoyards, and the Portuguese, were reckoned natives of the kingdom, they were exempted from the effects of this oppressive and inhospitable custom.* See

Robertson's *Hist. Charles V.* vol. i. p. 377; and Muratori *Annali d'Italia*, vol. ii. p. 14. (π)

* By the 15th article of the Treaty of Utrecht, made in 1713, and by an edict of Louis XV. of the 19th of July, 1759, registered in Parliament the 4th of August following, all the subjects of the Crown of *Great Britain* were, and have ever since remained, exempted from the *Droit d'aubaine*. *Denisart, Collect. de Jurisf. verbo ANGLAIS*. It is astonishing that the English writers hardly ever take notice of this positive fact, notorious to all Europe, and seem to prefer indulging in loud and pathetic complaints of the oppressive and inhospitable laws of a rival nation. Every body has read and admired the celebrated apostrophe of Sterne in the first chapter of his *Sentimental journey*, which, unfounded as it is in fact, has not contributed a little to keep up that national antipathy, which has been the cause of so many wars and so much bloodshed.

It is true that this exemption did not extend to the *lands* which British subjects might acquire by purchase in that country; but it must be observed, that with respect to that kind of property, the English have also a *Droit d'aubaine*, or alien law, in consequence of which, if a foreigner purchases lands in England, they are immediately forfeited to the king, as a punishment, says a celebrated writer, for his presumption in attempting to become proprietor of a part of the national soil. 1 Black. Com. 372. The French government, therefore, could not have carried the exemption farther without requiring a reciprocal favour from that of England, which most probably it was not disposed to grant.

The term *Droit d'aubaine*, derived from *alibi natus*, may be not improperly considered as a general descriptive term, embracing all fiscal extortions, by means of which governments unjustly possess themselves of the property of foreigners. Most of those extortions, coloured with the name of *Droits*, or *rights*, owe their origin to the feudal system, which was chiefly supported by forfeitures and confiscations. The property of aliens or strangers was the first object that presented itself to the rapacity of the feudal lords, and which they thought they might seize on with greater ease and impunity than that of their own subjects. Hence a variety of alien laws, established in almost every country in Europe, which were nothing else than the *Droit d'aubaine*, differently modified, but always ending in the forfeiture of the goods or lands of aliens. Even one of the greatest of human misfortunes, shipwreck, instead of giving to the unfortunate sufferers a claim to commiseration, and obtaining for them the humane assistance which they stood so much in need of, was the foundation of a right to the barbarous sovereign of the shore on which they chanced to be stranded, to seize and confiscate the miserable remnants of their property which had escaped the fury of the winds and waves. How different this from the law of the Emperor Constantine, who ordered all shipwrecked goods to be immediately delivered to the lawful owners, without detaining the least portion of them for the benefit of his imperial treasury? "For," says he, "what right has my revenue to derive profit from the misfortune of others, and, above all, from such a dreadful calamity as shipwreck?" *Quid enim jus habet fiscus in alienâ calamitate, ut de re tam luctuosâ compendium sectetur?* Cod. xi. 5. 5.

It must be acknowledged, that in this republic there are still some traces of those barbarous customs of our European ancestors. Having adopted the common law of England as the basis of our system of jurisprudence, we have been obliged to take it with some of its feudal imperfections, on which we have not thought proper too rashly and speedily to innovate. The liability of the lands of aliens to confiscation is, therefore, still a part of our common law, though in some states it has been abolished, in others greatly modified, and in none has it been, to our knowledge, to this day carried into execution. Yet it is a notorious fact, that aliens since the revolution have purchased, and still do purchase and hold lands in the United States, almost as freely as if no such law existed, because nobody will incur the odium of enforcing a law, which is repugnant to the natural feelings of mankind.

The argument which is principally urged by the advocates of the restrictive system is, that the possession of landed property gives a certain degree of political influence to its owner, which it would be dangerous to see exercised in our country by foreigners. But it should be observed, that if the alien land-holder resides abroad, he can have no influence here; and if he had, would hardly care to exercise it, his only object being the profit which he expects to derive from his purchase; if, on the contrary, he resides upon his lands, he becomes of course attached to the country, which his labours fertilize, where his family is settled, and all his hopes are centered, and is much less dangerous, in a political point of view, than the capitalist, whose paper estate may be in a moment converted into cash, and is no solid pledge to the country at large for his good conduct. At any rate, where is the necessity of confiscating the property, when it would be sufficient to prohibit the purchase and declare the contract null and void? Why make it lawful for the alien to acquire, and punish him afterwards by the forfeiture of his land? Why keep his money, and take the property for which it was given? The Romans prohibited indeed their citizens to purchase lands out of the district in which they resided, but when they took back the lands from those who transgressed, they never failed to return the consideration. *Cod. xi. 55.*

These, and other equally cogent reasons, have, no doubt, influenced those of the United States, which, like Kentucky, have enacted laws to permit alien friends to hold lands within their territories, without restriction, and those which, like Pennsylvania, have considerably modified the ancient system. In this state, all alien friends, who declare their intention to reside in the country and become citizens, may from that moment acquire lands within this commonwealth to any amount, and all others (except alien enemies) may take real property by devise or descent, though not by contract *inter vivos*. In this manner we are gradually improving our excellent system of jurisprudence; and while we cherish those admirable features which have endeared it to us, and will, we have no doubt, perpetuate it among us to the latest posterity, we are not insensible of its defects, nor unwilling gradually and cautiously to amend them.

To return to the *Droit d'aubaine*. It was abolished in France by a decree of the national assembly of the 6th of August, 1790, confirmed by subsequent decrees

AUBE, the name of one of the departments of France, which derives its name from the river Aube, which waters it. It is bounded on the north by the department of the Marne, on the west by that of the Seine and the Marne, and by that of the Yonne; on the south, by the same departments and that of the Cote d'Or; and on the east by that of the higher Marne. The quarter of this department to the west of Troyes has received the name of *La Champagne Pouilleuse*, from its extreme sterility. The southern part of it is, on the contrary, very fertile, and produces abundance of grain and fruits. It contains 1,196,370 square acres. The forests occupy other 85 thousand hectares, which are divided equally among the nation, the communes, and individuals. Contributions in the year 1803, 2,508,574 francs. Population 240,661. Troyes is the capital of the department. (o)

AUBLETIA, a genus of plants of the class Polyanthia, and order Monogynia. See BOTANY. (π)

AUBONNE, the ALBONNA of the ancients, the name of a river, of a small town, and of a barony converted into a village in the Pays de Vaud, in Switzerland. The town, situated on the banks of the river, has the form of an amphitheatre, with a handsome castle at one end, which commands a view of the lake of Geneva, and the surrounding country. Aubonne is inconveniently situated for commerce with the neighbouring towns. It is celebrated for its fine views, and particularly for that which is seen from the place called the *Signal de Bougy*. Population 1200. E. Long. 6° 24', N. Lat. 46° 25'. See *Dict. de la Suisse*, vol. i. p. 22. (π)

AUCII, a city of France, and capital of the department of Gers, situated on a declivity of the hill near the river Gers. The streets, though narrow, are clean and well paved, and the town is adorned with several

in the following year. The king of Prussia, in consequence of this repeal, exempted the French from the effects of a similar law which existed at that time in his dominions. *Moniteur*, 20th May, 1791. The abolition of the *Droit d'aubaine* has been further confirmed by the 335th article of the French constitution of 1799, otherwise called the Consular constitution, which provides, "that aliens, whether they are or not resident in France, shall succeed to the estates of their kindred, whether aliens or Frenchmen; that they may contract for, purchase and hold estates situated in France, and dispose thereof, in the same manner as French citizens, by all the means authorized by law." No alteration appears to have been made in this respect by the organic senatus consulta of the 4th of August 1802, and 19th of May 1804, by the former of which the consular dignity was established for life, and by the latter, the present imperial government was constituted. The code Napoleon, however, without reviving the *Droit d'aubaine*, appears to have introduced into the French legislation a new principle on the subject of aliens, to wit, that of reciprocity. The 11th article (Tit. 1. chap. 1.) provides, that "aliens shall enjoy in France the same civil rights, which are or shall be granted to the French by the treaties made with the nation to which the aliens shall belong." From whence it may be inferred, that aliens are now subjected in France, when there is no treaty to the contrary, to the same disabilities, to which Frenchmen are liable in the country to which the alien belongs. Du Ponceau.

elegant modern buildings. The cathedral is a most magnificent structure, and the painted windows with which it is decorated are remarkable for the brightness of their colours. Population 7696. Distance from Paris 147 leagues south-west. E. Long. 0° 35', N. Lat. 43° 40'. (o)

AUBURN, or ALBOURNE, a town of England in Wiltshire, situated on a small river which runs into the Kennet. This town had formerly a considerable trade, but since the great fire in 1760, which destroyed 70 houses, it has fallen into decay. A considerable trade in lustrans is carried on here; and in the neighbourhood there is an extensive rabbit warren, from which great numbers are sent to London. Number of houses 280. Population 1280. See Pennant's *Tour*. (j)

AUCKLAND, or BISHOP'S AUCKLAND, a market and corporate town of England in Darlington ward, in the county of Durham. It derives its name from the number of oaks that formerly grew near it, and the word Bishop's was prefixed, from the Bishops of Durham being lords of the manor, and having a palace here. The town stands near the confluence of the rivers Wear and Wandless or Gaunless. The eminence on which it is situated is of an angular form, and is about 140 feet above the level of the plain below. There is here a large manufactory for printing cotton, muslins, and calicoes. Number of houses 408. Population 1961, of whom 331 are employed in trade. See Leland's *Itinerary*, vol. i.; and Hutchinson's *Hist. and Antiq. of the County of Durham*. (o)

AUCTION, a public sale, where every kind of property is sold to the highest bidder. The regulations respecting auctions will be found in the statutes 27 G. II. cap. 13; 17 G. III. c. 50; 19 G. III. c. 56; 27 G. III. c. 13; 29 G. III. c. 63; 32 G. III. c. 41; 37 G. III. c. 14; 38 G. III. c. 54. (j)

AUCUBA, a genus of plants of the class Monocia, and order Tetrandria. See BOTANY. (π)

AUDE, the name of one of the departments of France, which derives its name from the river Aude, which waters it. It is bounded on the north by the departments of Herault and Tarn; on the west by those of the higher Garonne and the Arriege; on the south, by the Pyrenees; and on the east, by the sea. The river Aude begins to become navigable when it is about to leave the department. At Narbonne it divides into two branches, one of which, preserving the original name, loses itself in a marsh near the coast, while the other branch, under the name of Robine, terminates near Sigean. The soil of this department is naturally fertile, but ill cultivated. The honey, but particularly that which is got near Narbonne, is particularly celebrated. The department contains 1,275,593 square acres. The forests occupy 47 or 48 thousand hectares, more than the half of which belongs to the nation; 3000 hectares belong to the communes, and the rest to individuals. Contributions in the year 1803, 2,843,809 francs. Population 226,198. Carcassonne is the capital of the department. (o)

AUDIENCE, the name of the courts of justice established by the Spaniards in America.* See Robertson's *Hist. of America*, vol. iii. p. 286. (π)

AVEBURY, or ABURY, a small village of England, in the county of Wilts, is remarkable for the remains of

* It is also the name of the districts over which those courts are established. Du Ponceau.

a druidical temple, which has engaged the researches, and puzzled the conjectures, of our most learned antiquaries. It is situated about five miles west of Marlborough, and nineteen north of Stonehenge, and it claims our attention as being one of the most stupendous monuments of British antiquity which the island affords. From the tradition of the Welch bards we learn, that Avebury was one of the three primary *Gorseddau* or supreme seats of Britain; and the great national temple, or circle of convention of the ancient Britons. Here they assembled from all quarters of the island at their solemn festivals, which were held at the solstices and the equinoxes; and hither, it is supposed, that all (even from foreign countries) who wished to be perfectly skilled in druidical science, repaired for instruction. That this was the grand metropolitan station, is rendered most probable from its magnitude, the convenience of its situation, and the various British roads which converged to this spot; as also from the vast numbers of *tumuli* or barrows, and other relics of remote antiquity, which are to be found in its neighbourhood. The temple consisted of large unhewn stones placed perpendicularly in the ground, at nearly regular distances from each other, and disposed in parallel rows and circles. Most of these stones measured from ten to nineteen feet in height above the ground, forty feet in circumference, and weighed from forty to fifty-four tons each. The principal part of the temple was surrounded by a ditch and vallum about 30 feet in height, which embraced an area of 22 acres. Within this inclosure stood a large circle consisting of 100 stones, and including two double concentric circles, composed with 88 stones, and three others called the cove, with one called the central obelisk. From the large circle proceeded two avenues, extending about a mile in length each way, and consisting of 200 stones. The one towards the south-east, called the Kennet avenue, was terminated with two concentric oval arrangements of stones; and the other, the Beckhampton avenue, towards the west, had only a single stone at the extremity. The whole work is supposed to have originally consisted of 650 stones; but most of them have been thrown down, broken to pieces, and appropriated to other purposes, and a very few now remain in their original position. As a document of British antiquity, and a singular monument of ancient customs, the temple of Avebury deserves the attention of the antiquary and historian; and we cannot but regret the heedless industry of those who have laboured to destroy these venerable vestiges of former times. See Rees' *Cyclopædia*; and Britton's *Beauties of Wiltshire*, vol. iii. (p)

AVEIRO, or BRAGANCA NOVA, a sea-port town in the province of Beira, in Portugal, situated in a flat and marshy country, at the mouth of the Vouga. "The river Vouga," says Mr Link, "flows through the town, which is still very narrow, but is adorned with a handsome quay. Near the town it divides into two branches, one to the left and southward running to the sea, the other northward to Ovar. Its trade is inconsiderable, only small boats coming to the town, nor indeed could any but small ships pass the bar, which is continually shifting. The fishing alone is worthy of notice, for Aveiro chiefly supplies the province of Beira with sardinas. Large troops of mules are continually seen carrying them into the higher parts of the province." Salt is also produced here in considerable quantities. Number of houses 1400. Population 4400. See Link's

Travels in Portugal, chap. xxviii. p. 317. W. Long 8° 38' 45", N. Lat. 40° 38' 18". (π)

AVELLINO, a town of Naples, situated in the Principato Ultra, or ulterior principality. It extends about a mile along the hollow of a hill, but is not remarkable either for good streets, or elegant public buildings. Cloth is manufactured here of various qualities and to a great extent. Wooden chairs, macaroni, and paste of various kinds, are among the other articles of its trade. The soil of the surrounding country being chiefly volcanic, produces little corn. There is, however, abundance of fruit, and particularly nuts, which grow in great quantities, and which in good years produce an income of 11,250*l*. The hazels are planted in rows, and are dressed and pruned with the greatest care. In September 1694, this town was nearly destroyed by an earthquake. Between Benevent and Avellino are the celebrated passes of the Val-di-Gargano, where the Romans were blocked up by the Samnites, A. U. 433, and compelled to pass under the yoke. Population 9000. E. Long. 14° 46', N. Lat. 40° 54'. See Rollin's *Hist. Rom.* tom. iii. p. 252; and Swinburne's *Travels*, vol. i. p. 171. (π)

AVENA, a genus of plants of the class Triandria, and order Digynia. See BOTANY. (w)

AVENCHE, the *Aventicum* of the ancients, a small town in the canton of Berne, in Switzerland, situated at the south extremity of the lake Morat, near the river Broye. Avenche seems to have been a very flourishing colony in the time of the Romans. Within a space of about five miles in circumference are discovered the foundations of walls, inscriptions, Mosaic pavements, medals, and numerous remains of architecture and sculpture in marble. A column of white marble about 60 feet high; the remains of an amphitheatre; the floor of an ancient bath, about 60 feet by 40, done in Mosaic work, and ornamented with numerous human figures, are some of the remains of its ancient magnificence. "Not far from these ruins," says Mr Coxo, "stands a column of white marble, about fifty feet in height, composed of large masses, nicely joined together without cement; near it lies a considerable fragment of defaced sculpture, which seems to have once formed part of the portal belonging to a magnificent temple. At a small distance from this column, in the high road, we observed a cornice of white marble, sculptured with urns and griffins; and as we walked through the town, we remarked several other masses of cornice, ornamented with sea-horses and urns, and some marble columns of beautiful proportions.

About a mile from Avenche, near the village of Coppet, on the other side of a little stream, which separates the canton of Friburgh from that of Berne, are the remains of a small aqueduct, discovered about fifteen years ago, by the accidental fall of a sand hill. The outside is formed of stones and mortar, and the inside of red Roman cement; the vault of the arch may be about two feet and a half high, and one and a half broad. This aqueduct has been traced to the east side of the town, and near the marble column. We were also informed that it extends to the tower of Gausa, between Vevey and Lausanne, and that between Villarsel and Marnau, about four leagues from Coppet, an arch of nearly the same dimensions is excavated in the solid rock." The emperor Vespasian was one of the principal benefactors to this colony. In an inscription preserved in the church of Avenche, it is called *Colonia Julia Flavia, equestre*

emerita, Aventicum Helveticorum federata. E. Long. 7° E, N. Lat. 46° 52'. A description and engraving of the Mosaic pavement will be found in Schmidt's *Recueil d'Antiquités de la Suisse*. See also Cox's *Travels in Switzerland*, vol. ii. p. 174—180; and *Dict. de la Suisse*, vol. i. p. 24. (o)

AVERNI, known also by the name of *Mephites*, are certain lakes, or other places, which infect the atmosphere with pestilential vapours. The most famous of these was the lake Avernus in Campania, celebrated by the ancients as the entrance into the infernal regions. It was supposed to be bottomless, and computed to be about two miles long, and one broad. Its depth, however, is now ascertained, which is in some places 188 feet. It is situated near Puzzuoli in the province of Terra di Lavoro, and is called by the modern Italians Lago d'Averno, and Lago di Tripergola. Strabo describes it as lying within the Lucrine bay, and accessible only by a narrow passage. Its steep banks were covered with impervious groves, which excluded every ray of light; and such was the poisonous quality of its water, and the virulence of the vapours which it exhaled, that all birds which attempted to fly over it sunk down dead. A gloomy cave adjoining the lake is represented by Virgil as the habitation of the Cumæan Sibyl:

Spelunca alta fuit, vastoque immanis hiatus,
 Scrupea, tuta lacu nigro nemorumque tenebris:
 Quam super haud ullæ poterant impunè volantes
 Tendere iter pennis: talis sese halitus atris
 Faucibus effundens supera ad convexa ferebat;
 Unde locum Graii dixerunt nomine Avernum.
 VIRG. lib. vi. 236.

Deep was the cave; and downward as it went
 From the wide mouth, a rocky rough descent;
 And here th' access a gloomy grove defends,
 And here th' innavigable lake extends;
 O'er whose unhappy waters, void of light,
 No bird presumes to steer his airy flight;
 Such deadly stench from the depth arise,
 And steaming sulphur, that infects the skies.
 From hence the Grecian bards their legends make,
 And give the name Avernus to the lake.

DRYDEN'S *Virg.* vol. iii. p. 122.

Here, at midnight, the trembling votaries of the Sibyl were supposed to celebrate her dismal orgies; costly sacrifices were offered to propitiate the favour of the infernal deities, and the secrets of futurity were drawn from the maddening tongue of the prophetess. This place continued to be the favourite haunt of superstition till the time of Augustus, who violated its sanctity, dissipated its poisonous exhalations, and dispelled the impenetrable darkness which enshrouded it. He cut down the surrounding wood, and, connecting it with the Lucrine lake and the sea, he formed the Julian harbour, in which he exercised his fleet, during the winter, before he led it against Sextus Pompey. (*Suet. Aug.* 16.) From the present appearance of the lake, some have been inclined to suspect the ancients of exaggeration in their account of its malignant qualities. Spallanzani affirms, that neither the lake nor its environs afford any indication of noxious exhalations; while Mr Swinburne, on the contrary, thinks them entitled to more credit; and observes, that even now the air is feverish and dangerous, as the jaundiced faces of the vine-dressers who live in the neighbourhood most ruefully testify; and Boccaccio relates, that, during his residence at the

Neapolitan court, the surface of this lake was suddenly covered with dead fish, black and singed, as if killed by some subaqueous eruption of fire. The once poisonous Avernus, however, now presents a beautiful sheet of water, clear and serene, and abounds with fish and water-fowl.

Averni are very common in Hungary, on account of its numerous mines. In Italy, the Grotto del Cane is remarkable for its poisonous steams; and the valley of Sottalata, between the lakes Agnano and Puzzuoli, derives its name from the vast quantities of sulphur which are continually forced out of its clefts by subterraneous fires. See Spallanzani's *Travels*, vol. i. p. 128, &c. Swinburne's *Travels*, vol. iii. p. 51, &c. (h)

AVERRHOA, a genus of plants of the class Decandria, and order Pentagynia. See BOTANY. (w)

AVERROES, (named by his countrymen Abual-Walid Mohammed, Ebn Achmed, Ebn Mohammed, EBN ROSHD,) the most admired of the Arabian philosophers, was born about the middle of the 12th century, at Cordova, a city of Andalusia, then the capital of the Moorish dominions in Spain. His father was the chief magistrate and supreme judge of the province, and also possessed the highest ecclesiastical authority. At an early period of life, Averröes devoted himself, with the greatest eagerness, to the study of mathematics, physics, law, and theology, and, above all, to the philosophy of Aristotle, on whose writings, though unacquainted with the Greek language, he commented so successfully, that he not only was surnamed *Commentator*, κατ' ἔξοχην, but, in the estimation of many of his contemporaries, deserved a pre-eminence of praise superior to that of the Stagirite himself. For several ages, the scholastic disputants, of every possible variety of opinion, regarded his authority as oracular; but, though he was in all cases appealed to with confidence by the contending parties, it does not appear that his Sibylline pages ever had the effect of terminating their contests, or ever contributed to soften the asperity with which their literary hostilities were conducted. He had acquired the talent of expressing himself with such ambidextrous felicity, that, whenever his words had the appearance of being intelligible, it required little ingenuity to derive from them a profusion of arguments in support of either side of the question. To this artifice, the most judicious writers have ascribed his unparalleled reputation.

By the suffrages of his fellow-citizens, he was raised to the dignified offices which had been held by his father and grandfather, in the provinces of Andalusia and Valencia. So great at this time was his reputation, that he was chosen, by the caliph Jacob Al-Mansor, to fill a similar station in Morocco, and, in the mean while, he was permitted to nominate a deputy at Cordova; to which place he returned, after having appointed subordinate judges and magistrates throughout the kingdom of Mauritania.

After being thus loaded with honours and distinction, he was destined to experience a most humiliating reverse of fortune. Having been persuaded to give lectures in philosophy to a number of young men, he incautiously advanced a variety of opinions, which could not easily be reconciled with the doctrines of the prophet. He was publicly accused of heresy, and condemned by the caliph to the severe punishment of degradation from his offices, confiscation of his whole property, and the infamy of residing in the suburbs of the city, among Jews and outcasts from the faith. After

having for some time submitted with exemplary meekness to the multiplied indignities which were heaped on him by vulgar fanatics, whose bigotry was inflamed by the malice of his private enemies, he succeeded in effecting his escape to Fez; but there he was soon detected and committed to prison. For his temerity and presumption in attempting to escape from his ignominious doom, the judges and divines, commissioned by the king to deliberate on his case, sentenced him to a most mortifying penance, which was inflicted on him with unmitigated rigour. At the time of public prayers, the prisoner was conducted to the gate of the mosque, where, in the most submissive posture, with his head uncovered, he was exposed to the grossest insults from the meanest of the people, every one of whom had the privilege of testifying his abhorrence, by spitting on the heretic's face. He then professed his contrition for his offences, and publicly recanted his errors. For some time afterwards he resided at Fez, and gave lectures on jurisprudence. He was then permitted to return to his native city, where he lived in a state of the lowest indigence, till a singular and unexpected occurrence restored him to his former honours. The person who had been promoted to the office which he had held in Morocco became obnoxious to the people. They could not fail to compare the oppression under which they groaned, with the liberal conduct of Averröes. Reflecting on the equity and clemency of his administration, they were convinced that a more discerning and a more upright magistrate could never be expected; and under the influence of this conviction, they concurred in soliciting the caliph to reinstate the man, who had long been the victim of persecution, and who at that moment was living in the most abject state of disgrace and wretchedness. The prince, after consulting the leaders of the sacerdotal order, yielded to the petition of his subjects, and Averröes again emerged from obscurity to the honourable places which he had formerly held. During the remainder of his life, he resided at Morocco, where he died about the beginning of the 13th century, probably in 1206.

The natural dispositions of Averröes are described by almost all authors as having been superlatively amiable. As a judge, he acted with uniform impartiality, prudence, and integrity, and with such gentleness and feeling, that when the laws required the punishment of death to be inflicted, he was never able to pronounce the sentence. Though born to an ample fortune, and though he enjoyed situations of great emolument, he was a pattern of frugality, moderation, and temperance. His liberality was unlimited, particularly to men of letters, whose circumstances did not enable them to gratify their inclination for study; and it was a favourite maxim of his, that wealth could never be better employed, than in converting enemies into friends. His patience and forgiveness of injuries deserve to be recorded. On a certain occasion, during a public lecture, one of his auditors went up to him, and whispered in his ear a most provoking insult. Not in the least disconcerted, the philosopher betrayed no emotion either of surprise or resentment, but merely signified, by an inclination of the head, that he had heard what was said to him. The circumstance would never have been known; but the person who had offered him the affront was so astonished at his equanimity and forbearance, that he could not refrain from making an apology more public than the offence, and testifying that no retaliation

could have mortified him so deeply as the superiority of mind evinced by Averröes.

His character as a philosopher would before this time have been forgotten, had not the extravagant encomiums of his admirers been transcribed by the historians of succeeding ages. His unbounded admiration of Aristotle is only one among many proofs of the defective erudition of the times in which he lived. The works of the Grecian philosopher and his commentators were the sole object of study, because scarcely any other writings worthy of perusal were known. These wonderful productions Averröes, who was ignorant of Greek, had no opportunity of examining, except through the medium of very incorrect translations into his native tongue; and he constantly displays an entire ignorance of the works of all other philosophers. He did not know the difference between Protagoras and Pythagoras; and the titles by which he refers to the works of Plato are perfectly ludicrous. (*Lud. Viv.*) He is generally obscure, and full of contradictions; always abundantly dogmatical, and sometimes so arrogant, that we cannot help questioning the accounts which have descended to us of his urbanity and mildness. Among other subjects, he wrote on medicine, with the theory of which he is said to have been well acquainted; but it is remarkable, that though he often combated the opinions of his predecessor and rival Avicenna, he cautiously abstained from naming him. It is understood that he contributed to eradicate some medical prejudices. It had long been an undisputed maxim, that blood-letting, if practised before the fourteenth year, invariably proves fatal. Averröes ventured to bleed a child of his own not above seven years of age, who had been seized with an inflammation of the lungs, and the experiment, having terminated happily, demonstrated the fallacy of the opinion, by which physicians had hitherto been restrained from hazarding a method of cure, which is obviously indicated by the symptoms of inflammatory diseases. The work which gained him the greatest credit was entitled *Destructiones Destructionum*, and was intended as a refutation of the errors of Algazel, who denied that the world is in any sense the work of God. This occasional defender of the faith, however, is accused of propagating heresies not less flagrant than those of Algazel. He maintained that there is only one understanding, absolutely the same, diffused among all the individuals of the human race. He rejected the Christian religion, partly on account of the mystery of the Eucharist, which he derided, (*quia Christiani genus stolidissima, Deum faciunt et comedunt*;) but his chief objection to our faith was, that it admits the creation of the world, which he pronounced an impossibility. He insisted that the divine providence cannot extend to individual objects. He believed that all spiritual existences have continued from eternity unchanged. He despised the Jewish religion as an assemblage of puerile observances; and Mahometanism he said was but a swinish faith, because it gave a free license to sensual indulgences. He denied that there could be a future state of rewards and punishments. He has often been charged with atheism; not, however, we think, with greater reason than there is to extend the accusation to Aristotle, and the other philosophers who asserted the eternity of the world; an opinion which the ancients thought consistent with theism, but which both Christians and Mahometans have concurred in reprobating as atheistical. Erasmus speaks of him with great indignation, stigmatizing him by the severe epi-

thets *imptus και της καταρατος*. Petrarch was for some time engaged in preparing a confutation of his writings.

The understandings of Albertius, Scotus, and Aquinas, must have been singularly constituted; otherwise we cannot easily account for the avidity, with which they gave their days and nights to the perusal and re-perusal of this self-contradictory author, and for that defect of perspicacity, or else that faculty of explaining things away, which saved them the horror of being shocked by the detection of his impieties.

Perhaps, however, Averrões may have been as much misrepresented by his Latin translators, as Aristotle was by his Arabian interpreters. The rabbins and schoolmen, who made his works known in Europe, were more remarkable for their zeal than for their ability; and the world is little indebted to them for the slovenly manner in which they executed their unprofitable task. See Leo Afric. *De Vir. illustr. apud Arab.* Lud. Vives *de Caus. Corrupt. Artium*. Cæli Rhodigin. *Antiq. Lect.* Hottinger. *Bibl. Theolog.* D'Herbelot, *Bibl. Orient.* Bayle *Dict. Histor. et Crit.* (z)

AVERSA, a town in the territory of Lavora, in the kingdom of Naples, built A. D. 1029, by count Rainulf, the leader of the Normans. It was called Aversa, from its opposition to Capua, and from the aversion which Rainulf felt for Pandulph, the prince of that city. The first asylum of the Normans in Italy, was a strong camp in the depth of the marshes of Campania, but, by the liberality of the Duke of Naples, Aversa was built and fortified for their use, and they enjoyed all the luxuries of that fertile district. Distance from Naples eight miles. E. Long. 14° 9', N. Lat. 40° 58'. See Gibbon's *Hist.* chap. lvi. vol. x. p. 232.

AVESNES, a strong fortified town of France, situated on the river Hispre. Its fortifications were repaired by Vauban. Population 2935. E. Long. 3° 54', N. Lat. 50° 8'. (zv)

AVEYRON, the name of one of the departments of France, which derives its name from the river Aveyron, with which it is watered. It is bounded on the north by the department of Cantal; on the west, by that of Lot; on the south, by that of Tarn; and on the east, by that of the Gard and Lozere. There is little corn in this department; but the pastures are excellent, and there is plenty of wine and hemp. Besides these productions, there are mines of lead, iron, copper, alum, and coal; and several mineral springs. A considerable trade is carried on in cattle in this department. It contains 1,767,424 square acres. The forests, which belong chiefly to individuals, occupy 59 or 60 hectares. Contributions in 1803, 3,198,633 francs. Population 328,195. Rhodéz is the capital of the department. (o)

AUGER, BORING, the name given to a very ingenious patent machine, invented by Mr Ryan, for boring through strata. The machine brings up a cylindrical portion of the rock through which it is passing, about five inches in diameter, and as it works perpendicularly, it exhibits the inclination of the strata. See *Repertory of Arts*. Other machines that have received the same name may be seen in the *Transactions of the Society for the Encouragement of Arts*, vol. i. p. 317, 320; vol. xix. p. 165. Bailey's *Machines*, vol. i. p. 159, 163. (o)

AUGITE, See ORYCTOGNOSY.

AUGMENT, in Greek grammar, is an accident of certain tenses, by which the letter ε is prefixed to the word, or the initial short vowel changed into a long one, or a diphthong into another longer one. (j)

AUGMENTATION, in the law of Scotland, is that process by which a clergyman may obtain an increase of his stipend. The power of allotting a suitable provision for the reformed clergy was originally vested in a commission of parliament, appointed by several acts of the legislature. This power was afterwards transferred, by the act 1707, c. 9. to the Court of Session; who have since sat as a commission, separate from the Court of Session, and modified stipends to the clergy, out of the tithes of the parish where each minister officiates. For an account of the different regulations respecting this process, and the subject of TITHES, in general, see that article. (z)

AUGSBURG, the *Augusta Vindelicorum* of the ancients, an ancient free imperial city of Swabia, but now incorporated with the kingdom of Bavaria, is situated in a beautiful plain near the confluence of the Lech and Werlach, about forty miles north-west of Munich, and 300 miles west of Vienna. It was once a very flourishing, large, and handsome city, a principal seat in Germany of commerce, manufactures, and the liberal arts. Its position was favourable for trade between Italy, Tyrol, Switzerland, and the northern states; and accordingly it was for many ages the grand entrepôt of the commerce carried on between the Venetian territories and the different provinces of Germany, Bohemia, and the various states which extend from the Gulf of Venice to the shores of the Baltic. Here was held the celebrated diet of the empire, by Charles V. in person, A. D. 1530, at which the confederate princes, who had a few months before protested against the acts of the imperial diet of Spire, (which had declared any religious innovations rebellion against the Germanic body,) assumed the name of *Protestants*. At this diet of Augsburg, the well-known Lutheran *Confession of Faith*, consisting of twenty-eight chapters, concerning the nature, reasons, and extent of the separation from the Romish church, was drawn up by Melancthon; presented to the emperor and all the German princes; discussed with great earnestness for many weeks; and finally considered as the code of Lutheran Protestantism in Germany. The greatest delicacy of address was requisite in managing this business. The minds of men, kept in perpetual agitation by a controversy carried on for twelve years with unparalleled acrimony, without intermission of debate, or abatement of zeal, were now inflamed to a very high degree. They were accustomed to innovations, and saw the boldest of them successful. Having not only abolished old rights, but substituted new forms in their place, they were influenced as much by attachment to the system which they had embraced, as by aversion to that which they had abandoned. This spirit, and those views, were not confined to the ecclesiastics of the new sect. Some of the most powerful princes of the empire embraced them with equal ardour. The elector of Saxony, the marquis of Brandenburg, the landgrave of Hesse-Cassel, the dukes of Lunenburg, the prince of Anhalt-Dessau, together with the deputies of fourteen imperial free cities, joined in the solemn protest alluded to, and were present at the diet of Augsburg, to enforce and maintain the confession of faith presented by the learned Melancthon.

The elector of Saxony did not allow Luther to accompany him to the diet, lest his presence should inflame the minds of the opposite party to a degree incompatible with the object for which the diet was assembled. For the same reason, he and the confederate

princes and deputies employed Melancthon, the man of the greatest learning, as well as of the most pacific and gentle spirit, among the reformers, to draw up the confession of their faith, expressed in terms as little offensive to the Roman Catholics, as a regard for truth and consistency would permit. Melancthon, who seldom suffered the rancour of controversy to envenom his style, even in writings purely polemical, executed a task so agreeable to his natural disposition with great moderation and address. The creed which he composed was read publicly in the city-hall of Augsburg, before the diet, and the catholic and protestant divines. Some of the former were appointed to examine it: they brought in their animadversions. A dispute ensued between them and Melancthon, seconded by some of his coadjutors; but though he softened some articles, made concessions with regard to others, and put the least objectionable sense upon all; though Charles V. laboured with great earnestness to reconcile the contending parties; so many marks of distinction were now established, and such insuperable barriers placed between the two churches, that all hopes of bringing about a coalition were utterly desperate, (See *Seckendorff*, lib. xi. p. 159, &c.) It was not merely the Roman Catholic party, however, to whom the proceedings of the diet of Augsburg, and the confession of faith given in by Melancthon, gave offence. A very numerous body of the Protestants themselves disapproved of the whole transaction, and separated, not only from the Catholic church for ever, but also from the Lutheran. They assumed the denomination of *Evangelical Reformed*, and are still known by that title, and constitute nearly one-third of the Protestants of all Germany.

The religious affairs of the empire remained in great confusion for twenty-five years after the dissolution of the diet of Augsburg, in 1530. Ferdinand of Austria, brother of Charles V. and to whom the emperor had procured the dignity of king of the Romans, sincerely wishing an accommodation with the Protestants, called together a new diet at Augsburg in 1555, and contrived to establish something like a religious peace in Germany. A recess was framed on the 25th of September 1555, approved of, and published with the usual formalities. It contained, among other articles, the following, which we give as a specimen of the *ne plus ultra* of the religious toleration of the age. "Such princes and cities as have declared their approbation of the confession of Augsburg, in 1530, shall be permitted to profess the doctrine, and exercise the worship, which it authorises, without interruption or molestation from the emperor, the king of the Romans, or any power or person whatsoever. The Protestants, on their part, shall give no disquiet to the princes and states who adhere to the tenets and rites of the church of Rome. For the future, no attempts shall be made towards terminating religious differences, but by the gentle and pacific methods of persuasion and conference. The popish ecclesiastics shall claim no spiritual jurisdiction in such states as receive the confession of Augsburg. Such as seized the revenues or benefices of the church, previous to the treaty of Passau, shall retain possession of them, and be liable to no prosecution in the imperial chamber on that account. The supreme civil power in every state shall have right to establish what form of doctrine and worship it shall deem proper; and if any of its subjects refuse to conform to these, shall permit them to remove with all

their effects whithersoever they shall please. If any prelate or ecclesiastic shall hereafter abandon the Romish religion, he shall instantly relinquish his diocese, or benefice, and it shall be lawful for those, in whom the right of nomination is vested, to proceed immediately to an election, as if the office were vacant by death or translation, and to appoint a successor of undoubted attachment to the ancient system."

Such are the capital articles in the famous recess of Augsburg in 1555, which was the basis of religious peace in Germany, and the bond of union among its various states, the sentiments of which are so extremely different with respect to points the most interesting and important. In our age and nation, to which the idea of toleration is familiar, and its beneficial effects well known, it may seem strange, that a method of terminating their dissensions, so suitable to the mild and charitable spirit of the Christian religion, did not sooner occur to the contending parties. But this expedient, however salutary, was so repugnant to the sentiments and practice of Christians during many ages, that it did not lie obvious to discovery. It was towards the close of the seventeenth century, before toleration, under its present form, was admitted into the republic of the United Provinces, and from thence introduced into England. Long experience of the calamities flowing from mutual persecution, the influence of free government, the light and humanity acquired by the progress of science, together with the prudence and authority of the civil magistrate, were all requisite, in order to establish a regulation so opposite to the ideas which all the different sects had adopted, from mistaken conceptions concerning the nature of religion, and the rights of truth, or which all of them had derived from the maxims of the church of Rome.

The recess of Augsburg, it is evident, was founded on no such liberal and enlarged sentiments concerning freedom of religious inquiry, or the nature of toleration. It was nothing more than a scheme of pacification, which political considerations alone had suggested to the contending parties, and regard for their mutual tranquillity and safety had rendered necessary. Of this there can be no stronger proof than an article in the recess itself, by which the benefits of the pacification are declared to extend only to the Catholics on the one side, and to such as adhered to the confession of Augsburg, in 1530, on the other. The followers of Zuinglius and Calvin remained, in consequence of that exclusion, without any protection from the rigour of the laws denounced against heretics. Nor did they obtain any legal security, until the treaty of Westphalia in 1648, near a century after this period, provided, that they should be admitted to enjoy, in as ample a manner as the Lutherans, all the advantages and protection which the recess of Augsburg affords.

The philanthropist cannot help regretting the miserable figure which human reason and human passions have made in every age, in a field where the first ought to have displayed its noblest engines, and the last to have been either absolutely subdued, or at least kept under decent controul, namely, the field of Christian controversy. In it, the *bilis theologicus* has tainted every feature of the countenance, and poisoned every feeling of the heart. Although not always armed with the scymitar of the Arabian impostor, or in a condition to propagate, by force of arms, opinions which reason rejects on any other conditions, yet Christian theologians

have raged with equal fury against their antagonists in secret, and betrayed as fience a spirit as if they had inhaled the fiery blast wafted by the lion and the tiger around the standard of Mahomet; alas, they always forgot, that "*'tis the heretic that makes the fire, not he that burns in it!*"—SHAKESPEARE.

Augsburg has declined in importance ever since the trade of Germany forsook the direction which Venice, in her better days, had given it. The rise of the Dutch commonwealth, and the corresponding influence of cities like Hamburgh, Bremen, Embden, Frankfort, &c. better situated for carrying on the commerce, which now took a westerly direction, instead of continuing in the ancient track, have proved highly injurious to this place. Yet it is still, in spite of every disadvantage, a place of some consideration, and manages a great part of the transit and banking business of Bavaria, Swabia, and the adjoining districts. There are indeed no *Fuggers* or *Welsers* now to be found in it, to lend their emperor millions of dollars on demand; nor is Augsburg the great resort of the literati of southern Germany. The business of the last mentioned order of men has dwindled into the manufacture of paltry devotional tracts for peasants and children, and the construction of coarse maps, picture-books, and toys, for the lower classes of their countrymen.

As Augsburg now constitutes a part of Bavaria, and is in every respect as dependent upon that crown as if it had never enjoyed the privileges of a free imperial city, it is needless to describe a constitution and police which were much talked of in Germany, but are now no more. The Rath-haus, or town-hall, 110 feet long, 48 broad, and 52 high; the large square, of which it forms a part; the cathedral, with its two tall spires; the public fountains, some of them said to have been built by Cæsar Augustus; the intricate gate towards the Lech; and the aqueduct which carries the water of that river into the city, in sufficient quantities to supply mills and considerable manufactories with that necessary,—are often mentioned with admiration, both by statistical writers and by travellers, as well as by the natives. But to a Briton they appear diminutive and insignificant: One of the locks of our canals, and the smallest man of war in our navy, yields a much finer display of human ingenuity and address. The manufactures are still considerable, though greatly inferior to what they were before the incorporation of the city with Bavaria. They consist of cotton-goods, tobacco or snuff, mirrors, leather, paper, carpets, gold and silver jaces, sealing-wax, cordials, jewellery, clocks and watches, stone-ware, dyeing, bleaching, and printing, besides other branches connected with these manufactures. It is probable, that, in consequence of the late acquisitions of Bavaria, and of the favourable situation of this city for the Italian trade, it may yet recover, in some degree, its former rank among the German mercantile stations. The prices of the necessaries of life are as low as in any of the larger commercial towns of the continent; and the country round about it is beautiful and fertile. The academy, or college, formerly supported by the Lutherans, is gone into decay, and has not been replaced by any other learned seminary of note; but the present monarch of the country has always manifested liberal and enlightened principles of government, and will naturally promote the improvement of the second city in his dominions.

The population of Augsburg has, since 1738, fluctuated

between 30,000 and 36,000 souls, of whom two-thirds are Roman Catholics, and the rest Protestants. Jews were not, until 1805, admitted to live within the walls; but such as carried on business there, lodged in a village half a league from the city, and paid a certain tax for liberty of trading in it through the day. The manners of the people are, like those of the principal free cities of southern Germany, compounded of the primitive ones of the imperial towns, and of the modern of Germany in general. They have afforded the German poets and novel writers abundant scope for ridicule, as we may see from the humorous works of Wieland, Illand, Schræder, La-fontaine, Kotzebue, and many others, who lash without mercy the lust of titles, the vanity, the love of scandal and detraction, the purse-pride, and absurd self-importance, and, in short, the whole *Kleinstädtisches Wesen* (little royal-burgh existence) of those free commercial towns. The foreigner, however, has usually met with much kindness and genuine hospitality among their inhabitants; and although he seldom found the light manners, and the versatile elegance of Dresden, Berlin, or Vienna, he was perhaps fully recompensed by that primeval honesty, and a something approaching to originality of character, which he looked for in vain in other parts of Germany.

Augsburg has suffered severely from military contributions during the late wars. Its ramparts and fortifications were not in condition to hold out one moment against a powerful assailant; and, accordingly, it has been for sixteen years past the drudge of Bavarian, Austrian, and French armies, in succession. It is now incorporated finally with a powerful state, and enjoys a prospect of better times. Every Briton ought to wish for its prosperity, for no where are our countrymen better received, or treated with more honourable marks of kindness and distinction. E. Long. 10° 53' 38", N. Lat. 48° 41' 22". See *Busching*; *Robertson*; *Nicolai*; *Riesbeck*; *Reichart*, &c. (J. M.)

AUGURY, an ancient mode of divination, which professes to discover the will of heaven, and the secrets of futurity, by attending to the motions and voices of birds. This superstitious art was called by the Greeks *ἰσχυρομαντεία*, or *ἡ ἐλαφιστομαντεία*, or *ἐπιωνομαντεία*; the derivation of which words is sufficiently obvious. The origin of the term *augury* is not so clearly ascertained. Festus and others have derived it *ex avium gestu, vel garritu*, from the flight or chirping of birds.* Among the many strange conjectures which etymologists have proposed on this subject, we are surprised that none of them have ever thought of *avis* and *quæro*, or of *avis* and *Car*, the name of the person, who, according to some authors, was the first teacher of the art, and from whom his posterity the Carians learned it. Or why may it not be from the Chaldaic *עגור*, the soothsayers who cut up and inspected the victims? We are rather disposed, however, to derive the word *augury* from another source, which has been overlooked by all the authors whom we have consulted, viz. the Hebrew *עגור* (*ogur*), signifying a swallow or crane; a name which might be formed by *onomatopœa*, from their peculiar cry; but which we rather think is a derivative of the verb *עגור*, to sojourn; or *עגור*, to return home. These birds of passage ap-

* M. Court de Gebelin derives it, with great plausibility, from *avium cura*, because the augurs took care of the sacred birds. DE PONCEAU.

pear to have been among the first to impress mankind with a conviction of their superior sagacity, because, at intervals wisely chosen and accurately measured, they disappear from their temporary habitations, and revisit them when the genial spring puts forth its buds, and awakes the voice of the turtle. It was remarked by Ænan, that they recognise their former nests as readily as men know their accustomed dwellings, (*την ἐκαστον καλιαν ἀναγνωρίζειν, ὡς τὴν οἰκίαν ἀνθρώποι.*) And the prophet Jeremiah, (viii. 7.) indignantly lamenting the insensibility of his countrymen, says, "The stork in the heaven knoweth her appointed times; and the turtle, and the crane, and the swallow, observe the time of their coming; but my people know not the judgment of the Lord." This circumstance, as well as the mournful twittering of these timorous and perpetually agitated birds, might inspire a belief that their departure was portentous of desolation, their approach the harbinger of gladness, and their agonising scream the sure prognostic of woe. And might not the name of these ominous creatures be readily transferred to the diviner, who ventured occasionally to visit the unseen regions of Erebus, and who, in accents more dismal than the horrific note of the owl, or the ear-piercing shriek of the bittern, muttered out his pretended expositions of the mysteries of fate?

We do not pretend to know where the art of augury took its rise. It was held in the highest estimation by the Phrygians, the Arabians, the Lycians, and all the Asiatics. The Cilicians, Pisidians, and Pamphilians, in particular, (as we are told by Cicero,) regarded it as the surest mode of predicting the things to come. It was cultivated also by the Athenians, the Lacedæmonians, and other Grecian states; and even the schools of philosophy, with scarcely an exception, gave implicit credit to its rules. The Romans borrowed it from the Etrurians, who said that it was revealed to them by Tages, a supernatural being of earthly extraction, who sprung out of a furrow, and instructed the astonished rustics in the profound *arcana* of the invisible world. By an ancient law of the Roman senate, it was decreed, that no measure of importance should be undertaken without consulting the Tuscan augurs; and whenever any prodigy occurred, it was customary to send a mission into Etruria, to obtain a solution of the phenomenon. These embassies, however, equally hazardous and inconvenient, were very far from giving satisfaction. It was therefore thought expedient to send six, or, according to other accounts, ten of the noble youth to Fesulæ, to be initiated in the principles of the art at the seminary of augurs.

Romulus and Remus were practitioners of augury. The former established the college of augurs, originally consisting of three members, to whom a fourth was added by Scævius Tullius. These four were all of patrician rank. Five plebeians were afterwards added to the number; and, in the dictatorship of Sylla, a farther addition of six was made; after which period there was no addition or reduction of the numbers. These fifteen augurs were next in dignity to the college of *pontificers*; and, though their authority was merely negative, they had it in their power to controul the highest officers of the state, and either to aid or obstruct the functions of government. Their office was held for life, and could not be forfeited by the commission of the most flagrant crimes. The robe of an augur was a mixture of purple and scarlet, named the *trabea*. He wore a conical

cap; and, when exercising the duties of his mystical function, he held in his hand the *lituus*, a staff neatly incurvated at the top. Equipped in these peculiar badges of his office, he was prepared for the solemnity of taking the auspices from the meteors of the atmosphere, and from the winged messengers of Pluto or of Jove. He walked out of the city at midnight, pitched a tent on an eminence, lay till the dawn began to brighten, and then, after offering up prayers and sacrifices, sat down with his face directed to the east, or, as others tell us, to the south. With his crooked rod he circumscribed a space in the sky, beyond which he suffered not his eyes to wander. This imaginary space, on which his attention was rivetted, was named *templum*; and hence arose the word *contemplation*, in the same manner as the term *consideration* originated from the eagerness with which the astrologer gazed on the stars. Omens on the left were generally accounted propitious by the Romans; but the Greeks thought omens on the right more favourable. The reason commonly assigned for this apparent discrepancy is, that the former looked towards the south, and the latter to the north, when they expected signs from the heavens; so that the east, the quarter whence they looked for happy omens, was to the right of the one, and to the left of the other. There were, however, no general principles followed by any set of augurs; and what, on one occasion was hailed as the most joyful omen, was, on others, deplored as the presage of inevitable misfortune. Cicero informs us, that the rules observed by him were, in many respects, diametrically opposite to those of his friend King Decius; and that the particulars, accounted the most essential by the Pamphilians and Sicilians, were unknown, or disregarded by the professors of the art at Rome.

The Roman augurs did not confine their attention to birds. There were five classes of phenomena, from which they sought information: appearances in the sky; the singing or the flight of birds; the feeding of the sacred chickens; the motions of particular quadrupeds; and the accidents called *diræ*. Lightning from the left to the right was one of the most favourable appearances which could visit them from the sky, except when it was proposed to hold the comitia. The birds from whose voice omens were taken were called *oscines*; such as the cock, the owl, and the raven: creatures whose never-ceasing volubility furnished the interpreters of their inarticulate speech with inexhaustible stores of impostures. The *præfetes* were the fowls of boldest wing, in whose flight there was supposed to be great significance, such as the hawk, the eagle, and the vulture. The sacred chickens were confined in pens, under the charge of the *pullarius*. It was a most lamentable presage, if they refused to eat; but their devouring the food set before them so eagerly as to drop part of it, was one of the most indisputable signs of good fortune, and was called *tripudium*, (or *terrificium*, from striking the ground). Their superintendent, no doubt, understood the art of eliciting hopeful or disastrous intelligence, by means of seasonable inanition or repletion. He was but a bungling *pullarius*, who could not contrive to effect a *tripudium*; and, from the artifice which he employed, arose the phrase *auspicium coactum et expressum*. A chicken, previously half starved, may be expected to stuff so voraciously, that much of the grain will escape from its beak. The omens from quadrupeds were such as a wolf on the right carrying something in

his mouth, which was favourable; a hare crossing a road,—a strange dog, especially if black, coming into a house,—both of which were portentous of evil. Among the *diræ*, it was very discouraging to spill oil, or salt, or honey; but nothing could be more lucky than the accidental spilling of wine, so as to leave an indelible stain on the garments.

These weak superstitions, contemptible as they appear to us, are not yet entirely exploded. The vulgar in every nation ascribe a wonderful degree of significance to frivolous incidents like those which have now been enumerated; and we have seen persons of considerable strength of intellect not a little agitated at the sight of a magpie, or the voice of a cricket. All the world has heard, that if a company happen to consist of thirteen, one of the number may expect soon to die; and what man or woman is ignorant of the prophetic virtue inherent in bees-wax, or mutton-fat, when moulded into the magic form of a candle? Such popular follies as these are finely ridiculed by Addison, in the 7th paper of the *Spectator*. It is no new thing, indeed, to attack them with the weapons of ridicule. In the 12th book of the *Iliad*, Hector chides Polydamas for wishing to retire from the field, because an eagle appeared in the air, carrying a bleeding serpent in his talons. After expressing his contempt for the movements of birds, whether to the right or to the left, he introduces this noble sentiment:

Ἐκ τῶν αἰχμῶν ἀριστῶς, ἀμυνεσθῆναι περὶ πατρῶς.

From chains to save his country,—to repel
Her ruthless foes, and save a falling state;
This glorious omen stimulates the brave,
Whose lofty purpose is the pledge of triumph.

Cicero also, though himself a member of the fraternity, speaks very contemptuously of their pretensions. "Where is the wonder," says he, "that a cock should be clamorous, an animal which scarcely ever ceases to strain his throat, either by night or by day? It would be a prodigy indeed, if a fish were to do 'salutation to the morn,' in a shrill canorous voice, like the crowing of a cock." After Christianity was introduced into the Roman empire, augury gradually lost its credit. It was discouraged by Gratian, and condemned by various ecclesiastical councils. In times still more modern, however, some delirious pretenders to magic, such as Michael Scott, attempted to revive and methodise the art, which had then fallen into desuetude; but, notwithstanding their efforts to save it from oblivion, augury, strictly so called, is now so completely obsolete, that its arbitrary canons are no longer interesting, except to those who delight in obscure and chaotic researches.

To account for the origin of a practice so absurd, we shall merely suggest a few familiar facts, which might be supposed to make a strong impression on unenlightened men. The instincts of many animals, and particularly of birds, must have been remarked at a very early period. Some of them, as we have already hinted, disappear regularly at certain seasons, and, when the stated period of absence has elapsed, revisit the climate which they had forsaken; thus marking the vicissitudes of the year with almost as great precision as the progress of time is measured by the heavenly luminaries. In conjecturing the cause of these alternate emigrations and returns, it was not unnatural to ascribe them, either to sagacity greater than human, or to the influence of su-

perior beings, by whose wisdom the hawk might have been taught, on the approach of winter, to "stretch her wings toward the south." In addition to the facts relating to migratory birds, men could not fail to observe such a connection between the actions of various species of fowls and subsequent variations of weather, as might seem to imply a power of foreseeing the changes which are about to take place in the state of the atmosphere. But the most impressive circumstances are those which are observed with regard to carnivorous birds, particularly their crowding from the most distant regions to the fields of slaughter, and the scenes where the pestilence is spreading its ravages. "From the crag of the rock the eagle seeketh her prey; her eyes behold afar off; her young ones also suck up blood: and where the slain are, there is she." After men have been accustomed to associate the eagle, the vulture, and the raven, with the shocking consequences of a battle, it is not wonderful that the sight of these rapacious creatures, hovering near an army, should inspire horror, and that the blood-thirsty perspicacity, which attracts them from afar, should be considered as an indication of prescience greater than human. Whenever the imagination is thus excited, the concurrence of the most fortuitous and unimportant circumstance will be apt to mislead the judgment; and whenever any erroneous conclusion gains admission into the mind, it is impossible to calculate the extreme impositions to which it may ultimately lead.

An event, favourable or unfavourable, occurring soon after any singular appearance, or after any unusual combination of circumstances, however frivolous, is probably noted as forming a link in the apparent chain; and thus the most chimerical principles are gradually established; so that what was at first nothing more than vague conjecture, comes, in the course of time, to be considered as an indisputable truth. Of these prepossessions it is not wonderful that designing men should have taken advantage, so as to convert the superstitious tendencies of the untutored mind into engines of despotic rule, and auxiliaries of passive obedience. Such also is the force of prejudice, that a delusion, once introduced, (no matter how slight its foundations,) often maintains its ground after its absurdities are exposed, and its futility demonstrated.—The augury of Romulus owed its origin to credulity; but, under his successors, it grew into a deliberate scheme of imposture, which was not effectually overturned till the light of Christianity had dispelled the gross darkness of heathenism. See *AUSPICIES* and *DIVINATION*. See also Cic. *De Div.*; *Dionys. Hal.*; *Ovid. Fast.*; *Adam's Roman Antiquities*; *De la Chausse De Pont. Max. Augur.* &c. *August. AUGUST, the name of the eighth month of the year. It was the *sextilis* of the Roman calendar; but, in consequence of several victories gained by Augustus during that month, he gave it his own name. (α)

AUGUSTA, a town situated on a peninsula on the east coast of Sicily, built near the ruins of the ancient city of Megara. In the year 1673, this town was nearly destroyed by a dreadful earthquake. One-third of the inhabitants were killed by the fall of the houses; the powder-magazine in the citadel was set on fire; and the light-house was plunged into the sea. The town is now rebuilt, according to an uniform plan, and the houses are made extremely low. A long causeway, with salt-ponds on each side, stretches across the mouth of the

peninsula; and the arm of the sea forms an admirable harbour, sheltered from the winds and the waves, and defended by three forts built on little islands. Magazines of provisions were formerly established here by the knights of Malta, for the supply of their ships. Population 16,000. E. Long. 15° 8', N. Lat. 37° 8'. See Swinburne's *Travels*, vol. iv. p. 116. (π)

AUGUSTINE, SAINT, named also *Aurélius Augustinus*, was born in the year 354, at Tagasta, a small town of Africa, in the inland part of Numidia. His father, whose name was Patricius, though possessed of little wealth, was held in considerable estimation by his fellow-citizens, and filled for some time the office of a magistrate in the town above mentioned. His mother Monica, who is represented as a woman of great piety, carefully instructed her son in the principles of Christianity, and watched his future conduct with the most anxious affection. He was sent, at an early age, to a place of public instruction, where he showed a capacity so quick as to require very little application; but, at the same time, so strong a tendency to youthful sports, as greatly tended to impede his progress in learning. He soon indicated a strong dislike to Grecian literature, but was very much interested by the perusal of the Latin mythologists, and extremely attached to all theatrical exhibitions. During a season of sickness he requested that he might be baptized; but his mother, who was well aware of his vicious propensities, and who had rather a superstitious notion, that sins were peculiarly aggravated when committed after baptism, procured the ceremony to be deferred. In 371 he was sent to Madaura to pursue his classical studies; and, after the death of his father, he was enabled, by the assistance of his friends, to visit the city of Carthage, in order to complete his education. Here he addicted himself to every species of licentiousness; became disgusted with the profession of the law, to which he had at first directed his attention; was attracted, for a time, to the study of philosophy, in consequence of perusing one of Cicero's dialogues, entitled *Hortensius*;^{*} turned from this pursuit to the examination of the sacred scriptures; but, offended by the simplicity of their style, and anxious to understand every thing by demonstration, he at length attached himself to the followers of Manichæus.† At the intreaty of his mother, who had followed him to Carthage, he returned in 374 to the place of his nativity, where he taught grammar and rhetoric, during the space of six years, with great applause. The death of an intimate friend having rendered him unhappy in that situation, he removed to Carthage in the year 380, and continued to give instructions as a rhetorician with uncommon reputation and success. Still indulging his habits of dissipation, he attached himself, about this time, with great constancy, to a concubine, by whom he had a son named Adeodatus. Becoming dissatisfied with the doctrines of his Manichæan friends, and provoked by the insolence of his pupils at Carthage, he

went to Rome in 385, with his mistress and child, leaving his mother behind, without any information of his departure. His fame spread very rapidly in this metropolis; and, by the favour of Symmachus, præfect of the city, he was appointed professor of rhetoric in Milan.

In this place, his celebrity as a teacher continued to increase, while his character was debased by his illicit indulgences. By the sermons of Bishop Ambrose, which he at first attended only for the sake of their eloquence, by a more intimate acquaintance with that eminent prelate, and by the intreaties of his mother, who had followed him to Milan, he was persuaded to abandon his Manichæan sentiments, to dismiss his concubine, and to consent to enter the married state. Before his good purposes were accomplished, however, he relapsed into his old irregularities, and formed another illicit connection. At length, having entered upon the study of Paul's epistles, and being assisted by the exhortations of a presbyter named Simplician, he resolved, after a long and hard struggle, to abandon all secular pursuits, and to devote himself to a life of devout contemplation. He relates, that he was led to this determination by a very extraordinary circumstance; that while meditating in his garden he seemed to hear a voice addressing him in these words,—“Take and read, take and read!” that, upon opening the New Testament, he was presented with this passage.—“Let us walk honestly as in the day, not in rioting and drunkenness, not in chambering and wantonness,” &c. (*Rom.* xiii. 13.); that his friend Alipius, upon hearing what had happened, pointed out, as applicable to himself, these words in the beginning of the following chapter,—“him that is weak in the faith receive you;” and requested, therefore, to be received as his fellow Christian. They retired with some friends to a residence in the country; employed a considerable time in reading and prayer; and were baptised together by Bishop Ambrose in the year 387. Augustine immediately set out for his native country; stopped at Rome on his way, where he composed a work against the Manichæans; and while waiting at Ostia for an opportunity to embark for Africa, was deprived of his constant attendant and faithful counsellor, his mother Monica. As soon as he arrived at Tagasta, he withdrew to a country residence, where he lived with a few select friends, in imitation of the first Christians, “having all things common.” After spending about three years in this manner, he went to visit a person of rank in the city of Hippo Regius. During his residence there, it happened that the priest's office was vacant, and Valerius the bishop had assembled the canons for the purpose of electing another incumbent. Augustine, having entered the church to witness the form of proceeding, was instantly presented to the bishop, by the unanimous consent of the assembly, as the fittest person to be chosen; and, in spite of all his remonstrances, was ordained a presbyter in the year 391. He still continued to follow the manner of life which he had begun in his late retreat; formed his associates into a kind of religious society; and thus at length gave rise to the Augustine Friars, or eremites of St Augustine. In 394, he had a dispute with Jerome, in which he treated his venerable opponent with so much respect, that they afterwards became very intimate friends. As Valerius was a Greek, and found considerable difficulty to speak publicly in the Latin language, he appointed

† There never was an heresiarch of the name of *Manichæus*. The founder of the sect of the Manichæans, who is here meant, was named *Manes*. He was a Persian by birth, and disseminated his doctrines in the third century after J. C. See MANES, MANICHÆANS. DU PONCEAU.

* This dialogue is not now extant.

Augustine to preach in his place, and even in his presence, though this was contrary to the custom of the African church. He signalized himself very much at a provincial council in 393, by pronouncing an exposition of the creed; and, in 395, by the influence of his friend and patron Valerius, was installed as joint bishop of the church at Hippo. He wrote much against the Manicheans, and was very successful in vindicating from their objections the authority and integrity of sacred scripture. He laboured also with great activity and ability to expose the dangerous principles of the Donatists; narrowly escaped assassination from some of that sect in 398; but was not deterred from acting a very conspicuous part in the council which was held against them at Carthage in the year 411. By a council of the African clergy in 418, he was publicly requested to refute the errors of Pelagius and Celestine; and to him is principally due the credit of having checked the progress of their opinions. In the course of this controversy, Pelagius wrote to him a very soothing and flattering epistle; in reply to which, Augustine requested him, "rather to pray to God to make him, by his grace, such as he (*i. e.* Pelagius) had described him, than to continue to describe him as he was not." In 426, in the seventy-second year of his age, he chose a person named Eradius to assist him in his public duties, and after this employed himself almost entirely in writing upon a great variety of subjects. In 430 Hippo was invested by the Vandals, and sustained a siege of fourteen months. The aged bishop resolved to share the distresses of his people, and continued to encourage them to the last. But he was soon overpowered by the excessive fatigue which he underwent, and died, with every indication of sincere penitence and fervent piety, on the 28th of August 430, in the seventy-sixth year of his age. About seven months after this event, the city of Hippo was taken and burned by the Vandals; but the library of Augustine, containing an immense number of his own writings, was carefully preserved. The most accurate and splendid edition of the works of Augustine is that which was given by the Benedictines, printed first at Paris in 1679, and afterwards at Antwerp in 1700, with some augmentation by Le Clerc, under the fictitious name of Pherconus.

The literary talents of Augustine have been estimated very high by those who were most competent to judge of the subject. "The fame of Augustine, bishop of Hippo," says Mosheim, "filled the whole Christian world, and not without reason, as a variety of great and shining qualities were united in the character of that illustrious man. A sublime genius, an uninterrupted and zealous pursuit of truth, an indefatigable application, an invincible patience, a sincere piety, a subtle and lively wit, conspired to establish his fame upon the most lasting foundations." He is blamed by the same writer, however, as deficient in solidity of judgment; as having yielded too often to the violent impulse of a warm imagination; and as ready to write upon a variety of subjects, before he had examined them with a sufficient degree of attention and diligence. The force of this censure is in some respects diminished by the opposite testimony of the candid and discriminating Lardner, who affirms, that good sense was the distinguishing part of his character as a writer; that in points which depended upon reasoning, he was as able to form a right judgment as those who have been preferred to him; and that in learning, in Greek literature, and in

critical ability, his attainments must have been much greater than has been supposed. To all these qualities, according to Erasmus, *aderat, interim, miranda quedam animi lenitas . . . quam Plato putat non ita frequenter deprehendi in his quibus contigit acrius ingenium*. With regard to his character, in a more important point of view, there is no doubt that, during the first half of his life, he was the slave of depraved passions, and of the most extravagant opinions. Of this his own *Confessions*, and every account that we have of his life, furnish the most unquestionable evidence. But we have the very same evidence to believe, that, after the time of his solemnly assuming the character of a Christian, he was as eminent for his virtues as he had formerly been for his vices; that he discharged the public duties of his clerical office with the utmost fidelity, earnestness, and affection; that, in private life, he was distinguished by humility, candour, and benevolence; that his reformation was complete, and his penitence most sincere; and that the insinuations which have been thrown out against the reality of his temperance and devotion are groundless and illiberal in the extreme. See Mosheim's *Church History*, vol. i. pt. 2. cent. 4. ch. 2.; Godeau *Hist. de l'Eglise*, vol. ii. p. 549.; vol. iii. p. 94, 280.; Lardner's *Cred.* vol. iii. p. 392.; vol. v. p. 81.; *Augustini Vita a Benedict. conscript.*; Tillemont, *Mem. Eccles.* tit. 13. (g)

AUGUSTULUS, the last of the Roman emperors in the west. See Gibbon's *Hist.* chap. 36. vol. vi. p. 186. (j)

AUGUSTUS. See OCTAVIUS.

AVICENNA, or Ibn-Sina, an Arabian physician and philosopher, was born at Bochara, about the year 978. He has been celebrated for the precocity of his talents. When he was scarcely ten, he is said to have made great proficiency in polite literature, and to have been master of the Alkoran. Abu-Abdallah, a famous lecturer in philosophy, undertook to instruct him in the art of logic; but the pupil was soon convinced of the deficiencies of his teacher, and declined receiving any farther assistance from him. With an ardour which no disappointment could quench, and with a constancy of application which never yielded to fatigue or difficulty, he successively studied mathematics, philosophy, and medicine; and, before he was seventeen years of age, no person could be found in his native city, who was capable of giving him farther instruction in any of these branches of knowledge. In the school of Bagdad, where he afterwards studied for some time, he was regarded as a prodigy of learning. He scarcely allowed himself leisure for sleep or nourishment, and, if we could credit the marvellous tales of his biographers, his mind was perpetually awake. To the difficulties which absolutely baffled his judgment during the day, he persuaded himself that he found a ready solution in his dreams. This he piously ascribed celestial illumination granted in answer to his prayers.

There is more of the romantic than of the credible in the life of Avicenna. With these hyperbolical accounts of his almost supernatural capacity, we are at a loss to reconcile the extreme difficulty which he found in comprehending the metaphysics of Aristotle. It is said, that after the astonishing progress, at which we have only hinted, he read over that work not less than forty times without understanding a word of it. We are apt to suspect, that the perspicacity of the youthful philosopher had either been prematurely dimmed, or that the boasted sciences which he had already mastered were

not very profound, if they did not enable him to divine any meaning in the pages of Aristotle. One would suppose he had been under the influence of enchantment; for it seems an Arabian manuscript, which accidentally fell into his hands, dissipated the charm in an instant. In a transport of gratitude he flew to the mosque, and offered up fervent thanksgivings to heaven for dispelling his darkness. From this moment he was consulted as an oracle, to whose sage decisions the learned, the venerable, and the aged, yielded with implicit deference, as if he had been possessed of the gift of infallibility. We speak of him while only a youth of eighteen.

His celebrity, as a man of science, was equalled by his fame as a physician. But we forbear to recite the strange adventures, which, we are told, were occasioned by the eagerness with which he was courted by different sovereigns. We believe the accounts to which we allude are almost entirely fabulous; and we are convinced that our readers will not expect us to repeat all the legendary tales which ignorance and credulity have attempted to impose on posterity. It is pretty well ascertained, that the last years of this applauded philosopher were embittered by misfortunes, the fruit of his own vices and follies; and that his days were shortened by the excesses of criminal pleasure. He died about the year 1036, in the fifty-eighth year of his age.

This man was an incongruous compound of voluptuousness and fanaticism. Devotion and sensuality occupied him by turns. His studious habits, and his attention to the affairs of state, when he acted in the capacity of grand vizier, accord ill with the accounts which have been preserved of his libertinism. His panegyrist, however, have spoken of him in a strain of admiration, which would almost persuade us that they are painting an ideal character. He wrote with great rapidity and ease; and few authors have written more. Till the time of Averröes, his books were held in the highest estimation. He wrote a great number of treatises on morals, theology, mathematics, astronomy, philology, metaphysics, logic, natural philosophy, natural history, and medicine: And, when he was only twenty-one years of age, he planned a comprehensive view of all the sciences, which, without any assistance, he soon accomplished, though it extended to twenty volumes. This work, which he named *The Utility of Utilities*, professed to be a complete Encyclopædia of human knowledge. There are some who say, that Avicenna was a mere plagiarist. So far as we have the means of judging, we do not hesitate to pronounce him a careless and hasty compiler, without taste, or judgment, or discernment; and yet we have met with some comparatively modern authors, who speak of him as a most luminous, methodical, and profound writer, who never introduces a subject without throwing new light on it, and who is so remarkable for solidity and precision, that he can never be charged either with too great diffuseness, or too great condensation.

The scholastic divines were great admirers of Avicenna, partly, we believe, because he pretended the most devoted attachment to Aristotle, and partly in consequence of his having professed sentiments differing less than any of the other Arabians from the Christian faith. On some points, however, his heterodoxy is enormous: He rejects the doctrine of grace as altogether superfluous; he admits the eternity of motion; he denies that the world could have been made without

pre-existing matter, he asserts, that nothing which is subject to change, can proceed from God; he opposes the doctrine of a particular providence,—meaning by this term the knowledge of individual objects; he maintains that the visible heavens are animated; he ascribes to angels the faculty of propagating celestial souls; and assumes it as an indisputable truth, that angelical intelligences cannot form any conception of evil. He has been celebrated as an adept in the mysteries of alchemy and the other occult sciences; and we believe that he was as much skilled in these chimerical doctrines as in any of the substantial branches of knowledge. Upon the whole, we regard him as a weak visionary, who has contributed to retard the progress of the human mind. See Hottinger. *Bib. Orient.*; Baitoloe. *Bib. Rabb.*; Lee Afr. *De Fir. illustr. AVICENNIA, a genus of plants of the class Didynamia, and order Angiospermia. See BOTANY. (W)

AVIGNON, a city of France, and capital of the department of Vaucluse, is situated on the east bank of the Rhone, and includes a circumference of about three miles and a quarter. It is surrounded with handsome battlements and turrets. The streets and houses are in general irregular and ill built, but the public edifices are solid and grand, and indicate the splendour and magnificence of its former state. The churches of Notre-Dame, and of the Cælestines, contain several monuments and paintings equal to the finest in Italy, and their valuable curiosities are particularly deserving the attention of the traveller. In Avignon they reckon seven gates, seven palaces, seven colleges, seven hospitals, and, before the revolution, it had seven monasteries, and seven nunneries. Near the Rhone is a large rock, upon which is a platform which overlooks the whole city with its environs; and across the river stand the ruinous and decayed arches of an extensive bridge, which was demolished by an inundation in 1699. About five miles from the city is the fountain Vaucluse, where Petrarch often retired to indulge his grief and hopeless passion. On the almost inaccessible extremity of a rock which overhangs the fountain, the peasants point to an ancient castle, and call it *Il Castello di Petrarca*: and in an obscure corner of the church of the Cordeliers is shown the almost defaced tomb of his Laura, and her husband Hugh de Sade. In Avignon there are a considerable number of Jews, who, when this city was under the jurisdiction of the popes, were exposed to the most oppressive restrictions. They were confined to a distinct quarter of the town, which was so crowded that they could procure accommodation only by building their houses higher; and they durst not stir from home without yellow hats, or head dresses, to distinguish them from the Christians. From these oppressions, however, they have been relieved by the annexation of Avignon to France.

In a crusade against the Albigenses, A. D. 1226, Avignon was taken by Louis VIII. king of France: and in 1273, it was ceded to the pope, with the adjoining territory, by his grandson Philip III. In 1309, Clement V. transferred the papal court from Rome to Avignon. From that time its importance began rapidly to increase. Magnificent palaces arose for the accommodation of the pope and cardinals; new luxuries were introduced, and the simple abodes of the Albigenses were now filled with the vices and corruptions of a profligate priesthood.

For 70 years the successors of St Peter had abandoned the sacred walls of the Vatican, and even after the papal see was again removed to the banks of the Tiber, Avignon continued to be the residence of a rival pope, until the accession of Martin V. in 1418. It was then erected into an archbishopric, and continued under the sovereignty of the popes till the late revolution in France, when it was declared a part of the republic. Population 30,000. E. Long. 4° 48' 25", N. Lat. 43° 56' 38". (*h*)

AVILA, a city of Spain, in the province of Old Castile. It is situated in a beautiful plain on the banks of the river Adaja, and is fortified by a wall of 9975 feet in circumference, flanked with 26 lofty turrets. Avila is the see of a bishop, suffragan of Compostella. It has a university, founded in 1445, and a manufacture of cloths which are supposed to be equal to those of Segovia. The streets are in general regular; many of the houses are stately and well built; and the surrounding country is covered with orchards and vineyards. Avila has been rendered famous in history by the deposition of Henry IV. in 1465. The Castilian nobility, indignant at the feeble and flagitious administration of this prince, and arrogating to themselves the right of sitting in judgment upon their sovereign, assembled in the plain of Avila. Having placed upon a throne an image of Henry, arrayed in all the insignia of royalty, the several charges of accusation were read, and the sentence of deposition pronounced in the presence of a numerous assembly. The image was then stripped of its robes, and tumbled headlong from the throne; and Don Alonzo, Henry's brother, was immediately proclaimed king of Castile and Leon. See Robertson's *Hist. Ch. V.* vol. i. p. 179. W. Long. 4° 35'. N. Lat. 40° 45'. (*i*)

AULUS GELLIUS, (called by some *Agellius*), a Roman author of considerable ingenuity and various learning, (*vir elegantissimi eloquii, ac multa et facunda scientiæ*; Augustin. *de Civ. Dei*, ix. v.) was born at Rome, and flourished there, as is supposed, in the time of Adrian and the Antonines.

Of his life and circumstances the commentators have been able to collect few memorials. Having acquired the elementary branches of education in his native city, under the direction of Sulpitius Apollinaris, Titus Castrius, and Antonius Julianus, he repaired to Athens, for the purpose of prosecuting his philosophical studies; and during his residence at that celebrated seat of learning and the arts, he enjoyed the advantage of a frequent and familiar intercourse with several of the most eminent literary characters of the age. In the philological and ethical sciences he made considerable progress; and it is believed he embraced the principles of his contemporary Phavorinus. After travelling through the states of Greece, he returned to Rome, and devoted himself to the profession of the law; in which he appears to have attained to respectability and eminence, and was appointed to the situation of a judge extraordinary. (*Noct. Att.* xii. 13.) The precise period of his death is uncertain.

The only work of Aulus Gellius now extant is, his *Noctes Atticæ*, which he began to write during his residence at Athens, with the view, as he informs us in his preface, of providing a proper species of entertainment for himself and his children. It is a learned and amusing miscellany, consisting of a variety of literary and philosophical anecdotes, historical and biographical no-

tices, critical and philological remarks, &c. and is of considerable value, on account of the literary incidents and observations which it contains, and the passages of ancient authors which it has preserved and illustrated. It is valuable also in respect of the occasional information which it conveys, on the subject of ancient manners, customs, and opinions.

The style of Gellius has been the subject of much controversy among the commentators and critics, who are by no means agreed, whether he ought to be ranked among the writers of the *silver* or the *brazen* age. Without pretending to enter into the merits of this learned controversy, or to detract from the epithets *luculentus*, *nitidus*, *elegantissimus*, *latinissimus*, bestowed upon this author by many eminent and judicious critics, we shall only observe, that the reader of the *Noctes Atticæ* will occasionally remark some of those peculiarities which characterise the style of the later Roman writers. Those who are desirous of obtaining farther information upon this subject may consult the preface to Mr Beloe's translation, and the authorities therein referred to; particularly, Falsterus, *De Vita et Rebus A. Gellii*, and Fabricius, *Biblioth. Lat.* vol. i. and ii.

The *Noctes Atticæ* were first printed at Rome, by Conrad Swenheim and Arnold Pannartz, in 1469. The editor was John Andreas, the learned bishop of Aleria. The most valuable of the subsequent editions are, 1. The edition of Jenson; Venice, 1472. 2. The edition of Aldus; *ibid.* 1515. 3. The edition of Henry Stephan; Paris, 1585. 4. The Elzevir edition; Amsterdam, 1651. 5. *Cum notis variorum*; Leyden, 1666. 6. *In usum Delphini*; 1681. 7. The edition of the Gronovii; Leyden, 1706. 8. Of Conradus; Leipsick, 1762.

Mr Beloe's translation, with critical and explanatory notes, was published in 1795; and will be of essential service to the student, besides being valuable to such as are deprived of the advantage of being able to peruse the original. (*z*)

AVRANCHES, the *Abricantæ* of the ancients, a very old town of France, in the department of the Channel. The cathedral, which stands on a hill, and the ruins of the castle, which are very extensive, are the only objects deserving of particular notice. Population 5410. W. Long. 1° 22' 38". N. Lat. 48° 41' 18". (*j*)

AURELIAN, one of the Roman emperors, was the son of a peasant, and a native of Sirmium in Pannonia. He entered the army as a common soldier, and was so distinguished by his extraordinary strength and courage, that he rose successively to the rank of a centurion, a tribune, the præfect of a legion, the inspector of the camp, the general of a frontier, and, at length, to the important office of commander in chief of the cavalry. He was invested with the consulship by the influence of the emperor Valerian; and married the daughter of Ulpus Crinitus, a senator of the highest rank and merit. At the death of Claudius II., who recommended him as his successor, he was saluted emperor by the army, A. D. 270; and their election was soon confirmed by the voice of the senate. Aurelian continued to reign only four years and nine months; but every instant of that short period was marked by some memorable achievement. In the course of the year 270, he put an end to the war with the Goths; and repeatedly routed the Germans, who had invaded Italy. Returning to Rome, where some disturbances had taken place during his absence, he put to death several of the senators, who had been suspected of exciting these commo-

tions; and by the severity of his conduct in this instance, estranged from himself, in a great degree, the affections of the people. After having repaired and extended the walls of the city, in the beginning of the year 271, he recovered Gaul, Spain, and Britain from the usurpation of Tebrius, governor of Aquitaine. In 272 he turned his arms against Zenobia, the celebrated queen of Palmyra, who had established a monarchy upon the ruins of the empire in the east, and had maintained her authority during the space of five or six years. He gained possession of Tyana in Cappadocia, after an obstinate resistance: and treated the inhabitants with the utmost lenity, from respect to the memory of their countryman Apollonius. Having defeated the forces of Zenobia in the neighbourhood of Antioch, he entered that place in triumph, and conciliated the citizens by the mildness of his measures. He gained a second victory near the city of Emesa; advanced, through all the obstacles of the sandy desert and plundering Arabs, to the siege of Palmyra; cut off the succours, which were sent from Persia for its relief; and at length intercepted the queen, when attempting to make her escape from the city. Her capital surrendered very soon after, upon condition that the lives of the inhabitants should be spared; but a few of the queen's ablest counsellors, among whom was the celebrated Longinus, were afterwards sacrificed at Emesa to the vengeance of the conqueror. A short time after his departure, the Palmyreans broke out into open rebellion; massacred the governor and garrison left in their city; and proclaimed a kinsman of Zenobia their sovereign. But the avenging conqueror, naturally severe, and now roused into fury by the presumption of this revolt, and the slaughter of his troops, was soon at their gates, entered the city without opposition, put the inhabitants to the sword without distinction, and reduced that short-lived metropolis to a state of ruin, from which it never recovered. After having suppressed an insurrection, which had been excited at Alexandria by an adventurer named Firmus, whom he caused to be tortured and put to death, he returned to Rome in 274, and was honoured with a more splendid triumph than had ever been witnessed even in that city of triumphs.* On this occasion, he made his captives subservient to his military glory, but afterwards treated them with the greatest humanity and kindness. He gave to Zenobia lands and possessions in the neighbourhood of Tivoli; and appointed Tetricus governor of Lucania. Out of the spoils of his victories he built a magnificent temple to the sun, in whose service his mother had been an inferior priestess, and for whose worship he always professed a peculiar veneration. He applied himself with the utmost activity, during this short period of peace, to the suppression of various abuses, the prevention of crimes, and the general reformation of manners. He remitted all the debts, which had become due, in the course of the year, from private persons to the public treasury; and, at the same time, published an act of oblivion, with respect to all crimes committed against the state, previous to that date. He increased the largesses bestowed upon the common people; and, as he was himself a plebeian, he always manifested a peculiar predilection towards that order of his subjects. The discontent, which this partiality excited among the sena-

tial and equestrian ranks, seems to have been the real cause of a very formidable insurrection, which broke out at Rome upon his attempting to restore the integrity of the coin; and which was not quelled till after a bloody engagement had been fought with the insurgents on the Calian hill. Exasperated by this unprovoked rebellion, Aurelian let loose all the natural cruelty of his disposition; and his vengeance was not satiated till he had shed a torrent of the noblest blood in the empire. One of his own nephews was involved in this bloody prosecution; and the senate was deprived of its most illustrious members. About the close of the year 274, or the beginning of 275, the emperor marched towards Persia at the head of a well-disciplined army. Suspecting one of his secretaries of extortion, he had charged him with the crime, and threatened him with punishment. The offender, whose name was Mnestheus, aware of his danger, sought safety for himself by alarming the fears of others. Counterfeiting his master's writing, he shewed to some of the principal officers of the army a list of names, which he pretended to have found in the emperor's closet, and in which they were all devoted to death. Anxious to avert this impending destruction, they instantly united with the traitor, fell upon Aurelian on the march from Byzantium, and dispatched him with many wounds. The imposition, however, was soon discovered; Mnestheus was devoted to the rage of wild beasts; and the obsequies of the emperor solemnized with the greatest pomp.

The talents of Aurelian were better suited to the command of an army, than to the government of an empire; and he acted towards his subjects more like a conqueror than a sovereign. He was unequalled in point of personal prowess; and it is affirmed that, in one engagement, he slew forty-eight of the enemy with his own hand. In order to distinguish him from another person of the same name, and in reference to his readiness for any encounter, he was called by the soldiers *Aurelianus manu in ferrum*, "Aurelian with his hand upon his sword." He exercised the strictest discipline in the army; and punished with the utmost severity every neglect of duty, or instance of licentiousness in the conduct of his troops. He was capable of great generosity; but his stern justice often degenerated into savage cruelty; and he is ranked not so much among the good, as among the useful princes. See Gibbon's *Rom. Hist.* vol. ii. p. 15—56. *Anc. Un. Hist.* vol. xv. p. 449—464. Vopiscus, *Hist. Aug.* p. 210—225. (q)

AURENG-ZEBE, or AURUNGZEBE, the Great Mogul, and a successful conqueror, was born in the year 1618. He was the third and favourite son of Shaw Jehan, whom he succeeded in the empire of Hindostan. Aureng-zebe, from his youth, seemed destined to wield the sceptre of a mighty kingdom. With a boundless ambition, lurking under the appearance of unassuming humility, he possessed talents capable of directing it to the accomplishment of its object. He was well acquainted with the customs of his country. He knew that the princes of the blood must either look to sovereignty or death. No ties of kindred or humanity could save them from this alternative; the safety of the reigning monarch requiring the extirpation of all, who by their birth or power might compete with him in the empire. To lull the jealousy and suspicions of his

* For a particular account of Aurelianus's triumph, see Vopiscus *Hist. Aug.* 220; Gibbon's *Rom. Hist.* vol. ii. p. 46.; and *Anc. Un. Hist.* vol. xv. p. 458.

elder brothers, he had assumed the habit and manners of a *Fakier*, a kind of religious mendicant. But while he was counting his beads, and appeared, to all around, indifferent about the concerns of a present world, he was devising means for procuring the interests of the nobles, and laying plans for possessing the throne. By his dutiful behaviour, and apparent submission, he had insinuated himself into the affections and esteem of his father, with whom he always held a secret correspondence. Dara, the eldest son of Shaw Jehan, alarmed at the growing interests of Aureng-zebe, and beginning to suspect that he had designs upon the throne, took every means of thwarting his plans, and was often tempted to cry out, "Of all my brothers, I fear none but this *Azmazi* (this great praying man)." Aureng-zebe had been appointed to the government of the Deccan, where he first shewed his warlike disposition, and his thirst for conquest. His first attempt was directed against the kingdom of Golconda, which he would undoubtedly have subdued, had it not been snatched out of his hands by the intrigues of Dara, who, apprehensive that such a conquest would render Aureng-zebe too powerful, persuaded Shaw Jehan to accede to an immediate peace. But the loss of territory was greatly compensated by the friendship of Meer Jumla, the greatest general of his age, who, offended at the ungrateful and unworthy treatment which he had received from the king of Golconda, his master, revolted to Aureng-zebe, and was the principal instrument in raising that prince to the throne of Delhi.

Shaw Jehan falling dangerously ill in 1656, a report of his death was spread abroad, which put the whole empire in commotion, and his sons immediately prepared for open war. All the abilities of Aureng-zebe were now called into action. He found himself unable to contend single-handed with Dara, who resided at court, and, possessing the ear of his father, could command all the resources of the empire. But what force could not obtain, might be accomplished by fraud. He wrote to his brother Morad, declaring that he, being a *Fakier*, had no desire to reign; and promising, that if he would join him with all the troops which he could raise in his government, he would place him upon the throne of Hindostan. Morad was ambitious, generous, and brave, but too imprudent and unsuspecting for the times in which he lived. Little suspecting the deceitful villainy of his brother, he immediately acceded to his wishes. They joined their forces on the banks of the *Nibidda*, and accompanied by Jumla, hastened with all expedition to Agra. The mandate of his father met Aureng-zebe on his march, intimating his perfect recovery, and forbidding him to advance. Aureng-zebe pretended that this was merely a trick of his brother Dara; he swore that the letter was a counterfeit, and that his father was really dead. The imperial army under Dara was overthrown in the plains of Samonghes, and the victorious brothers stopt not till they reached the gates of Agra. Aureng-zebe now saw a throne at his disposal. He had gained over to his interest the chief omrahs of the empire; and none were allowed to enter the presence of Shaw Jehan without his permission. At the same time, he made great protestations of affection and submission to his father, and laid all the blame of what had happened upon the ambition and evil designs of Dara. He had as yet treated Morad with the affection of a brother, and the respect of a subject, always addressing him with the title of king. But the

mask was soon to be withdrawn, and the by poetical *fakier* was to appear in his real character. Morad, having inadvertently drunk too much wine at an entertainment given by Aureng-zebe, fell asleep. While in this state, his servants were ordered to withdraw, and his sabre and poignard were secured. Aureng-zebe, who had retired early, now entered the chamber, and awakening his brother, upbraided him with his indiscretion and debauchery, so unbecoming a king; then addressing his attendants, "Take this infamous drunkard; tie him hand and foot, and throw him into that room, there to sleep out his wine." The remonstrances of Morad were ineffectual. He was carried in chains to the fortress of Gualiar, where he soon after fell a victim to the fears of his brother. By the exertions of Jumla, Dara was also reduced to submission, and afterwards murdered; and his remaining brother Suja soon experienced the same fate.

Aureng-zebe was proclaimed emperor in 1659, during the lifetime of Shaw Jehan, whose pardon and paternal blessing he had obtained by his indulgent behaviour and respectful letters, but whose death neither increased nor diminished the power of Aureng-zebe. Securely seated on the throne of Delhi, there remained no competitor to dispute with him the empire; and for a period of nearly twenty years, the profoundest tranquillity reigned throughout Hindostan. The latter part of his life, however, was spent in constant activity and alarm. The rebellion of his sons, the revolt of some of the dependent provinces, and the insurrections of the *Hindoos*, whom he attempted to convert to Mahometanism, kept him almost continually in the field for the last fifteen years of his life. During that time he quelled a rebellion of the *Rajapoots* in *Agimere*; of the *Patans* beyond the *Indus*; and of the *Jates* in *Agra*: He reduced *Bengal*; annexed to his territories the *Carнатик*, with the kingdoms of *Visiapour*, *Golconda*, and *Assam*, and extended his authority over the whole peninsula within the *Ganges*. Aureng-zebe died 27th February 1707 at *Ahmednagar*, where he had taken up his winter quarters, in the 90th year of his age, and the 50th of his reign. His body, according to his own directions, was deposited in the cell of a holy dervise, near that city, in a plain tomb, without either pomp or ornament.

Destitute of that elegance of person, and winning behaviour, which instantly attracts our regard, Aureng-zebe acquired popularity by the decency of his character and the sanctity of his life. He was of a low stature, and slender make, with a large nose, and olive complexion. When the traveller *Gemelli* saw him in 1695, he was stooping with age, and supported himself on a staff. From the severe austerity of his manners, and his zealous endeavours in the cause of religion, his memory is held in great veneration by the *Mahometans*, and numerous pilgrims resort to *Ahmednagar* to pay their devotions at his tomb.

The character of Aureng-zebe has been drawn in very different colours. While some have represented him as a monster of cruelty, who waded to the throne through the blood of his family; who persecuted an inoffensive people from bigotry and hypocrisy; and whose remorse for his crimes was the bane of his future life: he has been painted by others as the greatest warrior and statesman which India ever produced; as having raised Hindostan to its highest glory; and as having lived and ruled for the happiness of his people. For

our part, we agree implicitly with neither; and when we attempt to rescue his memory from the calumnies of the one, we must not be understood as acceding to the commendations of the other. In the government of Hindostan, where the succession to the throne is undecided by law, the death of the reigning monarch is always the signal for a civil war among the surviving branches of his family, and the safety of each depends upon the extinction of the rest. Aureng-zebe's severity to his brothers, therefore, was what the security of his person, and the tranquillity of the empire demanded, and can be viewed in no other light, than as a measure of self-defence,—a measure dictated by the urgency of the times, which his predecessors had taught him, and which succeeding monarchs have been compelled to imitate. His persecution of the helpless Hindoos, however it may call for our reprehension, must be attributed to the religion which he professed, and to the dictates of that prophet which he obeyed. But his hypocritical and perfidious treatment of the unsuspecting Morad, we can neither justify nor palliate. Though in Aureng-zebe we may discover much to blame, we find more to admire. If his obedience to the customs of his country have lowered him in our esteem, his abilities as a warrior and a statesman, claim our admiration, and we cannot refuse our praise to his strict observance of religious duties, to his mild and equitable distribution of justice, to the abstemious severity of his life; to that nobleness of mind, which made him disdain not to labour for his subsistence with his own hands; and to that benevolence and humanity of disposition, which led him to declare "that the food was bitter which was drawn from the sweat of his subjects." He never did an act of injustice till he aspired to the throne; and the moderation and equity of his government make us regret that he did not obtain it without a crime. His name will ever be revered in Hindostan, of which empire he may be said to be the real founder and legislator. See *Mod. Un. Hist.* vol. vi. p. 386—455. AURIGA, or the WAGGONER, the name of one of the constellations in the northern hemisphere, containing 66 stars in the Britannic catalogue. (*w*)

AURORA BOREALIS, an extraordinary luminous appearance or meteor, shewing itself in the night-time, in northern latitudes, whence it has got its name of *northern lights*, or *northern dawn*. It is also known among the vulgar by the name of *streamers*, or *merry dancers*.

The aurora borealis may with propriety be distinguished into two kinds, the *tranquil*, and the *varying*. The tranquil shines with a mild and steady light, very much resembling the clearness of twilight; and preserves, for a considerable time, the form in which it first appears, with little or no variation. Different names have been given by the ancient philosophers to this kind of aurora, according to the forms which it assumes. They are thus enumerated by Muschenbroek: *Irabs*, or the *beam*, an oblong luminous tract, parallel to the horizon. *Sagitta*, the *arrow*, the same form with the beam, but terminating in a cusp. *Faces*, the *torch*, which has various positions in the heavens, but always one extremity larger than the other. *Capra Saltans*, the *dancing goat*, a luminous appearance agitated by

the wind, so as successively to appear and disappear. *Bothynoë*, the *cave*, a luminous cloud, having the appearance of a recess or hollow in the heavens, surrounded by a *corona*. *Pithic*, the *tun*, an aurora resembling a large luminous cask. These names, it is easy to perceive, are somewhat fanciful, and do not serve greatly to illustrate the nature of this singular meteor.

The *varying* aurora is still more remarkable in its appearance, and occasionally exhibits the most brilliant and rapidly diversified forms. It has been minutely described by Muschenbroek, who paid great attention to its peculiarities; and from whose description we select the following particulars. In that region of the air which is directly towards the north, or which stretches from the north towards the east or west, there appears at first a cloud in the horizon, which rarely rises to the height of 40 degrees. This cloud is sometimes contiguous to the horizon, sometimes detached from it; in which last case the intermediate sky appears of a bright blue colour. The cloud occupies a portion of the heavens extending in length from 5 to 100 degrees, and sometimes still farther. It is generally white and shining, but sometimes black and thick. Its upper edge is parallel to the horizon, bordered by a long train of light which rises higher in some places than in others. It appears also bent in the form of a bow, or like the segment of a sphere which has its centre considerably beneath the horizon; and sometimes a large white or luminous band is visible skirting the superior edge of the black cloud. The dark part of the cloud becomes white and luminous when the aurora has shone for some time, and after it has sent forth several bright and fiery rays. Then, from the superior edge of the cloud, there issue rays in the form of jets, which are sometimes many, sometimes few in number, sometimes close together, sometimes removed several degrees asunder. These jets diffuse a very brilliant light, as if a luminous or fiery liquor were driven with impetuosity from a syringe. The jet increases in brightness, and has less bulk at the place where it issues from the cloud; while it dilates itself and grows dimmer as it goes farther and farther off. Then there arises from a large opening in the cloud, a luminous train or column, of which the motion is at first gentle and uniform, and which increases in size as it advances. The dimensions and duration of these columns, however, vary considerably. Their light is sometimes white, sometimes reddish, or even blood colour; and, as they advance, their colours change, till they form a kind of arch in the heavens. When several of these columns, which have issued from different places, encounter each other in the zenith, they intermingle with each other, and form at their junction a small thick cloud, which seems as it were to kindle, and sends forth a light considerably more brilliant than that of any of the separate columns. This light changes to green, blue, and purple; and quitting its original situation, it directs itself towards the south, under the form of a small bright cloud. When no more columns are seen to issue, the cloud assumes the appearance of the morning dawn, and insensibly dissipates itself.—Musch. *Instit. Phys.* c. 41.

The duration of the aurora is very various. Sometimes it is formed and disappears in the course of a few minutes. At other times, it lasts during the whole night, or even for two or three days together; and Muschenbroek observed one in 1734, that lasted ten days and nights successively; and another in 1735, that

lasted from the 22d to the 31st of March. The lucid columns are so transparent, that stars of the first and second magnitude are easily seen through them; these also frequently shine through the white border of the horizontal cloud, and sometimes, though rarely, through the opaque cloud itself. But many parts of the luminous substance are so thin, that the smallest stars which are visible to the naked eye may be distinguished through them.

In high northern latitudes, as those of Sweden, Lapland, and Siberia, the auroræ boreales are singularly resplendent, and even terrific. They frequently occupy the whole of the heavens; and, according to the testimony of Maupertuis, Middleton, Kraft, and others, eclipse the splendour of the stars, planets, and moon, and sometimes even of the sun himself. In the north-eastern districts of Siberia, according to the description of Gmelin, cited and translated by Dr Blagden, (*Phil. Trans.* vol. lxxiv. p. 228.) the aurora is observed to "begin with single bright pillars, rising in the north, and almost at the same time in the north-east, which, gradually increasing, comprehend a large space of the heavens, rush about from place to place with incredible velocity, and finally almost cover the whole sky up to the zenith, and produce an appearance as if a vast tent was expanded in the heavens, glittering with gold, rubies, and sapphire. A more beautiful spectacle cannot be painted; but whoever should see such a northern light for the first time, could not behold it without terror. For, however fine the illumination may be, it is attended, as I have learned from the relation of many persons, with such a hissing, cracking, and rushing noise through the air, as if the largest fire-works were playing off. To describe what they then hear, they make use of the expression *sholochi chodjat*, that is, the raging host is passing. The hunters who pursue the white and blue foxes in the confines of the Icy sea, are often overtaken in their course by these northern lights. Their dogs are then so much frightened that they will not move, but lie obstinately on the ground till the noise has passed. Commonly, clear and calm weather follows this kind of northern lights. I have heard this account not from one person only, but confirmed by the uniform testimony of many who have spent part of several years in these very northern regions, and inhabited different countries from the Yenisei to the Lena; so that no doubt of its truth can remain. This seems, indeed, to be the real birth-place of the aurora borealis."

Maupertuis describes a very remarkable aurora which he saw at Osver-Zornea, on the 18th December, 1735, and which he says excited his admiration, notwithstanding the many extraordinary appearances of this kind which he had been accustomed to in the Arctic regions. An extensive region of the heavens towards the south appeared tinged of so lively a red, that the whole constellation Orion seemed as if dyed in blood. This light was for some time fixed, but soon became moveable; and after having successively assumed all the tints of violet and blue, it formed a dome, of which the summit nearly approached the zenith in the south-west. Its splendour was so great, as to be in no degree affected by the strong light of the moon. Maupertuis adds, that he observed only two of these red northern lights in Lapland, which are of very rare occurrence in that country, although the aurora there assumes a great variety of tints; hence they are considered by the natives

as of portentous omen, and as the forerunners of some great calamity.

This account of the noises attending the aurora borealis has been corroborated by other testimonies. They have been heard at Hudson's Bay, and in Sweden; and Muschenbroek mentions, that the Greenland whale fishers assured him they had frequently heard the noise of the aurora borealis; but adds, that no person in Holland had ever experienced this phenomenon. Mr Cavallo, however, declares, that he has repeatedly heard a crackling sound proceeding from the aurora borealis. (*Elem. of Nat. and Exper. Phil.* vol. iii. p. 449.) And Mr Nairne mentions, that, being in Northampton at the time when the northern lights were remarkably bright, he is confident he perceived a hissing or whizzing sound. Mr Belknap, also, of Dover, in New Hampshire, North America, testifies to the same fact. *Amer. Trans.* vol. ii. p. 196.

The aurora is by no means confined to the northern hemisphere. In the high southern latitudes, it was long ago observed, that there is a similar phenomenon. (*See Phil. Trans.* No. 461. and vol. liv. No. 53.) And, if the existence of the aurora australis was before in some measure doubtful, it has been completely ascertained by the second voyage round the world performed by Captain Cook. "On February 17, 1773," says Mr Forster, who accompanied Cooke in the capacity of naturalist, "in south lat. 58°, a beautiful phenomenon was observed during the preceding night, which appeared again this and several following nights. It consisted of long columns of a clear white light, shooting up from the horizon to the eastward, almost to the zenith, and gradually spreading over the whole southern part of the sky. These columns were sometimes bent sideways at their upper extremities; and though in most respects similar to the northern lights of our hemisphere, yet differed from them in being always of a whitish colour; whereas ours assume various tints, especially those of a fiery and purple hue. The sky was generally clear when they appeared, and the air sharp and cold, the thermometer standing at the freezing point."

Various attempts have been made to determine the height of the aurora borealis, but with very little success. Bergman, from a mean of thirty computations, makes the height of this phenomenon to be 72 Swedish, or about 458 English miles. Father Boscovich calculated the height of an aurora borealis, observed on the 16th December 1737, by the Marquis of Poleni, to have been 825 miles: Mairan supposed the far greater number of auroræ to be at least 600 miles above the surface of the earth; and Euler assigned them an elevation of several thousands of miles. Dr Blagden, however, limits their height to about 100 miles, which he supposes to be the region of fire-balls; remarking that instances are upon record, in which the northern lights have been seen to join, and form luminous balls, darting about with great velocity, and even leaving a train behind them like common meteors.—*Phil. Trans.* vol. lxxiv. p. 227.

Respecting the cause of this beautiful phenomenon, a great variety of theories have been proposed. When the science of meteorology was in an imperfect state, it was natural to ascribe the aurora borealis to fiery or sulphureous vapours exhaled from the bowels of the earth, and rising into the region of the air; and Muschenbroek is at pains to point out certain chemical mix-

tures which send forth a phosphorescent steam or vapour, in many respects resembling the northern lights. Dr Halley, also, at first proposed a similar theory: conceiving that the watery vapours which are rarefied and sublimed by subterraneous fire, might carry along with them sulphureous vapours sufficient to produce this luminous appearance in the atmosphere. He soon, however, abandoned this hypothesis, which is evidently very insufficient to account for the phenomena; and supposed that the aurora borealis might be occasioned by the circulation of the magnetic effluvia of the earth from one pole to the other. It was an hypothesis of this philosopher, that the earth is a hollow sphere, inclosing within it another sphere, which has a strong magnetic virtue, to two poles which are nearly but not perfectly coincident with the poles of the world. The inner sphere he supposed to have a slow revolution on its axis, independent of the diurnal rotation of the earth, by which he accounted for the variation of the magnetic needle; and he supposed that there is a constant circulation of the magnetic fluid from the north to the south pole through the air; which is counterbalanced by a circulation from the south to the north pole, through the pores of the earth. The magnetic effluvia, darting upwards from the north pole into the higher regions of the atmosphere, acquire such an impetus as to render the circumambient ether luminous; and give rise to all the phenomena of the aurora borealis. It has never, however, been shewn, that magnetic effluvia can in any case produce light; and according to this theory, the aurora ought at the south pole to direct itself towards the earth; whereas Mr Forster found it moving rapidly towards the zenith, just as it does in the northern hemisphere.

The celebrated academicien M. de Mairan, in 1731, published a treatise upon the aurora borealis, in which he ascribes this phenomenon to the impulse of the zodiacal light upon the atmosphere of the earth. The zodiacal light is a luminous train, which is visible at certain seasons, a little before sunrise, or after sun-set, in the shape of a pyramid or lens, stretching along the zodiac. It was first discovered by Cassini, who conceived it to be the atmosphere of the sun, formed by a very rare fluid, luminous in itself, or illuminated by the sun's rays, but not equally throughout; being much more luminous, and more extended around the equator of the sun; in which direction it forms a very oblate spheroid, or rather lens, of which the transverse section coincides with the plane of the sun's equator. See *ASTRONOMY INDEX*.

"It is proved by observation," says M. de Mairan, "that this solar atmosphere extends sometimes as far as the earth's orbit, and even farther. When, therefore, it is at its greatest extent, the earth will be immersed in it; in which case a quantity of the luminous matter, influenced by gravitation, falls upon the earth's atmosphere, and descends more or less within it according to its weight; each luminous particle descending till it meet with a stratum of air, with which it will be in equilibrium. But as the equatorial regions have a greater centrifugal force than the polar, on account of their greater velocity during the earth's diurnal rotation, the luminous particles of the zodiacal light must be driven by this centrifugal force, from the equator towards the poles; and it is then that they form those luminous arches which we call the *aurora borealis*. (See *Tract. Phys. and Hist. del. Auroræ Bor.*) Besides this express treatise, there are several papers on the subject of the aurora borealis, by M. de Mairan, in the Memoirs of the

French Academy; one in particular for the year 1733, in which he records a variety of his observations on the zodiacal light, made with a view to confirm his theory; and another for the year 1747, in which he defends his theory against the attacks of Euler, who wrote a treatise in order to refute it, and establish a new doctrine of his own.

Euler justly observes, that the theory of M. de Mairan is not only exposed to the objection of resting upon hypothesis, rather than upon observed facts, but that it is inconsistent with the direction in which the aurora is constantly observed to move; which is not from the equator towards the poles, but conversely from the poles towards the equator. He himself ascribes the aurora, not to the zodiacal light, but to the luminous particles of our own atmosphere, driven beyond its limits by the light of the sun, and sometimes ascending to the height of several thousand miles. This, it must be owned, is no very brilliant specimen of the philosophical acumen of this celebrated mathematician. See *Mem. Acad. Berlin*, 1746, p. 117.

As soon as the phenomena of electricity, and the laws by which they are governed, were tolerably understood, philosophers very naturally had recourse to this agent, as affording a satisfactory explanation of the aurora borealis. The brilliancy of its light, the rapidity of its motions, and the instantaneous changes of form which it underwent, all seemed plainly to point to this powerful element as the cause of these striking phenomena. Mr Hawkesbee, too, had very early shewn, that the electrical fluid assumes an appearance resembling the aurora borealis, when it passes through a vacuum or highly rarefied atmosphere. If a glass tube, resembling a Florence flask in size and shape, be exhausted of air by means of a stop-cock and syringe fixed to its mouth, and be then excited by friction, it will appear filled with a pale light, resembling the aurora borealis, which will go and come at intervals, sending forth brilliant flashes, exactly as this meteor does in the heavens. If either end of the flask be presented to the conductor of an electrical machine, the other being held in the hand, a constant stream of pale light will be transmitted through it, proceeding from the conductor. Mr Canton, also, contrived to exhibit an imitation of the aurora borealis, by means of electricity transmitted through the Torricellian vacuum, formed in a glass tube about three feet long, and hermetically sealed. When one end of the tube is held in the hand, and the other applied to the conductor of an electrical machine, the whole tube is illuminated from end to end, and will continue luminous for a considerable time after it has been removed from the conductor. If, after this, it be drawn through the hand either way, the light will be uncommonly intense, extending without the least interruption, from one hand to the other, even throughout its whole length. By this operation, however, a great part of the electricity is discharged; nevertheless the tube will flash at intervals, if held at one extremity and kept quite still; but if it be grasped by the other hand at the same time in a different place, strong flashes of light will hardly ever fail to dart from one end to the other, which will continue twenty-four hours and longer, without any fresh excitation. An arched double barometer, of a considerable height, exhibits these phenomena in a still more striking manner.

Thus we find that a small quantity of electricity, excited in a highly rarefied atmosphere, or in a medium

approaching to a perfect vacuum, will exhibit luminous appearances entirely resembling the aurora borealis, for a very considerable space of time. With respect to the variations of colour which we find in the aurora borealis, these seem fairly ascribable to the different degrees of rarefaction of the air: for the same electricity which appears white in a very rare medium, becomes blue, purple, or red, in a medium of increased density; as is fully evinced by the following experiment. Let an electrical machine and an air pump be so disposed, that while the machine is worked, a succession of strong sparks shall be communicated from the prime conductor to a metallic knob attached to the top of the receiver of the air pump. Let now the exhaustion of the receiver proceed, and we shall soon perceive the electricity forcing itself through the air within it, in a visible stream. At first this stream is of a deep purple colour; but, as the exhaustion advances, it changes to blue; and at length to an intense white, with which the whole receiver becomes completely filled.

This experiment would appear to establish the identity of the aurora borealis with electric light; and it may be mentioned as collateral proofs of this identity, that the atmosphere is found, by the electrometer, to abound with electricity when the aurora shines forth; that the aurora, when strong, is accompanied with the whizzing or crackling sound of electricity; and that the magnetic needle is evidently disturbed by the aurora, as well as by the action of an electrical machine, or by the natural electricity of a thunder storm.

But how, it may be asked, are all the subordinate phenomena of the aurora borealis to be accounted for by the action of electricity; and why is it circumscribed to the polar latitudes, and the more elevated regions of the atmosphere? Mr Canton conjectured, that the aurora borealis is occasioned by the flashing of the electric fire from positive towards negative clouds, at a great distance, through the upper part of the atmosphere where the resistance is least. But were this all, the aurora ought to be as abundant in the tropical regions as in the polar; and it ought to dart in all directions, instead of uniformly pointing towards the zenith. Signior Beccaria, who paid very great attention to atmospherical electricity, supposed that there is a constant and regular circulation of the electric fluid from the north pole to the south; and he thinks that the aurora borealis may be this electric matter performing its circulation, in such a state of the atmosphere, as renders it visible on approaching nearer to the earth than usual. This supposition, however, is altogether inconsistent with Mr Forster's observations, already mentioned; according to which the columns of the aurora shot upwards from the horizon towards the zenith, as well in the southern as in the northern hemisphere.

The course of the aurora, therefore, is uniformly from the poles towards the equator; and supposing it to consist in a stream of electric light, the following reasons may be assigned for its constantly preserving this course. Extreme cold renders almost all bodies electric, or disposed to accumulate electricity; while heat and moisture occasion a conducting power. Air, when dry and cold is powerfully electric; and hence the beautiful phenomena of the aurora are confined to the polar regions, and appear by night and not by day, and in winter rather than in summer. The inferior part of the atmosphere, between the tropics, is violently heated during the day time, by the reflection of the sun's rays from

the earth, while the superior parts retain their original cold. It is also impregnated with moisture exhaled by the powerful heat which then acts upon the earth. It is therefore in the conducting state, and readily communicates the electricity of the superior regions to the clouds which float in it, or to the body of the earth. Hence the awful electrical phenomena of the tropical regions, exhibited in thunder and lightning, water spouts, whirlwinds, and the most tremendous tempests. The electrical fluid is thus conveyed in great quantities from the upper parts of the atmosphere, between the tropics, to the lower stratum, and thence to the earth; and the inferior and warm atmosphere, having once exhausted itself must necessarily be recruited from the upper and colder region.

These principles are greatly illustrated and confirmed by what happened to the French mathematicians, when stationed on the top of one of the Andes. They found themselves frequently involved in clouds, which, sinking down into the warmer air, appeared there to be highly electrified, and discharged themselves in violent tempests of thunder and lightning; while in the mean time, on the top of the mountain, they enjoyed a calm and serene sky.

Thus, as the hot air of the torrid zone is continually bringing down vast quantities of electric matter from the cold air that lies directly above it, it follows, that the upper parts of the tropical atmosphere will continually require a supply from the northern and southern regions. Hence the constant electric current in the upper parts of the atmosphere, from the poles towards the equator; which in the colder regions, where the air is sufficiently rarefied, assumes the form of the aurora borealis and australis; and hence, this meteor is more frequent in winter than in summer; because, at that time, the electric power of the inferior atmosphere is greater, on account of the greater degree of cold; and it is in the night and not in the day time that it displays itself, because, during the day, the heat of the sun is sufficient to impart to every portion of the atmosphere a conducting power. With respect to the perpendicular direction which the streams of the aurora appear to assume, it need not be considered as a material difficulty; since, as Dr Halley has observed, they must dart from the pole in arches of circles of very great diameter, and consequently appear erect to those who view them from the earth's surface. The upper regions of the atmosphere, on account of their superior rarity, afford them the readiest passage, and hence they assume the perpendicular direction rather than any other.

Dr Franklin has given a different form to the electrical theory of the aurora borealis, supposing that the electricity which is concerned in this phenomenon passes into the polar regions, from the immense quantities of vapour raised into the atmosphere between the tropics; and that the light appears first, where it is first in motion, that is, in the most northern part; so that the appearance proceeds southward, though the fluid really moves northward. (*Exper. and Observ.* 1769, p. 49.) Mr Kirwan (*Irish Trans.* 1788) supposes, that the light of the aurora borealis and australis is occasioned by the combustion of inflammable air, kindled by electricity. He is of opinion, that a great quantity of this gas, which is formed by a variety of natural processes, occupies the higher regions of the atmosphere, on account of its extreme levity; and is the cause of the auroræ, which are the highest of all meteors. But as

far as we may trust to the observations of aéronauts, there is no evidence whatever, that inflammable air is more abundant in the upper, than in the lower regions of the atmosphere; and were it the cause of the aurora, this meteor should abound in the tropical as well as polar regions.

With respect to the observation of Dr Kirwan, that the barometer commonly falls after an aurora, this is no more than what takes place also after a thunder storm; and its being followed by high winds from the south is as explicable on the electrical, as on the inflammable gas theory. Mr Winn, in the 73d volume of the *Phil. Trans.* makes the same remark, and says, that in 23 instances, without fail, a strong gale from the south or south-west followed the appearance of an aurora. If the aurora were bright, he says the gale came on within 24 hours, but was of no long continuance; if the light was faint and dull, the gale was less violent, and longer in coming on; but longer also in duration. His observations were made in the English channel, where such winds are very dangerous, and by attending to the aurora, he says, that he often escaped shipwreck while others suffered. As we have supposed a stream of electricity to be constantly passing through the mass of the earth, from the equator towards the poles, it is evident, that a wind may be occasioned by this electricity finding a ready vent at some promontory or head-land. And should we suppose one of those vents situated on the coast of France, or in the Bay of Biscay, the electric matter that has been received at the equator, during an aurora borealis, will be discharged there for some time after; and consequently will occasion a wind from that quarter, which will be south-west in the English channel. According, however, to the different situations of these electrical vents, winds may blow in very different directions in different quarters of the world.

The most unaccountable of all the circumstances respecting the aurora borealis, is, that it is not much more than a century since this phenomenon has been observed to occur with any degree of frequency in our latitudes. We find indeed a few remarkable atmospheric phenomena recorded by the ancients, which may be reckoned examples of this meteor, viz. in Aristotle's *Meteor.* l. i. c. 4, 5; and Senec. *Quest. Nat.* l. 1. c. 15. Pliny also (l. ii. c. 27.) speaks of a bloody appearance of the heavens, which seemed like a fire descending upon the earth, seen in the third year of the 107th Olympiad; and of a light seen in the night-time equal to the brightness of day, in the consulship of Cæcilius and Papyrius (l. ii. c. 33.) both which may be referred to the aurora borealis. But, with such trifling exceptions as these, the whole of antiquity is absolutely silent on this subject. Dr Halley informs us, that he had begun to despair of witnessing this beautiful phenomenon, when the remarkable aurora of 1716 made its appearance. This philosopher has given us a historical detail of the several observations of this meteor, in which he says, that the first account of it upon record, in an English work, is in a book entitled, *A Description of Meteors*, by W. F. D. D., reprinted at London, in 1654, which speaks of "burning spears" being seen Jan. 30, 1560. The next appearance of a like kind is recorded by Stow, and occurred on October 7, 1564. In 1574, according to Stow and Cambden, an aurora was seen for two successive nights, viz. the 14th and 15th of November. The same phenomenon was twice seen in Brabant in 1575, viz. on the 13th of February and the 28th of September; and the circumstances accompanying it

were described by Cornelius Gemma, who compares them to spears, torified cities, and armies lighting in the air. In 1580 and 1581 this phenomenon was repeatedly observed at Bakhang, in the county of Wirtemberg, in Germany. But from this time to 1621, we have no such phenomenon on record, when it was seen all over France on September 2, and is particularly described by Gassendi in his *Physics*, under the title of *Aurora Borealis*. In November 1623, another was seen all over Germany, and is particularly described by Kepler. Since that time, for more than eighty years, we have no account of any such phenomenon being observed; but in 1707, Mr Neve observed one of short continuance in Ireland; and in the same year, a similar appearance was seen by Romer at Copenhagen; while, during an interval of eighteen months, in the years 1707 and 1708, this sort of light had been seen no less than five times. The aurora of 1716, which Dr Halley particularly describes, was remarkably brilliant. It was also visible over a prodigious tract of country; being seen from the west of Ireland to the confines of Russia, and the east of Poland; extending near 30° of longitude, and from about the 50th degree of north latitude, over almost all the north of Europe; and in all places exhibiting, at the same time, appearances similar to those observed in London.

It appears, then, to be certainly established, that the aurora was of very rare occurrence in our latitudes till about a century ago; for it cannot be supposed that so beautiful and striking a phenomenon would have passed unnoticed, and unrecorded, during the two preceding centuries, while men of science, and particularly astronomers, were so busily employed in examining every remarkable appearance of the heavens; or that the philosophers of Greece and Rome would have remained silent concerning so beautiful a meteor, had it been in any degree familiarly known to them. It is in vain to account for their silence by saying, that they inhabited latitudes which are scarcely ever visited by this appearance; for the Romans not only visited, but long resided in the north of Germany, and in Britain, where the aurora is now frequently seen in great splendour.

The following ingenious theory has been proposed, with a view to resolve this difficulty. There is a very remarkable analogy between the phenomena of electricity and those of magnetism, and apparently, an intimate dependence of the one upon the other. There are two species of electricity, a positive and a negative, and two species of magnetic polarity, a north and a south. A body positively electrified repels another body positively electrified, and attracts one that is electrified negatively; while the north pole of one magnet repels the north pole, and attracts the south pole of another. The electric shock will deprive a magnetic needle of its power, or communicate it to it again, according to the direction in which it is laid; and, during a thunder storm, the magnetic needle is observed to be powerfully agitated. Thus the intimate connection between electricity and magnetism seems to be satisfactorily established. Again, that imaginary line, or circle, which traverses the earth irregularly from the north towards the south, and is called the *line of no variation*, because the magnetic needle, when placed upon it, points truly to the poles, is observed to have a gradual, and pretty regular, revolution around the earth, performed in about 1000 years: so that, when 1000 years have elapsed, the line of no variation will have reached the same situation which it occupied at the beginning of that period.

This line seems to have a sort of controul over the corruscations of the aurora, which are observed to follow its direction in the heavens, and, as it were, to be attracted towards it, and regulated by its influence in their course.

But it appears, by calculation, that during the scientific age of Rome, the only period at which accurate observations of the phenomena of the heavens could be made and recorded, the line of no variation run across the continent of Europe; and consequently the aurora borealis, or stream of electrical matter that passes from the north pole towards the equator, would find a ready vent from the earth into the sky, through the mountains, and other pointed bodies which are so plentifully scattered over the land. By thus flowing constantly, and so greatly subdivided, it could not give rise to any striking atmospheric phenomena. At present, the direction of this line is through the Atlantic ocean; and of consequence, the electricity of the polar regions is not imperceptibly transmitted to the atmosphere, but proceeds in such masses, and at such irregular intervals, as to exhibit itself in the beautiful phenomena of the northern lights. A thousand years ago the line of no variation, no doubt, occupied the same situation as it does at present; and the aurora then shone forth in all its splendour; but, at that period, the nations of Europe were sunk in ignorance and barbarism; and whatever phenomena the heavens presented were lost to posterity, from the rudeness and want of knowledge of the people of that age. Thus, if this theory be true, when the line of no variation shall again pass over the land, the aurora borealis will become invisible for a time; and when this line reverts to its present situation over the ocean, the aurora will once more shine forth with its wonted lustre. (*m*)

A new theory of the aurora borealis has lately been proposed by M. Monge. He imagines that this phenomenon is merely clouds illuminated by the sun's light, which falls upon them after numerous reflections from other clouds placed at different distances in the heavens. If we suppose that clouds placed in the atmosphere are enlightened by the direct rays of the sun, and reflect the light which they receive to other clouds, situated in a part of the heavens deprived of the direct light of the sun, and if we suppose this light to be necessarily reflected to other clouds, we shall have some idea of the possibility of a mass of thin clouds being illuminated by the sun, when this luminary is considerably depressed below the horizon of the spectator. The intensity of these radiations will depend on the dispersion and absorption of the light in its successive reflections, and it will be more distinctly perceived when the rest of the atmosphere is involved in darkness. Upon this hypothesis, Monge has explained why the phenomenon is perceived near the poles, and why it is most frequently seen between the vernal and autumnal equinoxes. See *Leçons de Physique*, par Pujoulz, 1805. p. 237.

Another theory of this singular phenomenon has been recently proposed by M. Libes. It is founded on the following principles. 1. If the electric spark is passed through a mixture of azotic and oxygen gas, nitric acid, nitrous acid, or nitrous gas, will be produced, according to the proportion which exists between the azot and oxygen. 2. The nitric acid exposed to the sun, becomes more coloured and volatile. If a receiver is placed over a vessel containing this acid, exposed to the rays of the sun, the acid will in a few minutes become

coloured, and the receiver will be filled with red and volatile vapours, which continue for a long time, and exhibit a brilliancy resembling the aurora borealis. 3. In the flasks which contain the nitrous acid, there is always above the acid, a red and volatile vapour, which is never condensed. 4. Nitrous gas, in contact with atmospheric air, exhales red vapours, which fly away in the atmosphere. 5. The hydrogen gas which disengages itself from the surface of the earth, rises to a height in the atmosphere corresponding with its specific gravity. 6. The heat of the sun is extremely feeble in the solar regions. From these principles, M. Libes concludes that there is very little hydrogen produced in the polar regions, and that therefore there is almost none of this substance in the higher regions of the atmosphere. The electric fluid, therefore, passing through a mixture of azot and oxygen, will produce, nitric acid, nitrous acid, or nitrous gas, and these substances, acted upon by the solar rays, will exhibit those red and volatile vapours, which form the aurora borealis. A more complete account of this ingenious theory may be found in the *Traite de Physique*, par Libes, or in the *Dictionnaire de Physique*, of the same author; and in Rozier's *Journal*, June 1790, Feb. 1791, and vol. xxxviii. p. 191.

The latest theory which has been employed to account for the aurora borealis is that of our ingenious countryman Mr Dalton, who considers it as a magnetic phenomenon, whose beams are governed by the magnetism of the earth. He supposes that these beams are cylindrical portions of a magnetic fluid, which are actually parallel to the dipping needle, and therefore appear to converge to the magnetic pole; and that the light is produced by the transmission of electricity, which disturbs their magnetic properties. Mr Dalton observes, that the luminous arches are always perpendicular to the magnetic meridian; and that, from the permanency of their form, they afford an opportunity of determining the height of the meteors. From an observation on a base of 22 miles, he found its altitude to be about 150 miles. See Dalton's *Meteorological Observations and Essays*, 1793, p. 54. 153.

The Abbe Bertholon ascribes the aurora borealis to a phosphorico-electric light. A full account of this theory has been given by its author in the *Encyc. Method. art. AURORÆ*.

Much interesting information respecting the aurora borealis, will be found in the following works: Muschenb. *Instit. Phys. c. 41. Tract. Phys. et Hist. de l'Aur. (o) **AUSONIUS, DECIMUS MAGNUS**, a Latin poet, was the second son of Julius Ausonius, an eminent physician at Bourdeaux. He was born early in the fourth century; and his grandfather, a firm believer in astrology, having calculated his horoscope, flattered his family with the hope that the child was destined to rise to the most honourable elevation. His uncle, Æmiliius Magnus Arbo-rius, a professor of rhetoric at Thoulouse, took a particular charge of his education, and the pleasure of witnessing the uncommon progress which he made in the liberal arts. At the age of thirty he was appointed to the useful station of teacher of grammar, and soon after to that of teacher of rhetoric, in his native city. In this comparatively obscure situation, he conducted himself so much to the satisfaction of his employers, that his high reputation extended to Rome, and he was chosen by the Emperor Valentinian to direct the studies of Gratian, his son. He had the good fortune, or rather the address, to make himself equally acceptable to his pupil and to the emperor; both of whom loaded him with honours, as a remuneration for his valuable services. During the life of Valentinian he was appointed quæstor; he was afterwards advanced to the prætorian præfecture of Italy and Gaul; and, in 379, he was raised to the consulship, an office which the emperors generally conferred on their minions, but which, in this instance, was filled by a man, whose mental superiority enabled him to dictate to his master. The composition in which he testified his gratitude, (*Actio Gratiarum*) is commonly accounted a proof of great liveliness and vigour of mind in a man far advanced in years; but Gibbon more justly characterizes it as "a servile and insipid piece of flattery, which has survived more worthy productions." He died at a great age, towards the close of the fourth century. Theodosius had so great a respect for him, that, according to some authors, he promoted him to the patrician dignity; and it is certain, that the solicitation of this accomplished emperor induced him to publish his poetical works.

What was the religion of Ausonius has been much disputed. Vossius, and some other writers, whom Gibbon has followed, have no hesitation in pronouncing him a pagan. But Paulinus, bishop of Nola, who had been his pupil, speaks of him as a Christian. Yet, in his own writings, we can discover no internal evidence that he had adopted the true faith. In some of his verses he appears to be sceptical on the subject of a future life; and some others, written by command of Valentinian, are so indelicate and licentious as to render it questionable if their author had any sense of religion at all. See *Mem. de l'Acad. des Inscript.* tom. xv.; and Bayle, *Dict. Histor. et Crit.*

His poetical character has generally been overrated. His productions rise above mediocrity. Most of the subjects are ephemeral; and the execution bears evident marks either of negligence or affectation. His genius is undisputed; but long before his time the taste of the Romans had degenerated; and it is enough to say of Ausonius, that, in sentiment and diction, he rises

above the ordinary level of his contemporary rivals. One of the best editions of his works was published at Paris in 1769, in four volumes 12mo, with a French translation. (λ)

AUSPICES, the observations taken by the Romans, augurs from the flight of birds, and other natural appearances. The words *auspicy* and *augury* are often used indiscriminately; but the common opinion is, that the former originally signified the inspection of birds, for the purpose of divination, whereas the latter consisted in a skillful attention to their voices. The name *auspex* was applied to any person who interpreted omens; but the name *augur* was not extended to any but the members of the sacred college.

Auspices were anciently consulted on almost every occasion of importance, particularly on the election of magistrates, and at the commencement of military expeditions. The *comitia centuriata* and *curiata* could not legally meet, till he who was to preside, accompanied by an augur, had solemnly taken the auspices. Two kinds of auspices were chiefly attended to before the assemblies were held: those which were taken from the contemplation of the heavens; and those which were taken either from the *oscines* or the *ipæfetes*, birds by whose singing or flight the will of the gods was supposed to be indicated. On these occasions the augur could prevent a meeting, or he could require a delay; or, by declaring that some mistake had been committed, he could not only dissolve an assembly after it was regularly convened, but oblige a magistrate at any time to resign his office, on account of the alleged informality. In later times they were by no means so scrupulous with regard to the forms. The augurs were in the constant habit of declaring that they saw lightning on the left, and the falsehood of the assertion did not vitiate the election.

In the time of war, auspices were taken *ex acuminibus*, from the beaks of birds; and whenever a general was about to lead his army across a river, he took the *auspicia perennia*, or *perennia*. Every military enterprise was said to be accomplished by the *auspicia* of the consul or commander in chief.

The solemnities most commonly observed when the auspices were taken have been shortly described in the article **AUGURY**. See also **DIVINATION**. (λ)

AUSTERLITZ, a small town of Moravia, in the circle of Brunn, celebrated for a dreadful battle which was fought in its vicinity, on the 2d December 1805, between the French and the allied Russians and Austrians. This bloody engagement, which terminated in favour of the French arms, decided the campaign, and peace was signed at Presburg, on the 26th of the same month. The Russians, who suffered chiefly, are said to have lost 15,000 killed and wounded, and 100 pieces of artillery. This conflict has been called by the French the Battle of the Coronation, as it was fought on the anniversary of Bonaparte's coronation; and the Battle of the three Emperors, from its being attended by the emperors of the three contending powers. (j)

AUSTEL, AUSTIL, or AUSTLE, a market-town of England, in the hundred of Powder, in Cornwall. This town, which is built on the side of a hill, and stands nearly in the centre of the county, has for some time been in a flourishing state, from its being the seat of one of the stannary courts, and from the great turnpike road from London to the Land's End, which passes

through it. In the vicinity of the town are several tin mines, and also quarries of porcelain, which is sent to Liverpool, Bristol, and Staffordshire, for the use of the potteries. The inhabitants are chiefly employed in the mines, in the pilchard fishery, and in a manufactory of

coarse woollen cloths. Number of houses 663; population 3788, of whom 390 are employed in trade. See *Beauties of England and Wales*, vol. ii. p. 422.; and Powell's *History of Cornwall*. (J)

AUSTIN, SAINT. See AUGUSTINE.

AUSTRALASIA.

A vague and indistinct idea long prevailed among the more enlightened European nations, that an immense continent existed at the south pole of the world, which they denominated *Terra Australis Incognita*. This, from the capes and islands casually seen by navigators, was supposed to extend over many degrees of the polar regions; and sanguine hopes were indulged, that in future periods its shores might be visited and surveyed in safety. Later researches, however, have proved the fallacy of these expectations: they have ascertained, that if there is any continent, it can be only of a limited size, and that it is guarded on all sides by an impenetrable barrier of ice. Modern geographers have nevertheless testified an inclination to subdivide the vast expanse of southern hemisphere explored in voyages undertaken to discover the *Terra Australis*, and to call one portion of it by the new appellation of *Australasia*. We acknowledge that we entertain considerable doubts of the expediency of this improvement on geographical nomenclature, and we also hesitate in admitting the proposed division as the best that can be made; for we cannot help suspecting, that the readiness evinced to receive it, arises less from a conviction of its utility, than from that propensity to innovation in nomenclature, which is now so prevalent, and which has plunged entire sciences into absolute confusion. Although we may justly question, whether the establishment of boundaries, by lines drawn through a trackless ocean, can prove of material advantage, we agree, that the concentration of our views, by any striking limits, cannot fail to be beneficial; especially when the judgment is liable to be distracted by a great variety of objects presented without order or arrangement. Australasia, according to the proposed division, extends from 5° of north latitude to 50° south, and from 95° of east longitude to 185°; thus comprehending a surface of 5000 miles in length, by about 3180 in breadth. Geographers, however, have not yet condescended to agree on the exact limits under which it is to be included, particularly towards the north-eastern parts; and therefore, though we have assumed the same boundaries that some of the latest authors have done, yet we do not consider them as by any means completely fixed.

The name Australasia is said to have been originally proposed by M. de Brosses, a skilful geographer; who meant to comprehend under it the countries south of Asia, including New Holland, New Zealand, and New Guinea. This suggestion proceeded, in a great measure, from the belief of a southern continent towards the pole being still undiscovered; but, independent of this circumstance, his reasons bear much weight when considered in another point of view: "In the immense extent of regions about to be explored," he observes, "how various are the countries, the climates, the manners, and races of men. Were not some fixed points assumed from place to place, our judgment would be bewildered. Divisions, relative to the progress of our knowledge, and also preserving due regard to physical

circumstances, should be laid down. Four great portions of land, Europe, Asia, Africa, and America, constitute the world: and there are three wide extents of ocean, the Indian, or Ethiopic; the North, or Atlantic; and the South, or Pacific. The unexplored southern regions may be divided into three portions, corresponding to them; each division being to the southward of one of the three portions of land. That to the south of Asia, in the Indian Ocean, I shall, on this account, call Australasia." A fifth part of the world would thus be constituted, bearing a reasonable proportion in size to the others in point of the land it contained. De Brosses had also proposed another subdivision of the southern hemisphere, which would have further contributed to preserve equality.

Australasia, according to the limits which we now ascribe to it, is larger than the whole of Europe. The principal countries it includes are,—1. The immense island, if it may be called such, of New Holland, nearly 2000 miles in breadth, and almost 1700 in length; 2. Van Diemen's Land; 3. Papua, or New Guinea; 4. New Britain, and New Ireland; 5. The Arcades, or Solomon's Islands; 6. New Caledonia; 7. New Zealand. Besides these, which present the most prominent terrene objects in Australasian geography, there are hundreds, probably thousands, of smaller and detached islands, many of which have never been accurately surveyed, and it is highly probable that some are still unknown. Compared with all the other land in Australasia, New Holland may safely be calculated of tenfold greater size; and it is likely that three-fourths of the whole regions consist of water. Nevertheless, we may deem the views of the older geographers as in some part fulfilled, by including such extensive tracts of land in Australasia.

Here we shall take a brief retrospect of the progress of discovery of the various countries comprised under this general denomination; treating, in the first place, of what was known previous to the commencement of the eighteenth century; and then we shall draw some general conclusions concerning the products of Australasia, and the manners of the natives. The different properties of the countries, and their inhabitants, will be resumed, in greater detail, under other articles of our work.

The extent and importance of New Holland justly claim priority of consideration, though we possess no evidence in favour of its being earlier known than the rest; which leads us to remark, that more of the Australasian countries than one having been recognized during the same voyage, we are precluded from observing that strict chronological order which is so desirable in historical inquiries. The discovery of New Holland has commonly been ascribed to Dutch navigators of the seventeenth century. M. de Brosses refers it to an earlier period, judging it probable that it was discovered by *Paulmyer de Gonneville* in 1508, who sailed from Honfleur in June of that year. Off the Cape

of Good Hope he was assailed by a furious storm, in which he lost his reckoning, and was driven into an unknown sea. As he saw the birds flying from the south, he sailed towards that quarter, and reached an extensive country, which he called Southern India. There he spent six months, refitting his vessel, and lived on friendly terms with the inhabitants. On comparing the meagre accounts which he gives of their manners, and those of any of the Australasians according to the earliest narratives, we conclude that they are of a different race, and had made much greater advancement in civilization. A set of maps, constructed in the year 1542, or perhaps earlier, has been lately found, wherein some part of New Holland is supposed to be laid down. But we are so little acquainted with these maps, that we cannot venture to maintain an opinion concerning them; at the same time we ought to remark, that repeated instances occur, as will be seen in the course of this article, where later navigators claim the merit of discoveries which belong, so far as we can judge, to those who have lived centuries before them.

Early in the seventeenth century, the Spanish navigator Quivos is conjectured to have seen the north, or north-east coast of New Holland. In the year 1606 he traversed the Australasian seas, with a fleet under his command; and, on attending to his tract, the fact is far from improbable. But the Dutch were the first who became acquainted with any extent of coast, or the nature of the country. Soon after Quivos left that region, they made several successive voyages to it, and gave those names to the north and western parts of New Holland which are retained to the present day. Doubts were started, whether any of them effected a landing previous to Pelsart, in 1629. These have been removed by the French finding a tin platter on an island called Dirk Hartigh's Island, close to New Holland, in 1801, which bore the following inscription, rudely graven: "1616, On the 25th of October, the ship *Endragt* of Amsterdam arrived here; first merchant Gilles Miebaïs Van Luck; Captain Dirk Hartighs of Amsterdam. She sailed on the 27th of the same month. Bantum supercargo; Jansins chief pilot; Pieter Ecoores Van Bue year 1616." Hartighs's vessel was on a voyage to India at the time of touching on the coast, which in the Dutch charts is called *Landt D'Eendragt*. As the inscription ascertains the name of his vessel, what is called the *Concord's Coast* probably received that appellation from some other vessel in company, or from some future navigator, contrary to general belief. In 1618, another Dutchman, *Zeechen*, ran along the north coast of New Holland, which was then, or soon afterwards, called *Arnhem*, or *Van Diemen's Land*; and several of his countrymen, in the years immediately subsequent, extended the knowledge of this great island. *Edel's Land* was called after a navigator of that name in 1619; *Leuwin's Land* was discovered in 1622; and *Peter de Nuytz*, in a vessel named the *Golden Horse*, fixed the position of different points in 1627, which the latest voyagers acknowledge to be uncommonly correct. *William de Wit*, *Vianen*, and *Carpenier*, a Dutch general, were on the south and west coasts in 1627 and 1628. In the subsequent year, *Francis Pelsart*, commanding a ship, which was separated in a storm from ten others, approached the west

coast of Holland. There he met a storm, and he was cast away on *Frederic Houtman's Shoals*, which the French affirm are about eight leagues from the main land. The crew and passengers were saved by the boats, and carried to a small island, about three leagues distant, which we apprehend to be the island *Turtle Dove*; but finding no water there, *Pelsart* examined a number of others, where he got some in the cavities of the rocks, though unfit for use. A few days afterwards, having put a deck on his boat, which was unable to stand the sea, and having ascertained the position of the islands to be $28^{\circ} 13'$ south, he stood on for the land. Stormy weather and a rocky shore prevented him from landing from the 9th of June to the 15th. In $22^{\circ} 17'$ south latitude, he saw the savages at a distance, who fled whenever he and his people approached; and he found the remains of their provisions beside fires on the beach. Circumstances, which it is unnecessary now to recapitulate, induced *Pelsart* to run for the coast of *Java*, which he saw on the 27th. Having obtained assistance from *Batavia*, he returned to the island in September, and brought away the survivors of the shipwrecked persons. Most of those who had escaped the shipwreck had been cruelly murdered by means of the supercargo. The chief discoveries which the Dutch made in Australasia during the seventeenth century, were those by *Abel Jansan Tasman*, in 1642; and the large island, or continent, of which we speak, received the name of *New Holland* in 1644. *Tasman* sailed from *Batavia* in August 1612, with two vessels under his command, the *Heemskirk* and *Zeehaan*. On the 24th of November, when in latitude $42^{\circ} 23'$ south, and east longitude $163^{\circ} 50'$, he saw land, bearing north-east, ten miles distant, which he called *Van Diemen's Land*. Running along the coast, he anchored in a bay, which he called *Frederic Henry's Bay*, in latitude $43^{\circ} 10'$, and longitude $167^{\circ} 55'$. He saw no people, but lofty trees, with deep notches, which the natives had cut to assist them in climbing. This land, discovered by *Tasman*, was long esteemed the southern part of *New Holland*; but later discoveries have proved it to be quite a different country.

The Dutch were, therefore, the first, so far as we can at present ascertain, who made any observations on this part of Australasia, which, indeed, their establishments in India, and frequent voyages thither, enabled them the more readily to do. Accordingly we find, that it was in such voyages commonly that they became acquainted with the coast. In the year 1696, *Vlaming* sailed from the *Texel* in quest of a Dutch East Indiaman, supposed to have been lost somewhere on the coast of *New Holland*, during a voyage from the *Cape of Good Hope* to *Batavia*. In December of the same year he made the coast in $31^{\circ} 58'$ south latitude, and $130^{\circ} 13'$ east longitude. He landed with a number of men, and saw some natives at a distance, of a middle stature, quite black, and entirely naked, with whom the Dutch seem to have had no immediate intercourse. Prosecuting his search, *Vlaming* found the tin plate before alluded to, left by his countrymen in 1616, nailed to a post, and added the following inscription, as the French found it in 1801: "1697, on the 4th of February, the ship *Geelwink* of Amsterdam arrived here; *Wilhelm de Vlaming*, captain commandant; *John Bremen* of *Copenhagen*, assistant; *Michael Bloem Van Estight* of *Bremen*, assist-

* We are unable to ascertain the real orthography of this navigator's name, whether *Hartig*, *Hartighs*, *Hertog*, or *Hertoge*.

ant; the dogger *Nyctangh*, Captain Gerrit Colaart of Amsterdam; Theodore Hiernanns, of the same place, assistant; first pilot, Gerrit Gerritzen of Bremen: the galley *Art Hesselje*, Cornelius de Vlaming of Vlielandt, commander; Coert Gerritzen of Bremen, pilot. Our fleet sails hence, leaving the southern territories, for Batavia." The tin plate was discovered half buried in sand, attached to the remains of a wooden post, in 1801. The inscriptions were carefully copied, and the plate replaced on the north point of Dirk Hartighs Isle, where it was found, a new post having been erected for it.

Omitting other expeditions of less importance, we ought not to overlook the voyages of William Dampier, one of the most intelligent navigators who ever sailed from Britain. He twice revisited the Australasian regions, and landed on the coast of New Holland. In his first voyage he remained on it two months, from January 1688, and gives a deplorable picture of the country. It was flat, low, and sandy, and afforded no fresh water, except what was dug out of wells. Few fishes inhabited the sea; and the traces of no quadruped, excepting one, were seen. Scarcely any birds larger than a black-bird appeared; and he was unsuccessful in searching for fruits. The natives were the most miserable creatures in the universe, almost stark naked, and without houses or covering. They had no religion or government, and cohabited promiscuously. Dampier describes the savages as of extreme ugliness; and, in his second voyage in 1699, speaking of their custom of painting themselves, he thus expresses himself regarding an individual: "This, his painting, adding much to his natural deformity, for they all of them are of the most unpleasant look, and the worst features of any people ever I saw, though I have seen a great variety of savages." He observes, that New Holland is a very large tract of land, but it was not then fully determined whether a continent or an island; he was certain, however, that it joined neither Asia, Africa, nor America.

The unfavourable appearances exhibited by the greater part of the coast of New Holland, and the islands in its vicinity, restrained those nations, to which they were best known, from repeating their voyages towards them. But, while little progress had been made in exploring this part of Australasia, some others had occasionally been visited; and of the whole, it is not unlikely that the islands of Papua, or New Guinea, were the first discovered by navigators. A Portuguese officer, Don Jorge de Menezes, in a voyage from Malacca to the Mulocca Islands, to the command of which he had been appointed, wintered in a port immediately north, it would seem, of the great land of Papua, in 1526. This port was probably in one of the islands close to it. Other islands are mentioned, and all are said to be inhabited by the Papuans, or Papoos, the name by which the natives are now known.

A squadron, fitted out in the year 1526, for the purpose of discovering spice islands in the South Seas, sailed from Mexico, under the command of Alvarez de Saavedra, a Spaniard. A long time seems to have been occupied in this search; in returning from which, Saavedra discovered the land of Papua, or the adjacent islands. Believing that the country which he saw abounded in gold, he called it the *Isla del Oro*; it afterwards received the name of New Guinea, not from this source, but, as some affirm, from navigators thinking it opposite to Guinea, on the coast of Africa, or from a supposed resemblance between the inhabitants of the two countries.

Saavedra found them black, with short curled hair, and going naked. Their civilization even then far exceeded the state of most of the present natives of Australasia, for they had not only swords of iron, but other arms of the same metal. Saavedra, after remaining a month here, ran along the same land 100 leagues to the southward. Some canoes from an island then attacked his ship, in consequence of which he took three of the people prisoners. Next year, 1529, he brought them back in another voyage. Whenever they recognised their native island, two leapt overboard, and swam away; the third, more tractable, engaged to explain the pacific views of the Spaniards to his countrymen. As the ship approached the shore, he also leapt overboard; and the Spaniards had the mortification to see him killed while still in the water. If we can trust the accounts of this second voyage, Saavedra traversed more of the coast of Papua than any subsequent navigator has done. Other Spaniards also fell in with part of the Papuan territories in 1537 or 1538, where, it appears, they lost a vessel, and were made prisoners by the natives. Some of them were carried thence to the Moluccas, and there ransomed. Ruy Lopez de Villalobos ranged along the same coasts in 1543, when, ignorant of its having before been visited by Europeans, he conferred upon it the name of New Guinea. The country had an inviting appearance; and he anchored in several ports, where he obtained wood and water. Previous to reaching New Guinea, he fell in with an archipelago of islands, among which, it has been conjectured, the Spanish vessel was lost; we should consider it, however, to have been farther to the east. In 1616, James le Maire and William Schouten, both skillful navigators, in a voyage from the east, approached the coast of Papua. They anchored in a bay, where two villages stood on the shore, and had different interviews with the natives, from whom they obtained small quantities of provisions. They were remarkably diseased, not one being seen without lameness, blindness, or some other personal defect, which Le Maire and Schouten ascribed to the unhealthiness of the climate, as their houses stood eight or nine feet above the ground on posts. "These people," he observes "are the true Papoos, with black, short, and curled hair, wearing rings in their ears and noses, and necklaces of hogs' tusks: a wild, strange, and absurd people, curious to see every thing, and active as monkeys." Alvaro Mendana probably saw some of the islands near Papua, in 1595; also Tasman in 1642, and Dampier in 1699. Geographers have supposed, that what is described by both these authors as Papua, was in fact New Britain; and that Dampier, in particular, never landed on that island.

New Britain was certainly discovered by this latter navigator in 1699. Ranging along the coast to the most eastern part of New Guinea, he found it interrupted, and a lesser division, being an island, he called it New Britain. It may be productive of rich commodities, he says, and the natives might easily be brought to commerce. Owing to inconveniences which are specified by him, his voyage of discovery was soon abandoned. If New Ireland was known in the seventeenth century, it had then been very little explored. Mr Dalrymple, if we rightly understand his arguments, conceived the New Britain of Dampier to be the same as the Solomon Islands.

No part of all the Australasian regions has been the subject of greater doubt or controversy than the Arsa-cides, or Solomon Islands. Even their existence was

long denied after the original discovery, whence their history afterwards became an interesting topic of investigation. During the course of a voyage by Alvaro de Mendana, from Lima, in South America, for the purpose of discoveries in the South Sea, in the year 1567, he fell in with a great shoal in Australasia. This he called *Bancos de la Candelaria*, or *Candelmas Shoal*, which name it yet retains: it extended fifteen leagues, and the middle lay in $6^{\circ} 15'$ south latitude. Mendana next fell in with a large island, and several smaller ones, where, finding good materials, he built a brigantine, which he sent out on further discoveries. Other islands were discovered and examined; and he named the first whereon he had landed *Ysla Isabel*. In consequence of a design entertained by the Spanish government in South America, of establishing a settlement in Australasia, Mendana sailed on another voyage with four vessels in 1595. His discoveries among the islands had been considerable, owing to his residence there, and the services of the brigantine. In the course of again endeavouring to find them, he discovered an island to the eastward, which he called *Santa Cruz*, now known by the name of *Egmont's Island*. Viewing it as a suitable place for a colony, he landed and built a town, after slight rencounters with the natives. Mendana found means, however, to conciliate their friendship, and they supplied the colony with provisions; but an unlucky misunderstanding arose, when the chief was killed, and many misfortunes befell the Spaniards. Mendana soon afterwards died, and was interred in the church of the town which he had founded. The government devolved on his wife, who, deeming it expedient to abandon the settlement, sailed in quest of the Solomon Islands. After making an unsuccessful search for two of the principal islands, the people on board became impatient, and the vessels then altering their course, bore away for Manilla; and the governess thence sailed for New Spain. The result of Mendana's second voyage produced much embarrassment, for it was justly thought very extraordinary, that a number of islands, whose position had been specified with tolerable accuracy, could not be found again.

New Caledonia was not known at the period of which we are now treating, as it belongs to the discoveries of the eighteenth century; but the New Hebrides were known to Quiros in 1606. One of the islands was then called *Manicolo*, or *Mallicolo*, by the natives of the vicinity, as it is at the present time; and it is evident that he not only landed on the largest, but visited others in the vicinity.

New Zealand was discovered by Tasman, the navigator whom we have already named. On the 5th of December 1642, while searching for Solomon's Islands, he was obliged to alter his course, and on the 13th came in sight of a very high and mountainous country, which he believed the *Terra Australis*. He called it *Staaten Land*, and anchored in a bay on the northeast, where he had an interview with the natives. Supposing that a friendly intercourse could be carried on with them, he prepared to land; but a treacherous attack was made on him, wherein he lost several men, and thence called the place of his anchorage *Murderer's Bay*. He traversed some of the coast, which was of a pleasing and fertile appearance, and next stood to the northward, discovering some small islands in his way. This portion of Australasia is now called *New Zealand*.

Although many islands, rocks, and shoals, were noted

by the old navigators, we see, in this cursory retrospect, how very limited the knowledge of the Australasian regions was previous to the eighteenth century. There is a possibility that *New Holland* was discovered before the year 1600, but it is not yet supported by unquestionable evidence. In the subsequent century, various vessels had visited small portions of its coasts; and *Van Diemen's Land*, which had been observed to the south, was judged part of the same immense tract or continent. *New Britain* and *New Ireland* were almost totally unknown; the *New Hebrides* had been visited by one navigator; and *New Caledonia* was undiscovered. The position of *New Zealand* was hardly fixed, and only the general appearances of the country indicated. If there be any exception to these general remarks, it applies to the lands of the *Arsacides*; for few, if any, late navigators have left observations on them equally accurate with those of him by whom they were discovered. But a vast field of discovery opened in Australasia at the beginning of the eighteenth century; nor should this appear so remarkable, on considering the disposition and objects of the older navigators. Almost the whole commerce in the more genial climates of the new world was absorbed by the Spaniards, Dutch, and Portuguese. The purpose of the first and last, added to the acquisition of gain, and the desire of conquest, was the propagation of the Roman Catholic religion; that of the second was chiefly restricted to some mercantile establishment; and, if opportunities occurred, their scruples of making themselves masters of the territory were easily overcome. Unfortunately their first intercourse with newly discovered nations tended little to conciliation; they were guilty of acts and aggressions the most effectual to alienate regard. The savages, as they called them, were subjected to treatment more inhuman than would have been inflicted on brutes; they were despoiled of their scanty property, or forcibly made slaves. The gradual extension of commerce in the beginning of the eighteenth century, and its partition among the other European kingdoms, enlarged their views. The French and English learnt that it was one great source of wealth and prosperity, and having beheld what rival powers had done, many adventurers were attracted towards the Southern Ocean, in hopes of Spanish treasure. After their return, the advantage of settling in warmer and more fertile regions was deliberately canvassed, and then the expediency of exploring the wide extent of the globe hitherto undiscovered.

A few years after Dampier's return to Britain in 1700, two vessels were sent to the South seas, commanded by *Woodes Rogers*, an Englishman. Their design was the capture of some of the Spanish towns and shipping in South America, in which they fully succeeded. During 1710, the vessels, in one of which Dampier himself was pilot, passed through the straits of *New Guinea*, where he had been twice before: and from the observations made by Rogers among the islands, he was impressed with a high opinion of the benefit that would accrue from their products. Though many of the Dutch, and, perhaps, also the Spanish voyages towards Australasia, were cautiously withheld from public notice, there is one with which we are acquainted that was intentionally planned for the sole purpose of discovery. *Roggeveen*, a Dutch commander, in consequence of pursuing ideas originally suggested by his father, was sent out with a small squadron in 1721, to make discoveries in

Australasia. He had himself presented a memorial on that subject to the East India Company, or the government of his country, and was amply provided with whatever might be conducive to the success of his voyage. Roggewein unfortunately lost one of his ships just about the eastern limits of Australasia, and immediately afterwards discovered Aurora island, so named from coming in view of it as morning dawned. His particular design was to rediscover Solomon's islands, and the lands described by Quivos, from which particular incidents obliged him to desist, and steer a different course from the lands near Aurora island. He landed in New Britain in 1722, where he was attacked by the inhabitants with arrows, spears, and a shower of stones: and he concluded, from the address displayed by them in the use of arms, that they were inured to war. These people were of a yellow colour, tall in stature, slender, and with black hair hanging down to the girdle. The country appeared to him mountainous and well wooded, beautiful, fertile, and full of minerals and other precious treasures. He next trafficked with the inhabitants of Moa and Arrimoo, two islands not far from the Papuan coasts, so named by Schouten: all the inhabitants, men, women, and children, were armed with bows and arrows. They shewed extreme agility in their motions, and came without the smallest indications of fear to barter their commodities. Yet hostilities ensued from the Dutch going ashore, and indiscreetly cutting down the cocoa nut trees: though, when about to sail, traffic was renewed with mutual confidence. Roggewein thus continued his navigation in a region of innumerable islands, which on that account he called the Thousand Islands. These were inhabited by people black and hairy, and of a treacherous and malevolent aspect. They were entirely naked, except in wearing a girdle about two inches broad, with hogs teeth interlaced: and they had strings of the same teeth around their legs and arms. On the head they wore a hat of rushes, ornamented with bird of paradise feathers.

Approaching nearer to our own times, we find that several discoveries by the former navigators of Australasia have been confirmed. The groupe of islands containing Santa Cruz, where Mendana landed in 1595, was visited by Captain Carteret in 1767, while on a voyage of discovery from England. Falling in with a cluster of seven islands, he anchored on the largest, but his people committed indiscretions similar to those of the former navigators, hostilities commenced with the natives, and from constant warfare ensuing, Captain Carteret was obliged to depart without supplies. He named the whole groupe Queen Charlotte's islands, and changed the name of Santa Cruz to Egmont island. Captain Carteret also found a strait, dividing New Britain from New Ireland, and sailed through it.

M. de Bougainville, a French officer, having gone out on a similar voyage of discovery, found himself within the limits of Australasia in May 1768. After giving names to some islands in his way, he landed on Lepers island, on which he was induced to bestow that name, from the natives in general being overrun with leprosy. They were either black or mulatto coloured, ill made, with thick lips, frizzled hair, and small eyes. On the neck they wore plates of tortoise shell by way of ornament, and rings of a substance resembling ivory as bracelets on the arms. Few women were seen, but they were equally disgusting as the men in appearance. In May M. de Bougainville sailed along the north coast

of an extensive land, low, and covered with trees. Many natives were seen on the beach, but although some canoes put off, none would venture on board his vessels. The French, however, prepared to land in a beautiful bay, on which they were attacked by the inhabitants, whom they treated with much rigour in retaliation. M. de Bougainville, ignorant that this part of Australasia had been already visited, and having found a number of islands lying near each other, called the whole the *Archipelago of the Great Cyclades*. The more extensive coast was afterwards proved to be the *Tierra Austral del Espiritu Santo*, where Quivos had remained a month. Warfare seemed to pervade these islands, as the natives would part with none of their arms except a few arrows.

M. de Bougainville, in a north-west course from the Tierra Austral del Espiritu Santo, discovered a new region of Australasia. His approach to the land was indicated by a delightful odour in the night, and in the morning a beautiful country was disclosed to view, consisting of plains and groves extending along the shores, and lofty mountains of different elevations in the interior. He was prevented from visiting so desirable a country, bearing every mark of riches and fertility, for both disease and famine had reduced his crew. Standing along the south shore, he saw several islands, and after doubling a cape on the east, he called the land *La Louisiade*. Here, for the sake of preserving connection, it may be remarked, that our present knowledge of Louisiade is infinitely more imperfect than of most other Australasian territories. Since that period it has seldom been recognized, and some geographers have supposed it an extension of the coast of Papua. Two French vessels, the *Boussole* and *Recherche*, traversed the north coast in 1793, but except in ascertaining that there were numerous flats, shoals, and islands indistinctly characterised, no important discoveries were made. The natives had woolly hair and olive coloured skins: they were stark naked, excepting a kind of girdle, and large leaves before. Some of them ornamented their woolly hair with tufts of feathers, and wore cords wound several times tight round their bodies, intended, as the French conjectured, to support the muscles of the belly. The faces of many were smeared over with charcoal, and they had a bone through the septum of the nose. They seemed extremely fond of perfumes, and most of the articles procured from them were scented. These savages displayed great dexterity in steering their canoes, and could sail swiftly round the vessels. They were very earnest that the French should go on shore, where their houses stood on posts, five or six feet from the ground, like those of the Papuans.

Further discoveries were made in Australasia by M. de Bougainville. A few degrees north of Louisiade he found a number of islands which bear his name, as also straits to the north-west of Solomon's islands. One which appeared to have a good harbour, he called *Choiseul island*, and sent out boats to examine it. But while his people were engaged in sounding, the natives, who had previously shewn a hostile disposition, suddenly attacked them with ten canoes. They were armed with bows, spears, and shields; the latter consisting of plaited rushes, and so thickly interwoven as to be impenetrable by arrows. These savages advanced in good order, and dividing their force, attempted to surround the boats, and even after receiving the fire of musketry, continued to throw lances and discharge their arrows;

facts which at once proved their intrepidity, and their familiarity with war. Their bravery, however, was unavailing, and two of their canoes, containing ample store of arms, were taken by the French. The natives were black, with curled hair, dyed white, yellow, and red. Those of another island went entirely naked; the short woolly hair of many was also stained red; and white spots were painted on different parts of the body. M. de Bougainville next made the coast of New Ireland, and anchored in a bay, formerly named Gower harbour, by Captain Cartaret, and now called *Praslin's Bay*. Having afterwards traversed the north coast of New Guinea, he directed his voyage homewards.

Nearly about the same period, M. de Surville, also a Frenchman, undertook a voyage to Australasia on some commercial speculation, with the special nature of which we are unacquainted. He commanded a vessel of considerable size and force, and sailed from Pondicherry with a cargo in June 1769. On the 6th of October, being in $6^{\circ} 56'$ south latitude, and longitude $151^{\circ} 30'$ east of Paris, he saw an island which he named *First Sight island*, and then came in view of land with a great chain of mountains extending as far as the eye could reach. The latitude of the island was fixed at $7^{\circ} 15'$, and its longitude 155° east of Paris. Four islets and a high mountain seemed to form the mouth of a capacious bay, which Surville determined to explore. It proved to be uninhabited, but it abounded in fruit trees, and numerous birds of beautiful plumage. Fifteen leagues south of *First Sight island* high mountains were seen, and Surville, proceeding along, passed many islands, which he was deterred from approaching by the state of the shore. At length he anchored in a fine harbour with reefs and islands at the entrance, which he named *Port Praslin*. Various interviews took place with the natives, whose early display of hostile intentions was averted by the conciliatory conduct of the French. Nevertheless, it quickly appeared how little they merited confidence, from leading their visitors into an ambuscade, where an encounter ensued, and thirty or forty of their own number were killed. Several of the French were wounded, and afterwards died. The ferocious disposition of the natives prevented M. de Surville from obtaining an intimate knowledge of the country, which was extremely inviting. He observed among the plants wild coffee, the cabbage tree, different species of almonds, cocoa nuts, and other fruits in abundance: the shores were likewise well stored with fish, turtles, and their eggs: and though no quadruped was seen, the wild boar was said to inhabit the woods. The people were of ordinary stature, strong and masculine; some were perfectly black, with soft woolly hair, others copper-coloured, with lank hair, and all of ferocious aspects. Most of them powdered their hair and eye-brows with lime, and painted a white line over the eye-brows. They carried clubs, bows, arrows, and spears, and as a defence had shields of wicker work, ornamented with tufts, or tassels, of red or yellow straw. Their canoes were skilfully made by the union of several pieces, the joining of which were secured by mastic. M. de Surville, by a stratagem, captured a young savage, who testified a good and tractable disposition, and became much esteemed in the vessel. He was carried to Lima, but whether or not to France, we are ignorant. From him much interesting information was obtained respecting the manners and products of his country. It was governed by a chief, who enjoyed unbounded au-

thority, and the respect shown to him was said to be so great, that the simple treading on his shadow was punished with death. M. de Surville was now amidst an archipelago of islands, in which he judged there were good harbours and fertile grounds. He discovered a detached island in $9^{\circ} 45'$ S. Lat. and $4^{\circ} 20'$ E. of Port Praslin, which, from the calms and adverse winds he experienced, he called *Isle des Contrariétés*. Canoes from it surrounded his vessel, but the natives were uncommonly shy: they were quite naked, and seemed of different races; some with remarkably large heads, resembled African negroes. Their apprehensions were quickly dispelled, and the chief came on board; his canoe was of workmanship singularly neat, inlaid with different coloured wood and pieces of mother of pearl. On comparing the result of M. de Surville's observations, it has been concluded that he was navigating among the Solomon islands; and it has justly been regretted, that he was prevented by untoward circumstances from completing their survey. The whole countries which he discovered were named by him the lands of the Arsacides; and to warn future navigators of their treacherous inhabitants, he left inscriptions in Port Praslin. After losing half his crew by disease, M. de Surville was unfortunately drowned when going ashore at Lima.

M. Marion du Fresne was employed by the French government to conduct a native of Otaheite to the Isle of France, and also to proceed on a voyage of discovery. But the Otaheitan, who had been brought to Europe by M. de Bougainville, having died at the island of Bourbon, M. Marion altered the course of the two ships under his command, the *Mascarin* and *Castries*, and in February 1772, found himself within the region of Australasia. He spent six days in Frederic Henry's Bay, Van Diemen's Land, searching in vain for fresh water, and then made the bay of islands in New Zealand in the subsequent May. There he exerted himself to conciliate the good will of the natives, and apparently succeeded; but after living thirty-three days on the most friendly terms, they, without any evident cause, found means to surprise two boats, and cruelly massacre 27 persons, among whom was M. Marion himself. The place where this happened, the French called Traitor's Bay. They took the full measure of vengeance on the natives, and then, instead of prosecuting the voyage of discovery, sailed for the islands of Rotterdam and Guam.

It had now become of sufficient importance among some of the European nations to prepare expeditions for the purpose of geographical discovery, under the patronage of their respective governments. Of this kind was that under the command of M. de Bougainville; and those from Britain under Byron, Wallis, Carteret, and Cook. Such expeditions were less liable to failure from the precautions taken in fitting them out, and the strict observance of subordination; for several of the former navigators whom we have named, were obliged to desist from further enterprise, owing to the murmurs of their crew. The voyages of Captain Cook are too well known, and too easily accessible, to require any notice in illustrating the progress of discovery in Australasia. It is only incumbent on us to observe, that, independent of the new regions which he himself explored, he cleared up the doubts of preceding navigators concerning different Australasian countries, and accurately fixed their position on the globe. In his first

voyage, he visited the coast of New Holland, and gave names to numerous islands, bays, and capes. In his second, he came in sight of Aurora island in July 1774, which he found lay in $168^{\circ} 39'$ E. longitude, and then saw Lepers isle, which appeared to be cultivated; but none of the inhabitants would come on board. He then landed at Mallicolo, the same which had been mentioned by Quivos, where the people put little or no value on European articles. They exhibited singular proofs of honesty; but they seemed to distrust their visitors, until they saw preparations for departure. They were a deformed race, with long heads, flat faces, and monkey countenances; and they wore cords tied so tight about the belly, that Captain Cook compares their appearance to that of an overgrown pismire. Landing at another island, Erromangoi, 2° south of Mallicolo, he was treacherously attacked by the natives; but a friendly intercourse was established with the isle of Tanna, the inhabitants of which supplied him with provisions. Most of them had good features and agreeable countenances. Apparently, the women performed the most laborious occupations; they wore a petticoat down to the knee, necklaces, ear-rings, and amulets. Here were seen a volcano and hot springs. In August of this year, 1774, Captain Cook anchored in a great bay of the *Tierra del Espiritu Santo*, sixty miles in extent of coast. He effected an accurate survey of the whole island, which he found twenty-two leagues long, twelve broad, and sixty in circuit. The island of Mallicolo he found eighteen leagues long and eight broad, fertile, and well inhabited. Of the chain of islands which he here visited, the *Pic de l'Etoile* is the most northern, and the island of *Annatom* the most southern. The whole lie between the latitude of $14^{\circ} 29'$ and $20^{\circ} 4'$ south; between $166^{\circ} 41'$, and $170^{\circ} 21'$ of east longitude, and extend 125 leagues from north north-west to south south-east. He called these islands the New Hebrides; thus changing their name a third time. Leaving the *Tierra Austral*, he next discovered an extensive country of Australasia, apparently about eighty-seven leagues in length, and about ten in breadth, which he called New Caledonia. The people were courteous and friendly, and, unlike any other nation in the South Sea, they were not the least addicted to pilfering. Their houses were in general circular, somewhat resembling a bee-hive, and hilly as close and warm: the entrance was by a small door, or long square hole, just large enough to admit a man bent double. Some of the houses had two floors, one above the other, and most of them two fire-places. Captain Cook, after discovering the Isle of Pines, Botany Isle, and several inconsiderable objects, left the coast, and made sail for New Zealand. In the way thither, he discovered Norfolk island, which has since acquired greater consideration, though its whole extent does not exceed 11,000 acres; but this is amply compensated by its fertility. It was then uninhabited, and Captain Cook concluded that no human being had previously been there. At the time when we make these remarks, it supports a numerous population, though not of Australasians, and is chiefly in a high state of cultivation. Having made a short stay at New Zealand, Captain Cook left Australasia.

During his third voyage round the world, he also visited the same regions in the year 1777. Some of the inhabitants realised the fables of old, by sheltering themselves in the trunks of large trees excavated by fire, while the exterior was sound, and vegetation con-

tinued. Such were their sole habitations. He anchored a considerable time in Adventure Bay in Van Diemen's Land, and then made the coast of New Zealand, where he obtained numerous interesting illustrations of the nature of the country, and the manners and dispositions of its inhabitants. Australasia was less the object of this voyage than the north-west coast of America, for which he departed in the end of February.

While new countries were sought for with such avidity in the southern latitudes of Australasia, some of the northern ones were also explored. Captain Forrest, an intelligent navigator, undertook a voyage from India, the leading design of which was to ascertain the practicability of forming a settlement on an island near the northern promontory of Borneo. This voyage was performed in a vessel of only ten tons, between the years 1774 and 1776. Captain Forrest examined the north coast of Waygiou, extending fifteen leagues, the extremity of which is immediately under the line, and he anchored in Offak harbour in $10'$ N. latitude, and $127^{\circ} 44'$ E. longitude. After visiting several small islands, the inhabitants of which are so well provided with natural productions as to neglect the cultivation of the earth, he gained Dory harbour, on the north coast of Papua. When he lay off the mouth of it, the natives came on board, having their hair, which was sometimes ornamented with feathers, extended to such an uncommon size, that the largest circumference of it measured about three feet, and the least about two and a half. The hair of the women was disposed after a similar fashion, though not expanded to such a degree; and only the left ear was pierced, in which were suspended small rings. Their great houses were built on posts, several yards within low water mark, and capacious enough to contain many families under the same roof. The men and women wore little clothing, and the boys and girls went entirely naked. The people of Papua and the neighbouring islands are accustomed to war, and they have been known to collect such a considerable force as to alarm the Dutch for the safety of their colonial possessions. The natural history of these islands has been illustrated by M. Sonnerat, who, nearly about this period, spent some years among them. Birds of paradise frequent them, and are regarded as valuable articles of traffic. M. Sonnerat obtained six different species, four of which he has engraved. In Valentyn's history of the East Indies, there is a long and minute account of these birds, copied by Captain Forrest, and, since his time, by other authors. M. Sonnerat represents the Papuans as brave and warlike, but cunning, cruel, and treacherous. Their aspect is hideous and terrific, and most of them disfigured by cutaneous disorders. With the different countries which they inhabit, it may be observed, we are very little acquainted: They are nearly the most northern of Australasia.

Don Francis Anthony Maurelle, during a voyage in 1781, where expedition was principally in view, crossed the line towards the northern parts of New Guinea, and steered a south-east course through some portion of Australasia. He discovered an island, the north coast of which extended eleven leagues, apparently in about 150° of longitude east of Paris, and between 2° and 3° of south latitude. The natives resembled the negroes of Guinea, in colour, hair, lips, and eyes. They seemed to be in great want of subsistence, and to draw their supplies chiefly from the sea. Their only arms were

bows and arrows, the latter pointed with clumsy pieces of flint. This island was called Maurelle by Don Joseph Basco, and two of six others, discovered on the same day, he called St Michael and Jesus Maria. He fixed the position of Mathias island at $144^{\circ} 54'$ east of Paris, and steering through different clusters of islands on the north of New Ireland, he appears to have approached the Arsacides, and advanced towards Candlemas Shoals. But the particulars of his voyage are so indistinctly narrated, that we cannot positively ascertain either the discoveries which he made, or the countries which he visited.

In the years 1786 and 1787, La Perouse navigated some portion of Australasia. The only accounts we have of his voyage were transmitted by means of M. Lesseps from Botany Bay.

In July 1788, three ships, commanded by Lieutenant Shortland, sailed from Botany Bay for England. Owing to the advanced state of the season, he resolved, instead of steering a southern course, to go to the northward, and either pass through Endeavour Straits to the north of New Holland, or go round the east coast of New Guinea. Not long after leaving the settlement, he fell in with an island called *Simbo* by its natives. They invited him on shore, shewing him different kinds of provisions as an incitement; but the length of the voyage precluded his compliance with their solicitations. Standing on his course, he discovered other islands, and entered a strait; and supposing himself the first navigator who had penetrated it, he called it Shortland's Straits. It is unnecessary for us to examine the further progress of his voyage; for M. Fleurieu, in a learned critical discussion on the subject, has proved, that *Simbo* is the same as *Choiseul* island; the straits, those before called *Bougainville's Straits*; and the other islands, part of the lands of the *Arsacides*. Thus, whatever geographical illustrations may arise from Lieutenant Shortland's observations, they cannot be ranked among the discoveries of modern navigators. Nor should this occasion our regret, because, in claiming the credit of priority to his countrymen, M. Fleurieu has rendered essential services to the geography of Australasia.

In the year 1791, captain Vancouver explored 110 leagues of the south-west coast of New Holland; where he discovered King George's Sound, and some clusters of small islands. The former lies in latitude $35^{\circ} 5'$, S. and in $118^{\circ} 17'$ E. longitude. Mr Broughton, who commanded another vessel on the same expedition, discovered a fertile and delightful island, situated in S. latitude $43^{\circ} 49'$, and $183^{\circ} 25'$ E. longitude, which he called *Chatham* island. The hostility of the natives, who were of a brown colour, middling size, and stoutly made, prevented more minute investigation.

A late voyage by the French in search of their unfortunate countryman La Perouse has also thrown much light on those distant regions. Two vessels, the *Recherche* and *Esperance*, sailed from France in September 1791, fully stored with all that was most likely to ensure the safety and success of the undertaking. In April 1792, they came within the limits of Australasia, and were some time occupied in observations on Van Diemen's Land, when they thought the south cape was separated from the main land: they also discovered a great harbour which they called *Port D'Entrecasteaux*. They next saw the *Isle of Pines*, which had received its name from high rocky elevations resembling trees at a

distance, and laid down its position in $22^{\circ} 43'$ S. latitude. They then ran along an immense chain of reefs extending 324 miles on the coast of New Caledonia, which, in the view of the French navigators, presented a more inviting aspect than the original country of that name. Their attention was directed to the south-west coast, captain Cook having surveyed the land only to the north; and, in the course of their examination, they saw many mountainous islands, and detached rocks, with their points above water, encircled by dangerous reefs. The difference was no more than $4'$ between the position of New Caledonia as fixed by Cook and themselves. In July 1792, they saw the lands of the *Arsacides*, and ascertained the *Treasure Islands* to be five or six in number, or more, though when seen from a distance, they may be mistaken for only one. They lie in $7^{\circ} 23'$ S. latitude. The natives of *Bouka* Island trafficked for articles on board, parting with their arms for handkerchiefs and pieces of cloth. They were of a gay and lively disposition, and the French remarked, that they pronounced several Spanish and English words. The possibility of some intercourse with Europeans was thence inferred, and they shewed themselves acquainted with the use of iron. The French landed on *Cocos* island, and *Laig*, near the coast of New Ireland; in the former they found a tree nearly a hundred feet high, though but three inches in diameter: and so hard as at first to resist the heaviest blows of an axe. What is still more singular, when the pith occupying its centre was taken out, the thickness of the wood did not exceed four-tenths of an inch. The French then anchored in *Carteret* harbour, in New Ireland, which is surrounded by lofty and precipitous mountains, containing marine substances up to the very summit. This harbour forms a kind of basin, where clouds coming from the mountains are arrested by a calm, and there deposit their contents; which is the real source of the rains experienced by navigators. Sailing thence to the *Admiralty* islands, the situation of several places was determined in the way. A friendly intercourse was opened with the natives, who shewed a great desire to possess European articles. One island being cultivated to the highest part, and pieces being inclosed with fences, they were led to believe that the natives were acquainted with the right of property in land. A mountainous island occupied the centre of the whole groupe, and the same was the case with the *Hermit* isles, thirteen in number, which were next visited. The inhabitants of these and other islands manifested excellent dispositions: their chiefs punished dishonesty towards their visitors, and they approached the vessels unprovided with arms. Nearly under the line a number of other islands were discovered, all connected by chains of reefs, low, and covered by lofty trees, growing quickly and vigorously. After navigating among them, the vessels sailed to the *Papuan* islands, the situation of several of which was determined. In the subsequent year, 1793, the French made *Lewin's land* on the coast of New Holland, where they found that the latitudes had been ascertained with remarkable precision by its first discoverers. Many small islands were seen, which had not been previously visited; and having traversed several degrees on the south-west, they anchored in *Port D'Entrecasteaux*, as they had done in the preceding year. The accurate and interesting remarks then made on the natural history of the country, and disposition of the inhabitants, will be found at large in the works which

tain them. The French next sailed for New Zealand, and fixed the latitude of the *Three King's Islands* at $34^{\circ} 20'$ south; they were particularly desirous of obtaining the New Zealand flax, from supposing that it would succeed in Europe, but they did not put their design in execution. An island discovered in $29^{\circ} 20'$ S. latitude, near the coast, of a triangular figure, was called *Recherche*. Precipices were seen in the interior, and trees growing on the summit of the highest places. It is one of the most eastern islands of Australasia. Some time afterwards the French got sight of Erronan, the most eastern of the New Hebrides, and made the island of Tanna, where they enjoyed a brilliant spectacle, arising from the vivid flames emitted during the night by the volcano. Having made New Caledonia, their observations were resumed, and circumstances led them to conclude that this coast had been fatal to their countrymen. Besides the natives, they saw here several savages of other parts, acquainted with the use of iron, and much more intelligent, whom they conjectured to have come from the island of Beuprè, discovered during their voyage hither in $20^{\circ} 14'$ S. latitude. From New Caledonia the French repaired to the Arsacides, and then passing Louisiade, as already mentioned, steered for the coast of New Britain, where they discovered several mountainous islands before unknown. The navigation of the western coast was replete with danger. Keeping to the north, they anchored at the island of Waygiou, called by the natives Ouarido, which is covered with large trees, and mountainous throughout. The natives went nearly naked: the chiefs only being clothed in stuffs obtained from the Chinese, and some had silver bracelets. From the great value set on iron, it was suspected that they were acquainted with some method of forging it; but the European commodity which they chiefly coveted was red cloth. Their huts, which were built of bamboo, and covered with reeds, resembled those of the Papuans, in being supported several feet above the ground on posts. The French were visited by several chiefs, one of whom even ventured to sleep on board the *Esperance*: but whenever preparations were made for getting under way, he precipitately threw himself into the sea. The Dutch had five months before treacherously seduced his brother into captivity, when he was invited to partake of an entertainment on board of their vessel. Although this voyage has not added much to geographical discovery in Australasia, it is valuable on account of its illustration of the natural history of the different countries, and the accuracy with which the astronomical observations seem to have been made. The two vessels lost nearly half their men, which affords a striking demonstration of the superior skill of British officers, who have been known to circumnavigate the globe, and hardly lose one of the crew. We are indebted to M. Labillardiere for an account of this voyage.

During the interval at which we are now arrived, between the expeditions of M. de la Perouse in 1786, and M. Labillardiere in 1794, the occasional voyages of the English between New Holland and Britain, or her eastern possessions, had been productive of some less important discoveries. In the course of the extraordinary, or rather the extravagant voyage performed by the ship *Duff*, a groupe of about eleven islands, lying in $9^{\circ} 57'$ of S. latitude, and 167° E. longitude, was discovered in 1797. The two largest were entirely covered with wood, and bore the appearance of great fertility. The

natives were stout and well made, and of a copper colour. Their canoes were twelve or fourteen feet long, only fifteen inches wide, and made of a single tree sharpened at the ends.

But we hasten to a voyage of greater importance, by captain Flinders, which ascertained the fact of Van Diemen's Land being no part of New Holland. The merit of this discovery does not belong to him alone, for Mr Bass, surgeon of his majesty's ship *Reliance*, had previously made an excursion in an open boat to the southward of Port Jackson, towards the end of the year 1797. He sailed as far as 40° of south latitude, and visited every opening in the coast during his voyage. Between 39° and 40° of south latitude, he thought he had sufficient reason to believe that there was an extensive strait, or rather an open sea: and conjectured that Van Diemen's Land consisted of a groupe of islands south of New Holland. The want of a better vessel prevented him at that time from completing their circumnavigation. However, this was soon remedied by the governor of the English colony sending out captain Flinders, suitably provided, on a voyage of discovery, accompanied by Mr Bass. They sailed for Van Diemen's Land in October 1798, and visited Furneaux's islands, discovered in 1774, by the captain of the *Adventure*. Preservation Island, which had received that name from proving an asylum to a shipwrecked crew, on being particularly examined, exhibited a singular kind of petrification that had taken place in the stumps of the trees. It extended far above the ground, but did not penetrate more than two or three inches downwards into a sandy soil. On standing further into the supposed strait, they discovered a large harbour, which they called Port Dalrymple, in S. latitude 41° , on the north of Van Diemen's Land. Though they were able to make interesting remarks on the animals, vegetables, and minerals, the shyness of the inhabitants prevented any intercourse or communication with them. To judge by appearances, they seemed even in a greater state of barbarity than the natives of the neighbouring continent, and to be quite unacquainted with navigation in the rude canoes constructed by the most savage of the Australasians. One island, fifteen or twenty miles in circuit, was next discovered, and another in latitude $40^{\circ} 24'$, E. longitude $143^{\circ} 2'$, which, from the innumerable quantities of albatrosses frequenting it, they called Albatross island. The wings of these birds expanded between seven and nine feet. Other ten islands were discovered in the vicinity, and the whole received the general name of Hunter's isles. In this latitude the navigators concluded that they had passed through a strait, between one and two degrees in width, which separated New Holland from Van Diemen's Land. The appearance of the coast changed; a great swell rolled in, and a surf breaking on a bold shore announced the vicinity of the open ocean. On the 8th of January they passed the southwest cape of Van Diemen's Land; and what had hitherto been universally described as part of New Holland, proved a large island, completely separated from the continent. After being out twelve weeks, they arrived at Port Jackson. The discovery of this passage, named by the governor Bass's Straits, promised great advantages. In voyages from New Holland to the Cape of Good Hope, it was judged that a whole week would be gained, and some mariners affirmed that no other course would ever afterwards be taken. In the year 1804, the China fleet entered the strait on the 28th of

October, passed it in safety, and reached the coast of China on the 28th of December. The real value of such a discovery will be best appreciated by the importance attached to it by our countrymen in the remote settlements of Australasia. There, we are told by recent French navigators, that the remains of the vessel which made the discovery are preserved with a kind of religious veneration; and that parts of the keel, made into various little articles, are presented to foreign officers as donations, which no pecuniary recompence can obtain.

Captain Flinders was soon afterwards engaged in subsequent voyages of discovery. In the earlier part of the year 1802, he surveyed King George's sound, and the west coast of New Holland, from Lewin's land to Western Port. He again left Port Jackson in July of the same year, and sailing through Torres or Endeavour straits in thirty-six hours, arrived in the gulf of Carpentaria in the latter end of the season. The sickness of his crew obliged him to interrupt this survey, and sail for Timor in March 1803, but soon returning, he completed the circumnavigation of New Holland in eighteen months. In August 1803, he again sailed with the command of the Porpoise and Cato, and a third ship in company. Both the former were wrecked on a reef of rocks in $22^{\circ} 11' S.$ latitude, and $153^{\circ} 13' E.$ longitude, nearly 800 miles from Botany Bay. A party of his men escaped thither in an open boat: and after procuring assistance from that settlement, captain Flinders saw the remainder, and all his officers, safely embarked for China. Impatient to convey his papers, plans, and charts of discovery to England, he embarked once more from Port Jackson in a vessel of only 19 tons burden, which carried him across the great ocean to the Isle of France, where, though he possessed passports from the French government, he was detained with all his dispatches. In consequence of an application by the Royal Society of London to the National Institute, an order to liberate captain Flinders was transmitted from the French government to the Isle of France in 1805 or 1806. The governor, however, declined compliance, on pretence "that the English captain was so well acquainted with his island, he would be able to take it;" and we believe that captain Flinders still remains a prisoner.

A small vessel, the *Lady Nelson* of 60 tons, built on a particular construction, sailed from England under the command of Lieutenant Grant, in March 1800, on a voyage of discovery to the Australasian shores. In December, she made the coast of New Holland, where a fine fertile looking country came in view, covered with trees in some places down to the water's edge. Lieut. Grant followed the coast from $38^{\circ} S.$ latitude, and longitude $141^{\circ} 20' E.$ through Bass's Straits to Botany Bay; and fixed the geographical position of several islands and headlands, which he discovered in the route. In March 1801 he sailed from Sydney Cove, and made an accurate survey of the coast from Western Point, in latitude $38^{\circ} 32' S.$, and longitude $146^{\circ} 19' E.$ to Wilson's promontory, a great cape stretching twenty miles into the sea. This cape, which is the most southern point of New Holland, was discovered by the Captain of an East Indiaman. In May 1801, the *Lady Nelson* made a voyage to the northward of this settlement to Coal River. Abundance of coals appeared on a spot covered by low grass for many acres; and they could also be gathered on the shore at low water. Copper and iron ore were likewise discovered. Peculiar circumstances, that

would appear, opposed to Lieutenant Grant's own opinion, prevented the further extension of the survey in which he was employed.

Here we have given but brief abstracts of the discoveries by English navigators, while accounts by those of foreign nations are more detailed, from being less accessible. Certain it is, however, that no voyages, if viewed with the strictest impartiality, can be compared with the expeditions which sail from our own country. This decided superiority of the English, their settlements, and discoveries in Australasia, excited the emulation of the French. An expedition was, therefore, planned with the utmost care, chiefly for the purpose of exploring the Australasian regions. Its object was great and comprehensive, perhaps attempting to embrace, in the course of a short and limited period, what might more reasonably have been the operations of many successive years. First, the southern part of Van Diemen's Land was to be approached; Cape South doubled; D'Entrecasteaux harbour examined; all the rivers that could be found were to be navigated; and the whole eastern coast of this great island surveyed. After an examination of Bass's straits, and Hunter's isles, it was proposed to run along the south-west coast of New Holland, to penetrate behind the islands of St Peter and St Francis, where the existence of a strait reaching to the gulf of Carpentaria was suspected. The position of Lewin's, Edel's, and Endracht's land was to be fixed, and Swan's river navigated to the utmost extent: the Abrolhos, where Pelsart was wrecked; Shark's bay, De Witt's land, King William's river, the Romarin islands, were to be minutely inspected; and this part of the voyage was to terminate at Cape North-West. The future object of the expedition, so far as respects Australasia, was a survey of the coast of New Guinea, and a search for the strait supposed to divide it into two equal parts consisting of several islands. Next advancing by Endeavour straits, it was to reach the eastern point of the great gulf of Carpentaria; to visit the mouths of the many rivers which were said to discharge themselves into it: then traversing Arnhem's and North Van Diemen's Land, to terminate the second part of the voyage also at Cape North-West. Having completed these extensive operations, the expedition was to navigate the Indian ocean, determine the longitude of Tryal islands, and then proceed to the Isle of France.

Though we are yet but partially acquainted with the whole result of this expedition, we shall briefly relate some of the particulars, which have recently come to our knowledge. Two vessels, the *Geographer* and *Naturalist*, sailed in October 1800, from Havre de Grace. Much was to be expected from the scientific department; for the French, paying infinitely more attention to it than the British government had done in the later voyages of discovery, sent out no less than 23 individuals, well qualified in all the different branches of science. The vessels made Cape Lewin, the most western point of New Holland, in latitude, $34^{\circ} 7' 30'' S.$ in the end of May 1801, where the lands were dark, low, and sandy. Endracht's land they found sterile, and surrounded by reefs: then entering Shark's bay, they landed on Bernier's island, which was among their earliest discoveries. The substance of the island is chiefly calcareous, with shells, principally univalves, incrusting in masses of rock, sometimes 150 feet above the level of the sea. Vegetation, from the nature of the soil, was low and languishing; a kind of fig-tree, with fruit

hardly larger than a nut, and several small odoriferous mimosæ, were seen; also a sort of spinifex, consisting of innumerable sharp, slender leaves, dangerous to touch for wounding the flesh. It grows in the most arid places, is easily decomposed from the multiplicity of spines, and in this decomposition is the essential source of the soil of the island. The striped kangaroo, the most beautiful of its singular race, swarmed here, as well as on two neighbouring islands. Some young ones were taken, but all of them died except one, which lived until the expedition reached Timor, when it perished by accident. The French, after anchoring in Dampier's bay, behind a peninsula, which had hitherto been supposed an island, saw King William's river. It issues from a sterile region; and, from its confined and dangerous entrance, they concluded that it was of much less importance than had been represented. Seven low, barren, sandy islands were then discovered, which the French called the Rivoli islands, to perpetuate one of their victories: and the north-west Cape of New Holland, from which projects an extensive reef, with a sea violently breaking on it, they named Cape Murat. At Cape Murat, De Witt's land commences, and extends to the north cape of this immense continent, thus comprehending a tract of 16° in latitude, and 15° in longitude. It is supposed to have been discovered by a Dutch navigator in the year 1616, 1623, or 1628. The French now discovered a great archipelago; the islands composing which, in general, appeared barren, and many of them encompassed by rocks and shoals. Incredible dangers here assailed them: the vessels were driven towards the breakers white with foam; while the calms which prevailed, interrupting their manœuvres, increased the difficulties of an intricate navigation. In the course of it, Dampier's observations concerning the fineness of the weather, and the singular serenity of the heavens, were verified. The air had never appeared so pure and so free of vapours and humidity. Few of these islands were of large size; some were basaltic, and seemingly of volcanic origin; others, sandy, white, and sterile, rose under a thousand different shapes, several of them resembling immense antique tombs. Names were bestowed on a great number, as Forbin, Commerson, Colbert, Buffon, Cassini, Bernouilli, La Place; and the whole were comprehended under the denomination of *Bonaparte's Archipelago*. Disease had already begun to make ravages in the vessels, which forced their commanders to leave the Australasian regions to recruit their strength at Timor. After residing some months at that island, they made D'Entrecasteaux's straits in 62 days, on their return. The discovery of these straits they consider the most remarkable and important of any connected with Van Diemen's Land: whence they were judged deserving of the greater notice. Thirty-six days were occupied in observations, during which many acquisitions were made to natural history; and several geographical errors corrected. Tasman's isle proved only to be a peninsula; but they found D'Entrecasteaux's geographical labours so perfect, that nothing could exceed them. Departing thence, Maria's island, discovered by Schouten in 1642, was surveyed. It is situated in $42^{\circ} 42'$ of S. latitude; consists chiefly of two kinds of granite, and is covered in a great measure with marshes interspersed with rocks and sand. Opposite to Cape Peron is a solitary rock of granite 150 or 200 feet high: and a large portion of the island is surrounded by lofty walls of granite, of 300

or 400 feet in height, with vast caverns penetrating into their bases. The natives of the island colour their hair from a mine of a kind of oxide of iron: and go entirely naked, except in a kangaroo skin hanging over their shoulders. Among the terrestrial mammifera, only a single species of dasyura, the size of a mouse, was seen. Numerous troops of dolphins, cetacea, and phœæ, lined the shores; the last of which are of infinite consequence in the consideration of Maria's island. Other observations confirmed the accuracy of Tasman and Captain Flinders, and pointed out a remarkable number of isthmuses proceeding from the land. Schouten's islands were all, except one, found for the first time to be so many peninsulas, connected by mountainous tracts to the main land. Few appearances more singular than this island are presented by the Australasian regions. It consists solely of lofty black mountains, divided by deep vallies; the eastern side is absolutely naked, without the smallest traces of verdure; and several parts of the summit rise into granite points, resembling so many columns raised by the hands of men. The French, next traversing the east coast of Van Diemen's Land, entered Bass's straits. There, after naming many islets, and recognising Funceaux's islands, they fixed the situation of Wilson's promontory at $39^{\circ} 10' 30''$ S. latitude. Captain Grant had made it $39^{\circ} 2'$, and Captain Flinders $38^{\circ} 57'$; but the observations which carry it $17'$ farther west, are probably nearest the truth. From Wilson's promontory on the south, to Cape Lewin on the west, is an extent of 900 leagues: the only part of which that had been surveyed previous to the arrival of the French, was from Cape Lewin to St Francis and St Peter's islands, on the eastern boundary of Nuytz' land. The English not having continued their investigation beyond Port Western, all the tract intervening between it and Nuytz' land was unknown. The French, in sailing 944 miles along the coast, from Wilson's promontory, found bays, reefs, shoals, and islands, before undiscovered. A great gulf, penetrating above 100 miles into the continent, was named *Josephine's Gulf*, and opposite to it an island 210 miles in circuit, *Deer's Island*. A vast gulf next appeared, the opening of which resembled the mouth of a large river. It penetrated above 200 miles into the land, and contained harbours and islands within its bounds. This was called *Bonaparte's Gulf*. The French then traversed a coast, by them named Napoleon's land, and in the course of their run discovered 160 islands, all very low, and of a grey, yellow, whitish, or black colour. Nearly the whole were of the most repulsive aridity; their surface was encrusted with dingy lichens; few exhibited a tree or shrub; fresh water scarcely existed in any of them; and they were entirely uninhabited. It was further ascertained, that the expectation so long entertained of a river behind the isles of St Francis and St Peter, dividing New Holland to the gulf of Carpentaria, were delusive. Forty-three days were occupied in surveying Napoleon's land; and the French affirm that, in the course of their navigation from Wilson's promontory to Cape Farewell on the west, they saw above a thousand leagues of coast, including bays and islands. But their researches were baffled by a succession of tempests: rocks and shoals threatened them on every side, and frequently interrupted the progress of investigation. At length the failure of provisions and sickness among the crew, constrained them to think of seeking relief in some port of Australasia. In May, 1802 they stood for Port Jackson, sailing round by the

south of Van Diemen's Land, instead of passing Bass's straits. Fluted Cape, they remarked, consisted of lofty reddish basaltic columns, rising 500 feet above the level of the sea, and forming an enormous causeway, against which the waves broke furiously from the south. Such basaltic appearances, both there and in other Australasian islands, were considered the more singular, as no volcanic substances were recognised in their vicinity. In Adventure bay, the rude aspect of Fluted Cape suddenly changes; a calm instead of a tumultuous sea prevails; the shores are covered with beautiful trees and shrubs; and thick forests clothe the very summits of the mountains. Meantime the scurvy made the most deplorable ravages in the vessels, and on board the Geographer there were only four men who could keep the deck: On approaching the English settlements, their manœuvres betrayed the weakness of the crew, whence the governor sent out assistance to bring them into port. Here the French made a considerable stay: one vessel was sent home, and the other, accompanied by a small bark, resumed her voyage of discovery in 1803 and 1804. Detailed accounts of this voyage have not yet reached this country; but we have reason to expect that they will prove highly interesting to men of science.

Towards the end of the year 1805, Mr Savage visited the Bay of islands in New Zealand, situated in 35° 6' S. latitude, and 174° 43' E. longitude. From his narrative we may infer, that the inhabitants, of that part at least to which his observations were chiefly directed, are in a state of civilization far superior to those in many other portions of Australasia. The principal town consists of about an hundred huts, partly on an island, partly on the main land. Each habitation on the latter is surrounded by a small patch of cultivated ground; but those on the former are occupied by the chief and his people, and are without any appearance of cultivation.

The numerous voyages between our Australasian colonies and the mother country, or the eastern settlements, are occasionally productive of discoveries in their route. These, we must regret, are not preserved, and regularly communicated to the public, from which, we are satisfied, many geographical illustrations would ensue.

An infinity of unknown objects, well deserving the attention of naturalists, are produced in the seas and on the shores of Australasia. Three new quadrupeds, all singular, and some of them far removed from those of the old world, have been discovered; the kangaroo, the wombat, and the *ornythorincus paradoxus*. The first resembles a huge rat three or four feet high; it leaps on its hind legs, or supports itself solely on the root of its tail: the second is a creature of the utmost docility, which, in its wildest state, may be seized and carried away without struggle or resistance: and in the third, nature, by a strange association, has elongated the snout of a quadruped into the bill of a bird, furnished with two real and perfect mandibles. The wombat is already domesticated, and dwells in the English cottages as tame as a dog. Numerous beautiful birds are produced in Australasia; the bird of paradise, which was so long celebrated in Europe as wanting feet; parrots, cockatoos, a singular species of cassowary inhabiting Deeres' island and the continent; and above all, the black swan, a bird which, until discovered there, was deemed of fabulous existence. Whales of

immense size, seals, and dolphins, line the shores, often appearing in such extensive shoals as to be mistaken for a reef covered with dangerous breakers. Many serpents of different species are seen floating on the surface of the sea, and an enormous cuttle-fish, rolling like a cask on the waves, stretches out its monstrous tentacula seven or eight feet in length. The mollusc tribe appears in peculiar variety and brilliance. New vegetables are found in every quarter. One marine fungus reaches from the bottom of the sea to the surface, 250 or 300 feet deep, on a single stem, which is supported in an admirable manner through its whole extent by vesicles filled with air. Detached by the violent agitation of storms, this gigantic weed floats in so great an abundance as almost to impede the navigator in advancing towards the neighbouring shores. On various islands, and also on the continent, are trees above 200 feet high, or much more according to some narratives, and seven or eight in diameter. Without entering more minutely into this part of our subject, a general idea of the novelties of Australasia may be formed, by learning that the French transmitted from Port-Jackson no less than 40,000 animals of all different classes. By their united labours, they have enriched the National Museum with above 2500 species absolutely new: and, what cannot fail to be deeply interesting to the contemplative philosopher, some animals have been found alive in these regions, which were previously known only in a fossil state.

Descending the different gradations of society, man is exhibited to us in his most savage state in Australasia. His physical constitution, the structure of his person in an enormous head and slender extremities, distinguish him from all other nations. His sight is more acute, and his hearing more perfect, but his strength is less than that of natives belonging to civilized countries. Regions so extensive and far removed are inhabited by various races of people, whose appearance, as well as manners and customs, differ according to their respective tribes. Population, however, from many reasons, is scanty; which well illustrates how much a kingdom is strengthened by civilization, and the ready means of subsistence. Savages rest their security principally on personal superiority; for the right of appeal from injury is rare. In Australasia, where supplies of food are precarious, the natives are sometimes forced to swallow large portions of a kind of soft earth to appease the cravings of hunger; and this is said to be of easy digestion. The affections of the Australasians are blunt when compared with those of the inhabitants of other countries. Parental love may be assimilated to the attachment of an animal for its young, and conjugal affection centers more in convenience than regard. Mothers not only procure abortions by violent means, but lamentable instances are told, and those too well authenticated, where, to be freed of the plights of their infants, they bury them alive: a horrible expedient, and unexampled in any other part of the world. Yet their own sufferings must infallibly tend to lessen the poignancy of feeling. The rude and brutal men tyrannize over them; they are exposed to insult and indignity; and their condition is little better than that of slaves. The union of the sexes, though apparently matrimonial, is, in many cases, only a temporary association. The courtship of the men does not consist in smiles or solicitation, but in stealing behind the object of desire, felling her to the earth with a club, and car-

rying her off while in a state of insensibility. She is kept by the man as his wife so long as he finds it convenient: he then deserts her to form a new alliance, accompanied by equal violence. The Australasians are universally to be distrusted; they are cruel, treacherous, and commonly guided by the impulse of the moment. Nothing but the consciousness of inferiority awes them into submission; and they never lose sight of that instant, when the vigilance of others may be lulled asleep. All are brave, suffer pain with fortitude, and among some tribes an injury is retaliated to the precise extent that it has been inflicted. Every sentiment of delicate reserve is unknown among these people: which amply proves that modesty is an acquired sentiment, and not implanted by the hand of nature. Investigations into the disposition of the Australasians has removed a doubt, which was only made such, because revolting to our feelings, that many tribes are cannibals. But this is now so fully ascertained, that it will never be again called in question: for the inhabitants of these regions are greedy of human flesh. Viewing the fact with a philosophic eye, perhaps it ought not to appear so strange that men can devour each other. We ought first to consider how low the Australasian rank in the chain of society: probably they are removed only one link from the brute creation. Many of their tribes are situated in bleak and barren districts: they are strangers to the art of cultivating the earth; few vegetables of natural growth are adopted for food; and animals are rarely within their reach. While prosecuting their frequent wars, they are exposed to additional privations, augmenting in proportion to the continuance of hostilities. But in devouring the bodies of their enemies, they not only gratify revenge, and possess an unequivocal token of superiority, but, by an easy means, the pressing calls of nature are satisfied. Neither ought a banquet of human flesh to appear incredible. Have we not known repeated calamitous occasions, some even of recent date, where, among our own countrymen, the survivors fed on their deceased companions merely to protract existence? nay, where the flesh of one, sacrificed to preserve the lives of others, was greedily devoured, and his warm blood drunk with pleasure.

All that we behold in Australasia, however, is not to be considered as entirely new; for there are, in the manners and customs of the natives, several conspicuous coincidences with those of the old world. In certain places they burn their dead. The origin of this custom is lost in the antiquity of those barbarous nations; but M. Peron, while speaking of the tombs which he found in Maria's island, endeavours to account for it thus. "Man is, in these regions, an absolute stranger to every principle of social organization; wanting chiefs, properly so denominated; without laws, naked, ignorant of agriculture, and deprived of the certain means of subsistence. His only arms and utensils are a rudely fashioned club and spear. Wandering with his family on the coast, where his ordinary exigencies are supplied, he remains longer, and returns more frequently to parts where shell fish abound, and where a stream of fresh water enhances the value of the situation. Does a respected old man die, leaving a numerous family, how shall they dispose of his body? They cannot abandon the corpse of a parent to beasts of prey; consequent putrescence could not fail to prove disgusting; and the scattered bones of what they knew once formed their parent, constantly presented to their sight, would

excite a painful sentiment of self reproach. They are restrained from throwing the body into the sea, a natural and easy expedient, lest it might again be cast up on the shore; and perhaps its corrupted members might be mingled with what they sought for daily food; embalming it is beyond their ideas and resources; and inhumation is so much the more difficult, from the hard and rocky soil, and from their having no utensil wherewith to dig a grave. Yet such a measure would probably be resorted to, did not one occur which is more easily executed. This is *cremation*. Here every thing conspires to the facility of execution; fire and materials are ready at command; only a few hours are required to finish the work; and the fragments of bones, which are the sole residuc, may be covered with the ashes produced. Thus the custom of burning the dead is not the pure effect of chance; it results from physical and local circumstances."

Although many Australasian regions are wild and sterile, there are extensive portions which cannot be exceeded in fertility. The beauty of different islands, the salubrity of the climate, and excellence of the soil, held forth the conspicuous advantages which would ensue from rendering them a permanent abode. Hence it was that, centuries ago, the utility of colonizing Australasia occupied the attention of Europeans. Mendana, as we have seen, established himself in Santa Cruz, an island presenting the most valuable resources to the navigators of the neighbouring seas. His views, however, were not originally directed to that particular spot; for it was only in consequence of his search for the Arsacides failing, that he went thither in 1595. When the colony was abandoned, and, on Mendana's decease, the government devolved on his widow, she made another attempt to discover the Arsacides. The voyage was short and unsuccessful, and a sudden determination was adopted to sail for the Spanish settlements in South America. Quiros, who had been chief pilot to this expedition, renewed the design of a colony, after having a second time traversed the Australasian ocean. Whether or not he carried out people and materials for such a purpose, or what was the specific intention of his voyage, is uncertain; but he addressed a memoir on the subject to Philip III. of Spain, which was published in 1610, a few years after his return. He entertained a different opinion from Mendana, with regard to the most suitable place for a settlement, judging the Tierra Austral del Espiritu Santo, lying some degrees farther south, as the best. It is not surprising that he should have felt partiality towards a territory which he himself discovered. In enumerating its qualifications, he proceeds: "Finally, sire, I can, with confidence, assert, that the bay of Vera Cruz, situated in 15° 20' south latitude, presents the greatest advantages for the foundation of a large city, and the establishment of a numerous colony. I can but imperfectly describe the riches awaiting those Europeans who shall visit such delightful countries; time, in unfolding them, will make amends for my inability; and I doubt not that this colony will become the centre of communication and future mart for all the commerce of Chili, Peru, Ternate, the Philippines, and other remote kingdoms under the dominion of your majesty." Quiros pledged himself for the success of any enterprise which should be devised for establishing a colony: and, as a more ready inducement, gave in detail a truly flattering picture of the soil, climate, beauty, and salubrity of that

and other Australasian regions. We apprehend that no active measures were ever taken to adopt his judicious proposal.

The learned President de Brosses terminates his work on southern navigations with an ingenious and enlightened disquisition on the establishment of colonies. He shews the various ways in which they may prove useful to the mother country, either serving for the deportation of criminals, or for the ends of commerce. After treating at large of the different regions, their qualities, and defects, where settlements may be made, he decides in preference of Australasia. "Any colony established in New Britain, New Guinea, New Holland, or among the Papuans, will have the clue of Ariadne at command. With time, perseverance, and some expense, which cannot be regretted, as it will return an hundred fold, all will be successively attained. This, it is true, will not be the work of a day. Great projects presume the necessity of great exertions, and these long continued. The calculation of time by years belongs to individuals, a whole nation counts only by ages. Powerful kingdoms being adapted for extensive views, their kings, animated by the love of glory, attachment to their country, and benevolence towards mankind, ought to consider their people as always in existence, and labour for an infinite protraction of time." M. de Brosses, after reviewing the state of all the countries then known, seems to think that New Guinea is the most favourable site for an Australasian colony. He enters into considerable detail concerning the persons, utensils, and materials, requisite for founding an establishment, and the advantages which might be expected to result from it. The mode to be pursued in carrying on an intercourse with the natives next engages his attention: he suggests what difficulties will be opposed by them, and recommends the utmost moderation in all the dealings of the settlers. In a work, *Terra Australis Cognita*, published ten years afterwards at Edinburgh by a Scotch advocate, the same ideas are farther insisted on: but this work being founded entirely on the former one, and possessing few claims to originality, merits no farther consideration.

We are not aware, that, from the days of De Brosses, the colonization of Australasia occupied the notice of Europeans, until necessity compelled the British government to look for some distant establishment. It had been the practice of Great Britain, during many years, to transport felons to the American plantations; but the revolt, which ended in their separation from the mother country, rendered it necessary to provide another place for a similar purpose. Most of the southern navigators had approached the coast of New Holland where it is bleak and barren, whence disadvantageous conclusions had followed concerning its nature. The discoveries of Captain Cook, however, shewed, that the eastern parts were rich in vegetable productions, that the soil was good, and the climate agreeable. Government, after having sought in vain for a suitable place on the coast of Africa to receive transported criminals, determined, in 1785 and 1786, that part of Australasia should be chosen as a settlement. In the subsequent year, several vessels laden with convicts, and also carrying out the members of a civil government, sailed for Botany Bay. They reached it in safety; and having founded a town in the vicinity, began to cultivate the country. It would exceed our design of exhibiting a brief sketch of the progress of discovery, and general views of Australasia, to follow the advancement of that colony. Thousands of

British subjects compose it, and branches on a lesser scale have been established elsewhere. A settlement originally intended for the cultivation of the flax plant, has been made on Norfolk island. More recently it was proposed to establish another at Port Philip, in Bass's Straits. The harbour there was said to be excellent, and the qualities of the neighbouring country were supposed peculiarly well adapted for it. Two ships of war and a merchantman, therefore, sailed from England in 1803, carrying out what was necessary for accomplishing this object. The civil and military departments, settlers, and convicts, were all landed on the coast, where, to judge by simple appearances, every thing promised fruitfulness and plenty. On narrower inspection, however, none of the soil nearest the shore was fit for producing esculent vegetables; and what at first sight were thought pools of fresh water, proved only drains from swamps, stagnant and deeply impregnated with the decaying remains of plants. Port Philip was on the whole considered an unsuitable situation, and the colony soon removed to Derwent river.

Doubts have lately been started concerning the expediency of retaining our present colonies in Australasia. Whatever may be their real advantage to Britain, neighbouring nations have unquestionably beheld them with surprise and admiration. Assuredly it may excite admiration, that countries altogether uninhabited, or occupied within these very few years by the rudest of all known savages, overgrown with woods, and intersected by marshes, should at this early period exhibit fertile plains covered with luxuriant harvests. That whole towns should be erected, and the communication of the different settlements be carried on through means of roads, now traversed by carriages framed in the British metropolis. That cattle, once unknown in the vast continent of New Holland, should at present run wild in greater numbers than are sufficient for the demands of a populous nation; and that sheep, equally unknown, should have seven years ago been possessed in flocks of 4000 by several of the settlers: a fact which has given rise to calculations and conjectures, that they will soon produce more wool than all Great Britain has occasion to consume. Safe and commodious harbours afford a convenient reception to vessels employed in the Australasian whale and seal fishery: and merchants have found a ready mart for their adventures in traffic from the Cape of Good Hope, or India. All this resulting in so short a time, and when opposed by obstacles unexampled in forming other establishments, ought more and more to increase our wonder that it has been attained. The French navigators express their lively astonishment at the maturity of our Australasian colonies. Let us cite the report of the Imperial Institute on the voyage of discovery submitted to their opinion. "Every where in the regions traversed by M. Peron he has found the rivals of his country. Every where have they formed the most interesting establishments, of which erroneous and imperfect ideas prevail in Europe"....."No subject can be more curious or interesting, both to the soldier and statesman, than the colony of Botany Bay, so long despised in Europe. Never was there a more conspicuous example of the omnipotence of laws and institutions over the characters of individuals. To convert the most hardened villains, the most daring robbers, into honest and peaceable citizens, or industrious agriculturists. Then to operate the like revolution in the vilest prostitutes: to change them by infallible

means to faithful wives and excellent mothers. Next to watch over the rising population; to preserve them by the most assiduous care from the contagion of their parents, and thus breed up a generation more virtuous than the race from which it sprung;—such is the impressive picture which the English colonies present." The justice of these observations we ought not to dispute; but whether the benefit derived from Australasia shall be permanent can be unfolded by time alone.

AUSTRIA.

AUSTRIA, in German *Osterreich*,* or *Ostreich*, is a considerable province of southern Germany, which has given fourteen emperors to that country, six kings to Spain, and has made a conspicuous figure in Europe for ten centuries. Of the early history of this fine region we are almost totally ignorant. Charlemagne conquered it in 791, after he had previously pushed the eastern boundary of his empire to the present frontiers of Bavaria and Austria; and, crossing the river Ens, which now divides Upper from Lower Austria on the south side of the Danube, he drove the eastern tribes, who were invading Germany, beyond the river Raab, in Hungary, and entrenched its banks as the limit of his western empire. He appointed governors, by the title of margraves, (or wardens of marches,) in the conquered country, and granted them various privileges, as protectors of the adjacent provinces against the barbarians of the East. It is probable, that the name of the principality, as well as its extent, varied during the period which elapsed from its establishment as a separate margraviate in 791, to the reign of the Emperor Otho III. who, in 996, gives it the present name in a written document still extant. The document in question, dated 1st November 996, refers to a grant of a village then called Nuiwanhova, now Waidhofen, made by the emperor to the church of Freisingen. "Nos Otho, &c. quosdam nostri juris res in regione vulgari nomine *Ostirichi*, in Marchâ et in Comitatu Hainrici comitis, filii Luitpaldi marchionis in loco Nuiwanhova dicto: id est cum eâdem carte et in proximo confinio adjacentes xxx regales hobas concessimus." *Hand Metr. Salish. cum notis Christ. Gerwoldi*. Ratisp. 1719, fol. tom. i. p. 94.

It is probable that *Oster-reich* (eastern kingdom, or principality) had for a considerable time been the vulgar name of the country, before the date of this grant, and that the vernacular language of the people was the same as it is now, since its first conquest and partial colonization by Charlemagne. Certain it is, that they have been nearly the same from 996 to the present times.

Austria continued a margraviate until 1156. During the 400 years which intervened between its establishment under that title and its exaltation to an archduchy by the Emperor Frederick I., in favour of his friend and relative Henry II. of Austria, Germany had been convulsed with wars, occasioned by claims to the succession to it. In 1156, however, the emperor just mentioned united Upper and Lower Austria (pretty much in their present extent in 1810) into one dukedom, and that too with such extensive privileges, that its bonds of dependence as a part of the fœderal Germanic body were almost totally dissolved. Henry and his successors ranked immediately after the electors, and before all the other princes and dukes of Germany. By the solemn act concluded at Ratisbon in 1156, the new dukedom was declared hereditary in Henry's family; failing of males, it was to descend to females; and, in the event of there being no direct heir of the ducal house, the actual possessor was to bequeath Austria to whom he pleased. These last mentioned privileges are very remarkable for that period of our European history.

Henry died in 1177, and was succeeded by his eldest son Leopold, who was the first hereditary duke of Austria. This prince was fortunate enough to receive from Othokar VI. duke of Stiria, that extensive province as a formal legacy. The important donation was confirmed to him by the Emperor Henry VI., who granted him the solemn investiture of that dukedom, at Worms, in 1192. But Leopold proved very ungrateful to his superior for this act of kindness. Our *Richard Lion-Heart*, on his return from the Holy Land, was shipwrecked on the coast of Istria, and attempted to make his way through Germany to England in the dress of a pilgrim. He was discovered, however, at Vienna, and, by the order of Leopold, with whom he had quarrelled at St Jean d'Acre, ungenerously cast into a dungeon, and treated with extreme inhumanity. It was a considerable time before the mediation of the emperor, and a heavy ransom, procured the liberty of the gallant Richard.†

Leopold was, in 1194, succeeded by Frederick I., who went to Palestine and obtained the surname of

* *Osterreich*, and not *Osterreich*. DU PONCEAU.

† The ruins of the castle of Thierstein, a few leagues above Vienna, where he passed many dismal hours, exhibited to us, in 1805, a sight worthy of the barbarism of its ancient master. Some French infantry took refuge among the ruins, after having been put to flight by a superior body of Russians. The latter, paying no attention to the demand for quarter made by the French, murdered the greater part of them in the ruins, and cast the rest headlong from the ramparts into the Danube.

Catholic. The younger brother, Leopold, the seventh margrave, but second duke, succeeded him, and was the first of the Austrian princes who adopted the wise policy of acquiring territory by purchase, instead of chicanery or arms. He bought from the bishop of Freisingen some extensive estates and superiorities in Carniola, which, in 1809, remained in his family. He proved himself, in many respects, to be greatly superior to most princes of his age. Many of his successors availed themselves of the same means for gaining admission into provinces, which they intended gradually to secure altogether for themselves; and they were, perhaps, as much indebted for their astonishing success to their pacific policy, as to their military talents and their good fortune. It was not, however, until 1272, when Rudolf, count of Habsburg and Kyburg, and landgrave of Upper Alsatia, (founder of the houses of Austria and Lorraine,) was elected emperor, that Austria became a formidable power. That prince, the best politician, and one of the ablest men of his age, contrived to elude the jealousy of his rivals, and to consolidate the power of his heir, while he apparently studied the advantage of all the collateral branches of his house. In order to soothe the minds of the electors, always suspicious of their emperor's destination of their property and power, he granted to his two sons the investiture of Austria, Stiria, and Carinthia, *with their dependencies*; and to Mainard, their nearest heir, Carniola, and part of Tyrol; but with the restriction of a joint investiture with his sons, and a reversion in their favour. The count of Tyrol acknowledged them also as his superior lords. All these arrangements took place at a solemn diet at Augsburg, on the 27th of December 1282.

The sudden and great elevation of a simple count of the empire to the imperial dignity, and to the power of granting investitures so important to his family, without making enemies of the other great German princes, is a singular fact in the history of the times. Rudolf certainly was not elected to establish and extend the imperial authority, but, on the contrary, because his territories and his influence were so inconsiderable as to excite no fears or jealousies in the other princes of the empire, who were willing to preserve the *forms* of a constitution, the power and usefulness of which they had destroyed. Some of his successors were placed on the imperial throne from the same motive; but none knew so well as he did how to profit by the occasion thus offered, for extending and confirming the power of his family. The partition which he made of his territories among his sons and relations was entirely illusory, and calculated merely to lull asleep the suspicions of his neighbours. By the very acts of division and investiture, he reserved to himself the power of making what changes he might think fit in the testament by which he conveyed his estate to the members of his house; and actually declared his eldest son Albert sole proprietor of his Austrian provinces, a few months after he had secured the legal confirmation of the first grant by the diet.

It was the uncommon prudence, foresight, and caution with which he steadily followed out one grand leading object, without losing sight of it for a moment, that enabled Rudolf to accomplish the projects which he had formed for the grandeur of his family, and to lay so firmly the foundations of the Austrian monarchy. Among his

other talents as a statesman, we may remark two, by which he obtained the greatest advantages; and the want of which, in his successors, has endangered or ruined their government: These are, a respect for established forms, and the opinions of his contemporaries, and a singular felicity in seizing the proper time for the execution of his purposes. He was often heard to say, "that violence *in form* was worse policy than violence *in act*;" and, "that for every human effort it could only once be said, *Dies ist die Zeit*," 'this is the proper moment.' He did every thing through the medium of the electors and great princes, whom he knew how to gain, and to attach, according to the forms and regulations of the empire, and never once began any thing too soon or too late. How different from the conduct of his successors Joseph and Francis in our own days!

Albert was declared king of the Romans in 1278; but this did not much contribute to his personal happiness, nor to his power as a sovereign. He was murdered by his own nephew John, (his brother Rudolf's son,) in 1308. His son Frederic, surnamed the Handsome, succeeded him as archduke of Austria; and his other sons, Leopold, Albert, Henry, and Otho, enjoyed considerable fortunes in consequence of their father's will. Frederic aspired at the imperial crown, and was accordingly elected by a party, while Louis of Bavaria was set up in opposition by a very powerful body of the Germanic union. A bloody battle was fought at Muhl-dorf, in 1322, between Frederic and Louis. The latter gained the day, and took his rival and his brother Henry prisoners. He imprisoned Frederic in the castle of Transnitz, and entrusted Henry to the king of Bohemia, who powerfully befriended him on this momentous occasion. Louis was, however, soon after greatly embarrassed by the intrigues and hostility of Pope John XXII., who was determined, if possible, to pull him from his throne, and, with that view, wished a reconciliation with the Austrian princes. He therefore gave liberty to Frederic to return home to his states, but under the condition of renouncing the imperial dignity, both for himself and his family, during Louis's life, and also of procuring his four brothers agreement to that condition. Here a scene of honourable and disinterested generosity opens, which is uncommon among princes in every age, and of which few traces exist in the history of the world. Frederic's brothers could not be prevailed upon to agree to the renunciation promised to Louis. The spouse and children of the Austrian monarch supplicated him to remain at home, and to consider his engagement to his rival as cancelled by the cruel treatment which he had met with during his imprisonment, as well as by the consideration that his promise of returning was extorted from him by force, and consequently void in a moral as well as in a religious sense. His brothers joined in the same entreaties, and displayed sentiments of affection very inconsistent with the ambitious projects which prevented them from accepting the alternative of renouncing all claim, during the life of Louis, to the imperial dignity. Frederic, in spite of all their entreaties, returned to Munich, his enemy's capital; delivered himself up, on the day appointed, as his prisoner; and, to the astonishment of Europe, renounced his crown, his liberty, the endearments of a family whom he tenderly loved, and every prospect that could make life valuable, for the sacred pledge which he had

given by his word. What a contrast to the conduct of the popes and princes of his age; and what a charming glimpse of moral light across the midnight darkness of the times!

Louis, deeply affected by the magnanimity of his rival, received him as his bosom friend. They swore perpetual friendship, and lived as brothers until the end of Frederick's life.

For the space of 150 years from this period, the house of Austria underwent various changes, too tedious to mention, sometimes very critical, but generally ending favourably, until, in 1496, all the provinces which had belonged to it, excepting the Swiss cantons, were united into one sovereignty, along with many other rich countries, in the person of Maximilian, emperor elect in Germany, and king of the Romans. This took place nearly 200 years after the Austrian provinces had been divided among the descendants of Rudolf of Habsburg. Maximilian married Mary, the only child of Charles the Bold, duke of Burgundy, and heiress of his valuable states in France, Flanders, and on the Rhine. By her he had a son and heir, Philip the Handsome, who espoused Joanna, daughter of Ferdinand, king of Arragon, and of Isabella, queen of Castile. This Philip was father of the celebrated Charles V., who succeeded, in 1516, to an aggregate of European power superior to that of any monarch since the death of Charlemagne. Charles V. had a younger brother, Ferdinand, and a sister, Mary, who married Louis II., king of Hungary and Bohemia. Ferdinand espoused, in his turn, Anne, sister of his brother-in-law Louis; and thus, by a double marriage, the way was paved for the annexation of Hungary and Bohemia to the Austrian states. The marriages took place at Lintz, in Upper Austria, on the 27th of May 1521.

Louis, of Hungary and Bohemia, fell in the battle of Mohatsch, in 1527, and Ferdinand contrived to get himself crowned king of Hungary and of Bohemia towards the end of that year. He, and his successors, however, have not enjoyed those two kingdoms in tranquillity since their incorporation with the Austrian provinces. They carried on, for 150 years, until the peace of Carlowitz, almost constant wars with the Turks for them; and the frontiers of Hungary, towards Turkey, were not definitely fixed until our own times.

In 1522, Charles V. yielded up to his brother Ferdinand all the German provinces, excepting the Low Countries, which he inherited in right of his grandmother, Mary of Burgundy; and thus the Austrian line was divided into two branches, the German and the Spanish. His brother procured him to be elected king of the Romans in 1530. Ferdinand died in 1564, after having added the kingdoms of Hungary and Bohemia, with Moravia, part of Silesia, and several other smaller principalities, to the Austrian empire.

The three sons of Ferdinand of Austria, viz. Maximilian, Ferdinand, and Charles, divided his dominions among them. The eldest was emperor of Germany, and archduke of Austria. The descendant of Charles, the youngest son of Ferdinand, also named Ferdinand II., reunited once more, in 1619, under his authority, almost all the provinces which were possessed by Ferdinand, his grandfather. This Ferdinand began the 30

years war against the Protestants, and carried it on during the remainder of his life. Under him served Tilly, Wallenstein, and other eminent captains, against Gustavus Adolphus and his heroic generals. He fixed it as a law in his family-succession, that all his territories should descend to one, by right of primogeniture, and soon thereafter died, in 1637.

Ferdinand III. succeeded his father, and put an end, in 1648, to the 30 years war, by the famous *Treaty of Westphalia*, which constituted, for a long time, the basis of the public law of Germany.

Leopold I. succeeded Ferdinand III. in 1657, and reigned as emperor and archduke of Austria for 48 years, till 1705.

Joseph I. ascended the throne of Germany as emperor and archduke, on the death of his father Leopold I., and, aided by our great countryman Marlborough, raised the house of Austria's power to its ancient pitch. He died in 1711, and was succeeded by his brother, who assumed the name of Charles VI. The wars which Charles carried on in Germany, Italy, and Spain, against Louis XIV., and others, made his reign conspicuous, and immortalised the talents of his principal general, Prince Eugene of Savoy. This prince commanded also against the Turks, and compelled them to sue for the peace of Passarowitz, in 1718, the most splendid and honourable which Austria had ever made. Charles VI. expired, after a turbulent reign, on the 20th of October, 1740, leaving his eldest daughter, the celebrated Maria Theresa, who was married to the young duke of Lorraine, heiress of all his possessions. In Charles was extinct the last of the family of Rudolf of Habsburg in the male line. With Maria Theresa's son, Joseph II., who was proclaimed king of the Romans in 1764, commenced the second royal house of the Austrian family, viz. the house of Lorraine. Maria Theresa, whose heroic conduct, and inconsistent and tumultuous political career, are well known, died on the 29th of November 1780, leaving her vast empire, and an army of 300,000 men, to her son Joseph, now mentioned.

Of all the princes of the house of Austria, none laboured with more sincere ardour to promote the welfare of the people than Joseph II., and yet of none was the reign so disastrous to his country. He was not always mistaken in the views which he took of the best interests of his subjects, nor perhaps in his conceptions of the means of improving their condition; but his precipitancy and rashness ultimately defeated all his projects. He wished, at the same time, to ameliorate the internal government and administration of his vast empire, and also to extend its limits; to cultivate the lands which he possessed in superfluity, and to acquire new territories; to civilize the millions of savages under his sceptre, and yet to reduce other millions under it also; and to finish every thing before it was well begun. Forgetting the example of his wise and great predecessor Rudolf of Habsburg, as well as of his illustrious contemporary Frederick of Prussia, who never studied the value of any thing so much as that of *time*.^{*} He either rushed prematurely upon enterprises which required much delicate caution to render them palatable to his people; or, on the other hand, neglected the application of means, which, if properly timed, might secure the complete

* Frederick was wont to say, when accused of hurry or impatience, "He who gains time gains every thing."

AUSTRIA.

accomplishment of his projects. He appeared, indeed, all his life not to know, that time is one of the greatest and most essential elements in human institutions; and that what may be prudent at one period, may even, among the same people, denote absolute madness at another. He pulled down churches, monasteries, and nunneries, in one part of his dominions; and overset all ancient investitures in another; while, in a third, he proved himself the determined and bitter enemy of all that savoured of innovation. In Bohemia and Hungary he favoured the Protestants, and disgusted his Catholic subjects; while in Flanders, where public opinion had made eminent advances in the career of complete civilization, refinement, and tolerance in matters of religion, he followed a very different course: thus contriving, by a singularly unfortunate species of political blundering, to alienate the affections of the great majority of his subjects, without conferring any essential benefit on the remaining part of them. To this we may add, his contempt for the feelings, or, as he called them, the prejudices of his subjects, and for what every wise prince will always treat with mildness, if not with respect, their ancient usages, customs, and superstitions. He certainly appeared in Austria a great deal too soon, and before that country was ripe for the schemes of improvement, which, in a more civilized nation, might perhaps have been practicable. Had that nation possessed a more intimate acquaintance with modern ideas, and with the literature which has been diffused over the greater part of northern Europe in our times, he would very probably have produced something among them like the French revolution. The French monarch did not prevent, or could not prevent, that tremendous explosion; but the Austrian would himself have accelerated and increased it. The acting causes of the French revolution were quite foreign to the government, and beyond its controul; in Austria, the sources of the impending change were in the government itself, and yet their results have been almost equally fatal, in the first instance, to the tranquillity and happiness of both nations. Joseph's innovations would have produced fire and fermentation in France, but they excited, at the moment, only a passive species of dislike and disgust in Austria, Hungary, and Flanders; which afterwards degenerated into a sort of apathy, and intellectual moral palsy, when the hour of trial arrived. His wars, or quarrels, with Turkey, Prussia, Bavaria, and Flanders, accordingly terminated in a manner which gave no good presage of the state of his empire as a first rate power. He died on the 20th of February 1790, in the midst of preparations against Prussia and Turkey, which promised no better consequences than his former ill concerted schemes. He left no children, and was succeeded by his brother, Leopold II., then grand duke of Tuscany.

Leopold II. had reigned as a wise man and a beneficent prince for 25 years in his interesting and happy province, when he was called to the throne of Germany and Austria. He made peace with Prussia and Turkey; was involved, probably against his inclination, in the tremendous revolutionary war, afterwards so ruinous to his house, and died on the 1st of January 1792. His son, Francis II., succeeded him, and still reigns over the provinces which are the subject of this article, as a mild, tolerant, and benevolent prince. Austria, properly so called, has lost very little of the extent

which it possessed in 996, from the period in which it gave the title of margrave to its lord, until the peace of Vienna, lately concluded in October 1791. A brief summary, however, of the circumstances which have, since January 1792, conducted to bring Austria into her present situation, may not, perhaps, be ill timed in 1810.

When the revolutionary war broke out in 1791-2, and the continental powers bordering upon France began to be alarmed by the principles which it propagated, and the serious aspect which it assumed, it was natural for Austria, as the greatest monarchy of western Europe, and in contact with the revolutionary state in many points, to adopt the most efficacious means for securing herself against it. Her councils, however, were divided in opinion; and although she preferred the alternative of war to that of remaining at peace as long as France might think fit to permit her, the exertions which she made at the commencement of it bore no proportion to her own resources, or to those of her antagonist. She had every inducement for going into the field with all her forces. No time was to be lost. France had few disciplined troops; was distracted and torn by furious factions; and regarded with horror by all the cabinets of Europe. In this situation, to strike a decisive blow at once; to annihilate the army which protected Flanders and Paris, and which was in a state of disorganization and mutiny, after the first rencounter with the Austrian regulars; to draw, without delay, all her disposable military force, and the whole of the Germanic contingents, to the frontier of that empire, and along the Austrian border, but not to advance a step farther,—was a measure equally consistent with the best interests of Austria and Germany, and with the principles of political justice, upon which the governments of Europe at the time pretended to act. This measure was also suggested by the wisest men at the court of Francis II. They were averse from taking any part in the intestine divisions of France; from interfering, in any shape, with her form of government or administration; and deprecated, in the strongest terms, the idea of attempting to dismember her by conquest, and to appropriate any part of her territory in Flanders, or elsewhere, to the Austrian empire. The measure in question would, they said, protect Germany and Flanders from French principles, as well as French violence and arms; it would have a powerful influence upon the minds of parties in France herself; it would probably compel that state to have recourse to the mediation of Austria, as a friend, for reconciling her contending factions, rather than unite those factions against her, as an invader of the French territory; and, at all events, such dignified and disinterested policy would prevent any alarms in Germany and the North, from the ulterior views of Austria. On the other hand, there was a numerous and powerful party in the Austrian cabinet, which had always recommended a very different course. They mistook the character of the French revolution from the beginning, and neither understood its principles and tendency, nor the tremendous energies which it was to call into activity. These were the men who had advised the partition of Poland, the various Turkish wars, and the frequent unhappy interferences with Bavaria, and the Swabian principalities. They were men of the old school. They scorned the idea of con-

ceding any thing to public opinion, and seemed to be persuaded, that Frenchmen would display, on seeing their country invaded by foreign ruffians, and its population partitioned among them by commissioners and land-measurers, the same apathy which disgraces the miserable slaves of the East, and had lately been experienced in Galicia and Bukowina. The successful robbery in Poland had added five millions of souls to the population of the empire, and two millions sterling annually to its resources, without costing much money, or a single regiment to Austria. Flanders, Alsatia, Lorraine, and what had once been German territory, might at first with a good grace be seized upon, and circumstances would perhaps afterwards occur, which might render other acquisitions expedient. It were desirable to arrondize the empire, and to secure for ever its western frontier: Something might be given to Prussia in the north of Germany, to keep her quiet in the interim; and England would be sufficiently rewarded for any money she might advance, or any forbearance she might practice on the occasion, by throwing into her hands some trading station or stations any where on the coast of Flanders or Holland, so as to enable her ministers to say in parliament, that they had procured a key to the storehouses and shops of the continent, and would fill them up to their entire satisfaction. This party was urged to constant importunity with the cabinet, by all the emigrants from France and the Low Countries, who had flocked to Vienna after the detention of Louis XVI. at Varennes. These were joined by such Austrian subjects as had property in the Netherlands, and also by all those who expected promotion in the territories to be acquired, or in consequence of their influence at court.

The man who imagines that this party, however numerous and strong, possessed vigour, resolution, or talents, in any degree competent to the task of directing the execution of the measures which they advised, would be speedily undeceived by a few hours conference with them in Vienna. They in general exhibited nothing of the warlike politician, excepting his credulity and presumption. To the completest ignorance of the state of their enemies resources and preparations, they added the most shameful negligence in calculating and improving their own. They were, however, the ruling party, and soon acquired the absolute disposal of the Austrian revenues, and the Austrian armies. The war was to be carried on with all possible energy. An army of 364,000 men stood ready at their nod. Prussia was to co-operate. The German contingents, amounting to 80,000 men, were to join on the Rhine. Holland was to give what aid she could in men and money. England was expected to join either voluntarily, or to be compelled by her own interest and her dread of intestine confusion, to make common cause against France. Russia kept aloof, but it was impossible that she should not rejoice in the destruction of any European monarchy of the first order, which should adopt republican principles, so hostile to the maxims by which she was governed, and so opposite to her late exhibitions in Poland. At the same time, the powers, or at least the cabinets, of the south of Europe, were as little disposed as those of the north, to interfere with any military operations which Austria might carry on against revolutionary France.

Such was the state of Austria relatively to the pow-

ers of Europe, and to the two parties which divided her own councils in 1792. The war party prevailed. Austria sent nearly 80,000 men into the Low Countries. She ought to have sent three times that number, and she might easily have done it, as she had no other frontier to defend. This force did nothing; for it was commanded by men who durst not take possession of a village, or pull down a mill or a tree without an estafette from the Aulic Council at Vienna. The same council manifested equal niggardliness in furnishing supplies to the army, as it did jealousy against its superior officers. In short, no war was ever carried on with less energy than this, upon which every prudent man in the empire perceived that the fate of Flanders and Germany, and perhaps that of the Austrian empire itself, would ultimately depend. A British army was sent in 1793 to co-operate with the Austrians in Flanders. The combined armies took the strong fortress of Valenciennes, and in an evil hour, in the name of the *Emperor of Germany*, not of Louis of France, or the legitimate head of the French nation. The Austrian army when joined by the British, relaxed, as usual, in its operations! the British army was of course unsuccessful. Every thing went wrong. The English, as is always the case when they land near France, were compelled to abandon the continent and return home, after losing two-thirds of their army. Holland was conquered; the Austrians driven over the Rhine; all Flanders, and the German principalities on the left bank of that river, annexed to France; and two French armies advanced into the heart of Germany, and even to the borders of Austria. Nor was this all: Italy was lost. Bonaparte took Mantua, after having destroyed three or four armies, which had been sent by the Aulic Council in numbers exactly suited to their enemy's convenience, one after the other at regular intervals, so as to allow that general to devour them piece-meal without fighting any great battles, or putting the French Directory to any serious expense in recruiting an army at the distance of 600 miles from the French frontier. The same method was followed even after the Archduke Charles was sent to command the remains of the Austrian army in Italy early in 1797; and, indeed, has been the curse of that country's politics until the present day.

The treaty of Leoben, or peace of Campo Formio, as it is called by most writers, was the result of Bonaparte's successes against the Archduke, and put a period, for two years, to the most sanguinary war carried on in modern times. By this treaty, concluded with an enemy who was within eighty miles of Vienna, but had only 35,000 fighting men fit for action in his army at the time, Austria lost the Netherlands and Lombardy, and in Germany all her provinces on the left bank of the Rhine. For these, however, she received Venice and her dependencies from France. She therefore lost, upon the whole, only a population of about 1,200,000 souls, and very little of her real resources and strength. That such were the ideas of the Austrians themselves, appears from a monument erected on the occasion of concluding this treaty, by an Austrian nobleman in the place where the conferences were held: In a small garden, half a mile to the north-east of Leoben in Stiria, belonging to Baron Von Eckenwald, stands to this day, (at least it stood in the summer of 1808) a quadrangular obelisk, with four marble slabs on its faces and sides, containing the following words, viz.

First Face.

*Paci

Opposite Side.

*Comitum de Gallo et Meerfeldt
a Majestate
Delegatorum fœcialium
Opera.*

This inscription, ordered by Austrian officers of rank and influence, would not have been permitted to stand for eleven or twelve years, most of them past in rancorous wars between the two countries, if Austria had considered herself at that time so much humbled by the peace of Leoben; and yet she certainly was both injured and degraded by it in reality. The territory of Venice, which she took in exchange, or as an indemnification for the Netherlands and for Lombardy, was not an equivalent for what she renounced; and even if it were, it was not honourable to take what the other contracting party had no right to bestow. The consequences were what might have been expected. Venice was discontented, turbulent, and unproductive. She yielded very little towards recruiting the armies, or replenishing the exhausted treasury of her new mistress. Austria had, for the first time, since the Turkish war of 1683, seen an enemy in the heart of her hereditary estates, and permitted him not only to escape with impunity, but also to levy heavy contributions, and to dictate peace within three days march of Vienna.

Such a peace as that of Leoben could not therefore prove permanent, unless Austria had been reduced to a state of absolute nullity or insensibility, or France had granted further concessions than the plundered, insulted, and degraded Venetian states. Russia was soon called upon, both by the Emperor of Germany and by England, to join in a new war. Turkey was now also an ally against France, on account of the invasion of Egypt. An English army was sent, as before, to the Low Countries, under the command of the duke of York, and there joined by a considerable Russian force. A strong Russian army entered the Austrian states, and made some stay in the neighbourhood of Vienna previously to its march under the celebrated Suwarrow to Italy.

Bonaparte was in Egypt, wasting the flower of the French army. Discord and imbecility filled the Parisian councils. Austria once more raised all her standards, and the court party at Vienna looked forward for victory and triumph.

The bravery of the combined armies of Austria and Russia, and the military talents of Suwarrow, obtained at first some successes for the new coalition; but they proved of little consequence in the course of the war. Russians, like English soldiers, may fight like lions, and indeed often exhibit rare degrees of intrepidity and valour on the day of battle, but they do not carry on war so well as the French, nor are they so well officered, and so well supplied with the numerous requisites for long field service as that ingenious and active people. The Emperor of Russia, impatient of the sacrifices which he was making in the west of Europe, while all his exertions were necessary on the Persian frontiers; disgusted with the miserable fate of the gallant army which he had sent to Holland, and which partook in the hardships and humiliations of their brave English allies under the British commander in chief, recalled all his forces from the contest. England was compelled to remove her troops from the continent as heretofore; but she galled her enemy in Egypt, and had lately inflicted a deep wound upon his navy and army by the brilliant victory of Nelson over Brueys at Aboukir, and by Sir Sidney Smith's repulse of Bonaparte at St Jean D'Acre.

In spite of the defection of Russia and England in Europe, in spite of deranged finances, an empty treasury, bad seasons, and aggravated calamities of various kinds; notwithstanding the very equivocal conduct of Prussia, which seemed to watch an opportunity for raising herself upon the ruins of Austria: and notwithstanding the disasters of Marengo, and the loss of all Italy; Austria struggled forward, under all the vices of her old corrupted and incompetent war administration, until the decisive battle of Hohenlinden, in December 1800.

After the victory of Hohenlinden, the French general Moreau might certainly have advanced without much danger to Vienna, and dictated what terms he pleased to the Austrian monarch. But it was not the policy of France to ruin Austria, or to elevate Prussia or Russia into dangerous powers by her destruction. It was more prudent to keep her as a balance against both, until the season should arrive of degrading all the three successively, and in a way in which France alone would be the gainer, and would have to contend with only one of them at a time. The treaty of Luneville was accordingly concluded, and Austria lost only Venice, and a few trilling prerogatives in Swabia; while she got Salzburg and Berchtolsgraden as an indemnification for her sacrifices in Italy. The people of Vienna were highly pleased with these conditions; for they had expected to see the French armies in their streets, and they were glad at all events to procure any thing at that time like an honourable peace.

The Austrian armies were reduced to a lower pitch at the period of the peace of Luneville, than at any other since the year 1792, when the revolution was commenced. They perhaps exceeded 100,000 men, but the emperor could not bring 40,000 effective soldiers to bear upon any single point. To raise the military force to its usual level was therefore indispensably requisite; and this seems to have been the main object of the cabinet in 1801, 1802, 1803, and 1804. Recruiting went on with

considerable spirit, notwithstanding the loss of some important recruiting stations in Germany; and some few alterations, deemed judicious even by the enemies of the court, took place in the appointment of officers, and in the mode of paying the army. France did not look on with indifference. She always kept a vigilant eye towards the Austrian eagle, and was determined to pare his talons, or clip his wings, before he should once more soar to his ancient eminence. She therefore made one encroachment after another in Italy and Germany, and preferred so many demands, that Austria resolved for the third time to try her fortune against her great rival. England and Russia joined her with alacrity. The former gave money, promised troops, and probably meant to perform her promises in good time. The latter promised an army of 100,000 men, and actually sent 60,000 excellent troops on the day appointed, and forwarded the remainder with all possible speed. The king of Prussia was understood to be at least favourably disposed, if not actually pledged by his word and honour to join the coalition; and Sweden was to exert herself to the utmost in the same cause. Early in September 1805, the armies took the field. A court cabal sent the Archduke Charles and John, in whom the army had the greatest confidence, with secondary commands to Italy; while the post of honour, that of commanding the German army against the emperor of the French in person, was conferred upon General Mack. To complete the absurdity, this general's hands were tied up. He was ordered to advance far into Bavaria, and even to occupy the line of the Iller, 500 miles beyond the Austrian frontier, before a single Russian soldier had entered Germany. Mack's army did not exceed 80,000 men. Bonaparte was approaching with his wonted celerity, at the head of 180,000 combatants. The Bavarians and Wirtemberg troops joined him with all speed, and his army on the first week of October amounted to 220,000 effective men. General Mack sent dispatch after dispatch, and courier after courier, to Vienna, desiring permission either to retire upon the Russian armies, which were rapidly advancing, and had promised to be in Braunau on the 19th of October, or to file off towards Italy, and compel Bonaparte to meet him there by the way of Switzerland, or to risk being placed between him and the Russians, should the French venture to penetrate into the hereditary states. The unfortunate Mack, who is much more blamed than he deserves to be, was ordered to await the Russians on the Iller; and was favoured by the council at Vienna with the pleasing intelligence, that the French could not reach him before the end of October, and that in the mean time a landing, to be made by a powerful English army on the coast of France or Holland, would relieve him from more than one half of their forces. While these puerilities passed, the terrible armies of France rushed like a torrent upon Swabia, Franconia, and Bavaria. Disregarding the neutrality of Prussia, they traversed Anspach, annihilated the army of General Mack at Ulm, and on the 15th of October, the third day after firing the first shot, decided the fate of this war, and ruined the third coalition, which had for its professed object the deliverance of Europe.

It was now in vain that the brave Archduke Charles defeated Massena with the French Italian army at Caldiero, and that the Emperor of Russia put himself at the head of his auxiliary force for the salvation of Austria. It was in vain that Nelson got the brilliant vic-

tory of Trafalgar. Prussia would not stir; and England, as on many other occasions, sent her gallant troops to fight against the storms of the north sea, and the winters of Germany, long after any thing they might achieve could possibly avail herself or her allies. One day after another, Bonaparte entered Vienna; and on the 19th of the same day, with infinite pleasure, he captured the Tabor-bridge, which the Archduke Charles had left behind him, as he had pointedly left the Archduke Charles's army; and in a very few days he had entered the city, and disgraced the Emperor's army at Austerlitz.

General Mack, however, was not Austria's since the commencement of the war. In fighting this battle, the Archduke Charles, who was at the head of a very brave army of 90,000 men, within six days advanced the French, and rapidly advancing to put Bonaparte between two hills, at the very time when the action, so fatal to Austria, was resolved upon. He accordingly entered Neustadt, took the military chest of the French army there, within 50 miles of Vienna, on the 10th of December. It was too late. The field of Austerlitz had produced, on the 2d of that month, an armistice, which, on the 4th, consummated the shame of Russia, and the degradation and political death of the Austrian monarch.

By the treaty of Presburg, which was signed six months after the commencement of hostilities, Austria lost, besides other provinces, her right arm of defence, Tyrol and the Swabian principalities. These might be considered as a vast fortress towards Italy, Germany, and France. They had been, for 500 years, constituent parts of the monarchy; and their population, brave magnanimous, and warlike, had been for ages conspicuous for their attachment to the house of Austria. Their country had long been deemed impregnable, and, indeed, might justly be so reckoned, when backed by the resources of a powerful empire. Francis II. also lost Dalmatia, Istria, Frioul, and Cattaro; and, in short, cut himself off from every prospect of becoming the head of a maritime power in the Mediterranean.

In return for these sacrifices, and for heavy contributions paid in specie to the French armies, he received for his brother, the late elector of Salzburg, the bishopric of Wurtzburg, with its dependencies, and annexed Salzburg and Berchtolsgaden, which his brother had enjoyed since the treaty of Luneville to the Austrian crown.

The treaty of Presburg was the most humiliating and disastrous to which Francis had hitherto been obliged to submit. It was talked of at Vienna in a style rather inconsistent with the apathy usually manifested on such matters by the public. Many persons spoke their minds freely against it; and the best friends of government seemed to be ashamed of the condition to which a powerful empire had so suddenly been reduced. The same feeling pervaded the court, and all the princes of the imperial family; especially the archdukes, who had shared in the campaign in Italy, and who attributed wholly to mismanagement the reverses which had produced this scandalous and disastrous peace. Meanwhile, however, the finances had gone into the most alarming disorder. The florin in paper had fallen, between the breaking out of the war and the signing of the peace, from 2s. sterling to 1s. 2d., and specie of every sort had totally disappeared. The armies were destitute of all

supplies. Hungary had manifested symptoms, if not of disaffection, yet, at least, of lukewarmness towards the emperor, and had not exerted herself, during the war, in any degree proportionable to her resources. Officers in high situations had proved unworthy of their trust, and were to be tried. The arsenals of the empire were empty. Every necessary for carrying on the war was scarce, and extravagantly dear. Nothing could be expected from Prussia or Russia. Repose became indispensably necessary.

In 1806 and 1807, France occupied the period of Austrian palsy, occasioned by the war of 1805 and the treaty of Presburg, in destroying Prussia, and humbling Russia. It is foreign from our purpose to dwell upon the phrensy of those powers, who timed their exertions precisely in a way to accommodate their enemy, and to ruin their own resources. When Russia, in particular, which had on foot 435,000 men in her European states, chose to meet the French armies, upon her own frontier, with only 78,000 men, (as appears from her own statements of the battles of Pultusk and Eylau,) and when, after the enemy had spent many months inactive in her neighbourhood, she did not call forth above 40,000 men to recruit her wasted forces, and to enable her to drive him back from her dominions; Austria plainly saw, that there must have been some radical defect, some ruinous and irretrievable evil in the Russian councils, which would speedily lay that country, as well as Prussia, prostrate at the feet of France. Any exertions which she might make were therefore considered as inexpedient and unavailing, and were accordingly withheld.

The summer of 1808 exhibited to Europe and the world a new scene in the modern revolutionary tragedy. France trampled upon Spain, and Spain struggled to resist the indignity, and make it recoil upon its authors. A nation, and not merely a cabinet as heretofore, appeared to start up with an astonishing degree of unanimity, and in language unknown for ages, to assert her rights, which had been perfidiously violated. Her enemy and oppressor poured his myriads of disciplined veterans into her territory; but although generally successful in the field, these afforded a proof, by the tardiness of their advances, and the precautions which they observed, that there is a vast difference betwixt carrying on war against the cabinet of a country, assisted by its military establishment alone, and waging it with the opinions, the patriotism, the living principle, hearts, and souls of its inhabitants.

During the period which elapsed from the surrender of the French fleet at Cadiz to the Spaniards, in June 1808, and of Dupont's army to the Spanish troops under Castanos in July, and the publication of Don Pedro Cevallos' statement of what had taken place at Bayonne between Bonaparte and the family of Spain, Austria was preparing herself for some further attempts to recover her lost provinces, or, at least, to escape from the further demands of France, which seem to have been incessantly galling and unwarrantable. The troops of France were now occupied in Spain in considerable numbers. Prussia, though prostrate, must have felt her degradation, and sighed for release and vengeance. Russia, it was thought, could not always remain in a state of unnatural and pernicious thraldom. Britain was making great exertions to annoy the emperor, and might perhaps, by experience, become expert in building herself of her immense resources by sea and land. Germany was impatient under the French yoke, and so

was Italy, Switzerland, and Holland. A fairer prospect never opened upon Austria for retrieving her recent losses, and recovering the military pre-eminence which she had long maintained.

The fourth war with France, since 1792, therefore commenced. The Archduke Charles put himself at the head of the whole Austrian army, with more extensive powers than had been enjoyed by any commander since the days of Tilly and Wallenstein. He advanced into the heart of Bavaria. Bonaparte, who, on the first surmise of an Austrian war, had left Spain, and flown with his usual rapidity to the armies which stood nearest to the most formidable antagonist, soon collected on the Danube the whole of his forces in Upper Germany; and, after a series of bloody battles, compelled the archduke to take up a position in Bohemia, and the remainder of the Austrian army to retire upon the hereditary states. After a short campaign, unparalleled for the exertions made by both parties, as well as the obstinate valour displayed in every battle fought during its continuance, the fatal approach of a Russian army, and a declaration from its master, "that he made common cause with his ally France," obliged the archduke to recall his brother John from Italy, and to detach part of the main army into Poland and the North. These steps led to the battle of Wagram, and to the armistice and treaty which soon followed, and which have left the Austrian empire in its present state.

Trieste with its territory, Fiume and the Croatian Littoral, part of Carinthia, almost all Carniola, a small part of Upper Austria, with Salzburg and Berchtesgaden, and a very extensive tract in Galicia, were torn from Austria by this treaty. She is now totally excluded from the sea, and from direct communication with England, as well as all other countries, excepting the conterminous states. Her trade must suffer considerably, and her manufactures will depend in a great measure upon the pleasure of her neighbours.

She is still indeed a power of high consideration, but she can no longer be deemed independent. As long as Russia and France join against the liberties of Europe, it will be in vain for Austria to attempt any resistance. Germany, although, if united, the only nation on the continent able to cope with France, cannot, in its present state, be expected to take part with Austria. The last mentioned has long been regarded by the rest of the empire with a jealous eye. This jealousy has not as yet been quite extinguished by the reverses which Austria has undergone during the long revolutionary wars, of which we have now attempted a rapid sketch. It still actuates the southern provinces, and that too with the same acrimony as it always did the cabinets of Dresden and Berlin.

The degraded state of the princes who at present divide Germany among them, does not permit us to expect any speedy change for the better. A population of 36 millions, however, who speak the same language, and exceed the general mass of European nations in civilization and refinement, as well as in resources and military discipline, cannot always remain sunk in slavery to a foreign power. But whether that nation shall effect its own emancipation by the exertions of its princes and warriors, who may wish to re-establish the ancient order of things; or by a violent revolution, like that which wrought such wonders in France, renovate their political existence; or by what other means it may be accomplished, it would be now hazardous to conjecture.

ture. The philanthropist, however, hopes, with fond enthusiasm, to see the blessings of freedom and independence conferred on so respectable a nation; and, amidst the present distractions and horrors in which they are involved, anticipates, with pleasing emotions, the grandeur and happiness which they are destined to attain in some future and more fortunate age.

What effects the recent changes, and the matrimonial connection with the French monarch, may produce on the state of this empire, we cannot pretend to foretell. Many salutary consequences, in the interim, may be expected.* The greatest is, that the monarchy preserves its integrity: for it is not probable that Austria shall undergo any further dilapidations during the continuance of the present alliance with France; nor is it the interest of Europe that she should. Some years of peace are necessary for re-establishing her public credit, and for restoring to her paper-money the value to which the vast resources of this empire, and the good faith of the government, unquestionably entitle it. Such years she is now in a fair way of enjoying; and such repose is a great blessing after a long series of disastrous wars.

Russia will not soon be in a condition to give her any alarm. Prussia is levelled with the dust. Bavaria will probably receive no more augmentations of territory at the expense of Austria. Turkey will be fortunate, if she preserves her own dominions entire. No enemy then threatens to disturb the tranquillity of Austria in her present political attitude: And we may therefore be permitted to hope, that she shall one day recover the rank which she formerly maintained in the scale of our great European powers; that she shall adopt such military and œconomical arrangements as correspond with her immense national resources; and that she shall, sooner or later, prove an useful ally of our country, in checking the usurpations and restraining the ambition of France.

Austria Upper and Lower, (*ob der Ens, und unter der Ens.*) lies in latitude $47^{\circ} 20'$ — $48^{\circ} 57'$ north, and in longitude $13^{\circ} 50'$ — $17^{\circ} 2'$ east of Greenwich. The whole province above and below the Ens, and on each bank of the Danube, is about 140 English miles long, and at an average 70 broad, containing 9800 English square miles, or 6,172,000 statute acres, almost one eighth of the British island. One-third of this extent consists of mountains, forests, lakes, summer grazings, and pasture; and two-thirds of meadows, corn-fields, vineyards, and the scites of cities, villages, churches, and country houses, &c.

Austria is bounded by Bavaria on the west, Stiria on the south, Hungary on the east, and Bohemia and Moravia on the north. It lies almost in the centre of our European population, nearly at the same distance from Madrid and Petersburg, London and Constantinople.

The soil of Upper Austria, especially on the banks of the Danube, and of the larger streams which run into that river, is either a clayey loam, or the deposition of schistus and calcareous rocks, which are hurried down by the torrents from the mountains. In the higher valleys the soil is thinner and lighter, but very sharp and fertile, and upon the whole well adapted to corn and grass husbandry. The climate is there too precarious and boisterous for the cultivation of the vine.

The surface of the whole province is a gradual slope from the southern mountains and northern hills towards the Danube, which flows through the heart of the country, and receives every river or stream that pervades it. These rivers run into their majestic receptacle nearly at right angles from both sides, like the ribs into the keel of a ship; and indeed the general surface of Austria bears no small resemblance to the inside bottom of a ship, supposing the ribs to descend gradually and gently, and to be much less strait at a distance from the keel than near to it. The traveller, accordingly, who walks nearly along the banks of the Danube, can see more of the country on each hand, whether he ascend or descend the river, than he can from the banks of any stream of any other region with which we are acquainted. This declivity, which is uniform and gradual for many leagues on each bank, gently facilitates the draining of the ground, and the carriage of bulky commodities from the interior of the province to the markets and places of resort on the river. The ground is accordingly well cultivated, and yields a rich and beautiful prospect. The numerous towns and villages on the Danube; the variegated and majestic woods which skirt the hills that gradually rise on either hand; the monasteries, castles, spires, farm houses, and villages, here and there peeping out from the trees; the roads crowded with carriages, travellers, soldiers, &c.; and the river with swiftly-sliding barks now and then appearing and disappearing amidst its wooded islands; the whole scene crowned by a fantastically varied range of distant mountains, frequently re-echoing the solemn peals of church bells or of martial music; all these strike every stranger who visits Austria, in a degree proportioned indeed to their natural effect, but inconceivably heightened both by the unexpectedness of the apparition itself, for which he is never prepared by reading of it in the works of travellers, and by the *bon-homme* of the natives, and the universal happiness which smiles around.

The most remarkable mountain in Lower Austria is Schneeberg (snowy mountain), which is distinctly seen from the ramparts of all elevated points of Vienna every clear day. Its height is not very considerable when compared with that of many other mountains pertaining to the range of which it forms a part, being only 5200 English feet above the Danube at Vienna, or 6000 above the level of the Mediterranean; but being insulated, almost always covered with snow near the summit, and of a beautiful and majestic contour, it strikes a stranger more than any other mountain in the duchy.

The points, however, from which the traveller, who loves magnificence in natural scenery, ought to take a view of the Austrian mountains, are the following.

1. The bridge over the Trasen, a little to the eastward of the town of St Polten, nearly thirty English miles to the west of Vienna.

2. The rampart, or what is so called, of the town of Ens, a little to the north-east of the square, or market-place.

3. The summit of a pretty high hill, which rises from the eastern bank of the Gmunden Lake, about four miles to the southward of the beautiful and romantic town of Gmunden, in Upper Austria.

It is impossible to conceive any thing finer in moun-

* *Bella gerant alii, Tu, felix Austria, nunc.*

rain scenery than these points exhibit. They defy the power of language to do them justice.

The lake of Gmunden, just mentioned, with the fine river Traun running through it, and the two charming towns of Gmunden and Ebsdorf at each end, about twelve miles distant from one another, is much frequented by Austrian travellers, both by reason of the scenery of its banks, which is variegated and strikingly picturesque, and also on account of the salt springs and salt manufactures, which are found there. From this lake and its vicinity, Austria is supplied with salt to the value of 400,000 pounds *per annum*. The Wolfgang, the Aber, the Hallstatter, and many other lakes of inferior note, are the boast of the Upper Austrians, and unquestionably afford as fine and varied landscapes as any in Germany. They all abound in trout, (there called *forellen*) pike, (*hecht*), and a variety of other fishes, of which the natives are excessively fond; and they greatly facilitate the carriage of wood to the salt pans, and of all sorts of commodities to the numerous population which dwells along their shores. Let not the traveller who visits them and Upper Austria, trust to any map of this country hitherto published, not even to Kindelein's, who pretends to have drawn his from actual observation and real survey. They are all absurdly wrong and false, and will infallibly mislead any one who depends upon them. The best map is Chauchard's, and yet it is also extremely deficient with regard to this rarely frequented, and yet interesting, portion of Germany.

Besides the Danube, which rolls in great and rapid majesty through the heart of the whole duchy, several other rivers of considerable size, and which would be called large in Britain, enrich and adorn the Austrian circle. Of these the principal run from the southward, such as the Traun, the Ens, Ips, Trasen, &c. and are studded with rich and flourishing towns or villages on their banks. Wooden bridges are generally used, but they are well contrived, strongly built, and perfectly safe. Vast quantities of timber are floated down these rivers annually from the higher country forests, for fuel to the inhabitants of the champaign districts. The carriage and preparation of this fuel yields employment during winter and spring to one fourth of the population. The Austrian rivers vary greatly in colour, not only from one another, according to the nature of the channels in which they run, but also from themselves at different seasons of the year. The Danube alone retains a yellow colour all the year round. No green can be more lively or beautiful than the waters of the Traun and Ens, until they begin to be affected by the autumnal rains. Near their sources, amidst high mountains, of from six to seven thousand feet above the level of the Danube, their waters are always green, and impregnated with fine particles of schistose and calcareous sand, which are supposed, in those exalted regions, to produce the swellings of the glands of the neck, which are here so common, and in Switzerland, as well as in Austria, are called *kropffe*, in France *goures*. We met with some families in the higher vallies, who observed the constant custom of boiling the water, and allowing it to subside and to deposit this sand for many hours before they drank of it. This precaution they alledge to be perfectly necessary, and also effectual in preventing the swelling and deformity in question.

The most common sort of wood is the alpine pine, which almost exclusively occupies the sides and elevated slopes of the mountains. This the natives call *nadelholz* (*needle-wood*), which constitute a considerable portion of their fuel, and of the materials of their bridges. Ash, oak, elm, larch-tree, and most of our common forest trees, grow luxuriantly, and afford a delightful variety to their woodland scenes.

However striking to a stranger, especially if he goes from our part of the British island, the quantity of wood may be, which he sees in Austria, yet he will every where meet with grievous complaints of its decline, and the most dismal forebodings of the fatal consequences which must follow it. Certain it is, that the price of wood has risen nearly 80 *per cent.* during the last six years, even making allowances for the depreciation of the paper currency, and the great difference which now subsists between the real and the nominal value of the circulating medium of the country. The same danger from scarcity of fuel, and of wood for other purposes, is apprehended all over the west of Europe; and we every where hear the same alarming invectives against the improvidence of present occupants, and the mismanagement of their rulers.

The climate varies greatly from the mountainous frontiers of Stiria and Bohemia, to the lower borders of Hungary and the banks of the Danube. In the former, the cold is in winter intense and persevering; storms and rains frequent, violent, and destructive; the summer is usually short and precarious; and the hopes of the husbandman are often blasted by frosts and tempests in the autumnal months. The average quantity of rain that falls at the towns of Gmunden and Hallstadt in Upper Austria, which are encompassed by mountains, and lie on lakes which give them their names, is 38—46 inches, while the quantity which falls at Vienna rarely exceeds 28. The medium temperature of springs in the high country is 42°, that of springs on the Danube 44°—46°. In these mountainous regions, the winter sets in with considerable severity about the end of October; and the ground is for the most part covered with snow until the middle of March. Partial thaws, indeed, sometimes occur, but they are of short duration, and do more harm than good. Very little can be done in the fields before the latter end of March, when the regular thaw commences, and vegetation is re-established in beauty and strength. The transitions from cold to heat, and *vice versa*, are sometimes very rapid and injurious to the human constitution, as well as to vegetation and to animals; but upon the whole, this fine province cannot be deemed unhealthy or unfavourable to longevity. The most frequent instances of advanced old age which we met with, occurred, not as in Norway and Scotland, among the higher regions of the country, but in the deep and sheltered vallies.* Near the salt pans of the provinces, the race of men is slender, pale, emaciated, and feeble in body, as well as to all appearance weak in capacity and intellect. Whether this proceeds from the atmosphere which they constantly inhale being impregnated with impure salts and charcoal, so as to affect their lungs too powerfully, or from the nature of their occupations, which requires their being almost continually wet from head to foot, or from whatsoever causes it may arise, is much disputed, but the fact is undeniable. The most com-

* There appeared few instances of great longevity between 1796 and 1806, and only three, and these doubtful, of 95, 97, and 100 years.

mon diseases in those parts of Austria are pulmonary complaints, typhus and intermitting fevers, colds, rheumatisms, and epidemical distempers brought from Italy and Turkey. Southerly and south-westerly winds are the strongest. These blow from the Stirian, Carinthian, and Tyrolian Alps, over a snowy region of several hundred miles in extent. Northerly winds are the pleasantest, easterly the most piercing and durable.

On the banks of the Danube, and in the lower country, however, the heat is excessive in the months of July, August, and September; Fahrenheit's thermometer standing frequently in the shade at 95—98 degrees. On the 25th of August 1805, it was at 97°, and at three in the morning of the 26th it sunk to 54°; so rapid even in the warm months is the transition from heat to cold in this country. Tempestuous winds seldom amoy the lower districts, and the climate is as favourable for animals, for grass, corn, wood, and even some species of wines, as any part of Europe in the same latitude. Lintz, the most westerly city of Austria on the Danube, is said to be 1000 feet above the level of the Black Sea; and Hainburg near Presburg, the most easterly, is about 780 feet above the same level.

Population in 1806—1809.

Lower Austria	1,062,000	Males	. . .	817,230
Upper	. . . 646,000	Females	. . .	875,194
		Strangers	. . .	17,576
Total	. . . 1,708,000			1,708,000

There were 14,564 marriages, 65,139 births, and 66,023 deaths.* The number of families was 360,555, which gives nearly $4\frac{2}{3}$ to each family. There were 3997 nobles, and 4480 clergymen. The cities amounted to 51, towns to 333, villages to 10,728, and the houses to 249,614.

The population of the most considerable places was as follows, viz.

In Lower Austria.

	Inhabitants.	Houses.
Vienna	256,000	6318
Krems	7,000	620
Wiener Neustadt	5,000	550
Waidhofen	4,300	535
Kloster Neuburg	3,026	456
St Polten	2,960	410
Korn Neuburg	2,500	370
Baaden	2,000	270

In Upper Austria.

	Inhabitants.	Houses.
Lintz, or Lintz	17,900	1006
Ens	4,400	540
Freystadt	4,000	460
Wells	3,500	376
Gmunden	3,000	310
Reid	3,000	299
Hallstadt	2,800	281
Steyer	2,200	370

From the Tables which we have seen, it appears, that the population of Austria has been rather increasing for the last 30 years, in spite of the bloody wars which she has carried on during that eventful period. This must, in some measure, be ascribed to the influx of foreigners

from her distant provinces to Vienna, as well as to the numerous public academies and other literary and military establishments which that capital contains. Vast numbers of Bohemians, Moravians, Stirians, and Italians, are found among the common labouring and manufacturing classes in Vienna, who, although they banish none of the native Austrians, or perhaps greatly add to the population which that metropolis would at all events contain, yet greatly augment that of the province, by keeping in the country, and in its towns, persons who would otherwise flock for employment and high wages to Vienna.

The Roman Catholic is the established religion of Austria; but since the reign of Joseph II. Protestants of every description, as well as Jews, Greeks, Russians, and Turks, and in short persons of every persuasion, enjoy full toleration and security. We found a respectable Lutheran and Presbyterian chapel in Vienna, and in Upper Austria there are many thousand Protestants, who have their regular stated clergymen preaching to them in full freedom, and discharging their ministerial and clerical functions as much at their ease as if they were in England. There are indeed in Austria eleven Protestant parochial charges or parishes, the incumbents of which enjoy competent salaries from their flocks, and are much respected by their Roman Catholic neighbours. So far indeed were we from meeting with any of the intolerance and bigotry, of which we read the most exaggerated accounts in books of travels, that, although occasionally residing for years in this province since 1796, not a single instance of any thing approaching to persecution or intolerance occurred in our experience. The Austrian is indeed attached to his own religious ceremonies, and wishes them to be treated with respect and decency by others; but he never interferes improperly, nor displays any symptoms of arrogance or fanaticism. The pilgrimages which take place to Marizell, and other celebrated cells in Austria, are indeed often extremely ridiculous, and accompanied by scenes which excite much mirth among strangers: but to those who have seen the superstitions of the East, or the buffooneries and absurdities of Italy, Spain, and Portugal, they will appear to approach rather to innocent recreations, than to degrade the persons concerned in them from that rank as reasonable beings, with which the gross fooleries of superstition are frequently incompatible. Neither the Austrian clergy, nor the teachers of youth, are responsible for the remains of ancient and traditional customs, to which their people still cling with fond enthusiasm; nor can we impute to them any more collusion in misleading them, or suffering them to be misled, than we can to our own Highland clergy and schoolmasters for permitting a belief in witchcraft and the second sight.

The best proof of the efficacy of religion is to be deduced from the morals of a people. No nation in Europe is less stained with public crimes than the Austrian. In none do we find fewer vices, less disorder, and more good nature, kindness, charity, and genuine humanity. Murder, and the atrocious crimes, are never heard of. Theft is extremely rare, forgery almost unknown, and bankruptcies and similar practices, so common in England, are regarded with abhorrence. Drunkenness scarcely ever appears in public, as in our streets; and when it does, it is not in the frightful and hideous

* The great proportion of deaths may be accounted for by the number of infirmaries and hospitals in Vienna, where many thousands die annually, who are sent thither for medical aid from all quarters of the empire. Nearly one half of them are sent when given up by their provincial physicians.

form of rage and fury, but a mixture of mirth and infantine folly, such as is described by Anacreon. If religion is to be judged by its fruits on the character, therefore, it will surely require an uncommon share of hatred to popery to reconcile us to the belief that that of the Austrian is a very bad one.

The great objection to the religious system of this fine principality, is its expensiveness. The church draws very nearly one-eleventh of the gross produce of the land, and a good deal more than one-fifth of the gross rental of the province. The rental, or portion, which is paid to the superiors of the lands by the peasants, who possess them in property, but pay heavy fees to those superiors, amounts to nearly five millions sterling annually; and the ecclesiastical establishment costs one million, or nearly six times as much as that of Scotland, of which the population and revenues are nearly upon a par with those of Austria!

Intimately connected with the religion of every country must be its public instruction in morals and science. There are in Austria 1151 primary or elementary schools, in which reading, writing, the principles of Christianity, and the common rules of arithmetic, are taught. There are 22 normal, and 14 principal schools for the learned languages, mathematics, belles lettres, and such branches as are usually taught in our academies, five gymnasia or colleges, and one university, viz. that of Vienna. This last is celebrated for its anatomical and medical school. The funds for the maintenance of these establishments are principally supplied by a land-tax, similar to our assessment for parochial schools; but there are also other funds of considerable amount, arising from the portion of the revenues of suppressed convents and monasteries, which have lately been appropriated to this purpose. In general the Austrians are much upon a par with the rest of the south of Catholic Germany in point of education; but they are greatly behind the Protestants of the north, and even of those of Swabia and the Palatinate. On looking into their churches, however, on Sundays, calendars and prayer books are seen in almost every one's hands, so that reading is universally understood. They pay too little attention to history, geography, and the state of the world around them, and seem to care for nothing beyond the limits of their own province. Many peasants of the better classes gravely asked us, "On which side of Russia was England? and, How many days sailing London was distant from France?" On shewing them the map of Europe, they could not conceive why the French armies should get easier access to them than to us, or how it could happen that so trifling a spot as Britain should subsidise Russia and Austria, and set the power of the continent at defiance. This sort of ignorance, however, is not peculiar to the Austrians; it is found among the common ranks in some degree every where, excepting in Great Britain and the west of France.

The Austrians are, generally speaking, a handsome and athletic race, composed principally of Germanic materials, but mixed with the productions of Hungary, Italy, and Bohemia: hence the darker complexion and blacker eyes, the bolder features and the more animated expression of the Austrian than of the Westphalian, Saxon, Prussian, or Franconian; and, probably, that beauty of face and person, which is perhaps incompatible with successive uniformity of parentage, and which we find most perceptible among nations composed of

mingled tribes. How different is the aspect of an English assembly from that of a Bengalee or a Chinese? In like manner the Austrian form and countenance are probably improved by the frequent intermarriages of the natives with their neighbours; and they partake of all the charms of variety, and of the interesting novelty of what we may almost call an harmonious contrast. In a family, of which the father is the son of a Croatian officer, who settled in Austria in his youth, and the mother an Upper Austrian lady, we saw the Grecian profile and eye-brows in the face of the eldest daughter, and opposite to her, at table, the mild blue eyes, fair complexion, and gigantic well spread chest of a genuine son of Hermann, in the figure of her brother. Of six children, the shape and expression of countenance were, in like manner, singularly divided, or rather moulded, as by a finer medium than that of either parent, into something resembling both indeed, but greatly superior to either. The family in question was uncommonly handsome, and probably more so than that of any indigenous Austrian pair.

Analogous to their natural constitutions and varieties of form, are the manners of the Austrian population. They may justly be called a sensual people, in the same manner as the aggregate of the European population deserves that title; *i. e.* they shew every inclination to gratify the propensities by which they are most powerfully solicited. They are as fond of dancing, noise, and gallantry, as the French; they have no more objection to a good dinner and a bottle of wine than an Englishman; no Italian can be more passionately enamoured of music; no Neapolitan of high sounding titles, of finery in clothes and equipages, or of religious parade; and no school-boy of play in every possible shape. This variety of tastes for pleasure may probably arise from the cause to which we have alluded: it has certainly stamped upon this people the impression of a sensual nation. But what holds true of few other nations, is strictly just when applied to the Austrian: they can rush from the ball or the banquet into the field of battle, and seem to enjoy the terrors of war no less than the pleasures which it destroys. Their sensuality never unmans or enervates them. Their hearts are as unsusceptible of fear as they are alive to delight; and nature seems to have given them the faculty of being contented in every place and emergency, whether in the comic theatre or the scene of blood, and whether running to their nuptials or to their graves. Nor is this equanimity the child either of phlegmatic indifference, or philosophical calculation: It is the effect of a constitutional felicity upon a people who have rarely felt either political oppression or religious persecution. The great mass of the population seem to be much at their ease: their houses are large and commodious; their lands fertile, and comparatively well cultivated; their cattle, horses, and domestic animals, well fed and judiciously managed; and their country better supplied with roads, bridges, salutary municipal regulations, (and these, too, pretty well executed) than any other province in Germany. From a long enjoyment of those advantages, and a consciousness of them, the general appearance of contentment and happiness which occurred in this fine province, as often as we visited it, in spite even of war and its attendant calamities, may be in some measure derived. That the national character is agreeable to a stranger to contemplate it, is certain; and therefore he willingly dwells on any peculiarity which may

rescue his speculations from the charge of a tedious and impertinent minuteness, while he describes the manners of a district, which, lying nearly in the centre of Europe, and having frequently made a figure in our history as the point of union of a powerful monarchy, might be supposed to be abundantly familiar to us in all its aspects.

Of the peculiarities which we remarked in the character of the great body of the Austrians, especially when travelling through the country at a distance from towns, we mention three as the most conspicuous.

1. The Austrian betrays complete indifference about public affairs, whether they respect his own country or Europe, and the world in general. He never asks for news, or listens to any discussions upon politics, or indeed any other general topics of a serious cast, but with the most evident indifference, or even aversion.

In no company is there a word heard concerning any public transactions or characters; and if a stranger chances, out of mere lack of conversation and to avoid the necessity of yawning, to make any allusion to subjects which he might think interesting to all who hear him, he is soon constrained to change his topic by the mortifying apathy with which his observations are received. We first imagined that this disposition to reject every thing serious or valuable in public life, as the occasional ground of converse, arose from timidity and the fear of giving offence to the government, or to persons in power; and we had frequently heard this reason assigned by the northern Germans as the cause of what they are pleased to call *Austrian slavery and submission*; but this is a mistake. The Austrian loves his sovereign, perhaps more than any other European, and has indeed good reason for so doing, in as far as the mildness of the government, and the humanity of its civil polity, are concerned. But this love does not incite him to any talking, or any praises. Neither do the reverses experienced by his prince extort from him any censure of the government, or any impatience under a system which threatens the dissolution of the monarchy. He seems to be naturally and instinctively averse to any speculations upon such matters, and to have received from his first entrance into the world, a bias the very reverse of that which is the characteristic of the British character. What a contrast, indeed, do these two yield on a stranger's arrival in a remote valley in upper Austria and in the Highlands of Scotland! The Austrian landlord receives him with a good natured countenance, and slowly shews him a room, and asks what he wants to have for dinner, &c.: then, perhaps, enquires about the roads, and what he paid for his horses and carriage; and how long he has been in Austria, &c.; but never dreams of asking news, or talking of any thing connected with public affairs. The Highland Scot torments his guest with a torrent of questions. "Whence he came to-day? Has he seen the last newspapers? What he thinks now of our ministry? How are matters going in Germany, Spain, India, America, and in all parts of the world?" with a geography of which he betrays a most wonderful acquaintance and familiarity; and, "When this war is to have an end? What he thinks of the last taxes, of the local militia, of the national debt now amounting to 500,000,000*l.*, and of the general state of the country?"

2. A striking peculiarity in the Austrian character, is the union of great physical vigour and ardent love of pleasure, with the most astonishing self-command, forbearance, and good nature. Quarrels, even among per-

sons intoxicated with spirituous liquors, are the most harmless things imaginable. They hardly ever come to any height, even in words; blows are scarcely heard of in many towns during a whole year; and maiming or murder is, on such occasions, completely unknown. There is probably more blood shed at one country market in Ireland, or at a quarrelsome drinking match in Wales, or the Highlands of Scotland, in one evening, than in the whole of Austria in twelve months.

3. An amiable peculiarity in the Austrian character, is the profound veneration paid to the memory of their deceased friends. This is the more striking, because the people are generally reckoned giddy and thoughtless, and believed to be affected chiefly by objects of present sensation. The proofs of it, however, constantly appear. Wheresoever a person has perished, either by a fall from a horse, by drowning, by being crushed to death by a tree or a carriage, or in short in any way out of the common run, a board, containing an inscription and paintings relative to the event, is hung up on the spot, and stands for many years as a monument in honour of the departed. Such boards or tickets, sometimes attended with considerable expense, are particularly numerous on the banks of lakes, and near precipices, and the ferries or fords of rivers. We have never seen any of them which exhibited marks of wantonness in being defaced by boys or passengers. The natives regard them with profound veneration, take off their hats as they pass by them, and mutter a prayer for the happiness of their friends. There is something peculiarly affecting in seeing this done with folded hands by young boys and girls as they go to the schools.

Consistent with this custom is the decency of their funerals, and the decorous state of their church-yards and tomb-stones. Nothing can exceed the care with which these are preserved, and nothing but sincere respect for the relation which once subsisted between the deceased and those whom they have left behind them, could prompt the latter to give so conspicuous an evidence of it.

The common amusements of the Austrians are shooting at a target, playing at ninepins, here, as in Saxony, called *kegel-schreiben*, billiards, cards, dancing (of which they are extravagantly fond,) and musical parties. They have no amusements which, like those of the British, cricket, golf, quoits, and wrestling, can be properly denominated athletic; nor do even their boys try their courage and strength by these violent, yet useful competitions, with which our youth are early initiated into the struggles and difficulties of life. A stranger is much struck with the placid and quiescent aspect of the German boys in general, but still more so with that of the Austrian, who are healthy, well fed, and evidently happy, although that happiness bears no resemblance with the loud, and sometimes mischievous and tempestuous mirth of the Britton.

The average Austrian stature of men is 5 feet 7½ inches, and of women 5 feet 3 inches English measure; but many instances of great stature occur, especially in the lower and fertile districts of the province. Their dress has nothing particular in it. We found no traces of the characteristic bigotry and immorality, with which some persons have, in other Encyclopædias, reproached this faithful and gallant nation: on the contrary, we can, from experience attest, that such reproaches are ill founded and calumnious. Englishmen ought, of all other travellers, to be the last to take up and circulate reports, injurious

to a country in which they are particularly well received; and it is but bare justice to the Austrians to say, that, in point of religious toleration, of good order, humanity, honesty, and whatever constitutes the public and private *morality* of a people, they are excelled perhaps by none on the continent of Europe.

Few countries are more productive than Austria in proportion to her extent, whether we refer to the animal, the vegetable, or the mineral kingdoms. Her breeds of horses, mules, asses, cattle, sheep, goats, hogs, and of all the common European domesticated animals, as well as of game and wild fowls, are acknowledged to be among the best in Germany. In 1798, there were 97,684 horses, and 112,162 head of cattle in Lower Austria, and probably one-third of those numbers in Upper Austria, and that too without reckoning the cattle destined for the shambles of Vienna, which last amount to nearly 80,000 at an average yearly, and 54,000 calves. (See VIENNA.) Much attention has been paid since the reign of Joseph II. to the breed of horses in Austria, by introducing English, Mecklenburgh, and the best Turkish stallions, and by encouraging English grooms to settle in the country. Nothing very particular, however, can be said in favour of their management of live stock; and productive as the province is, they must long continue to import considerable quantities from the adjoining provinces of Hungary, Bohemia, and Moravia, in order to meet the constantly increasing demands of Vienna. The same may be said of the other productions of the province, such as wood, wine, corn, fruit, oil, wool, iron, lime, &c. excepting the article of salt, which Upper Austria produces in quantities, not only adequate to the supply of the province and metropolis, but also sufficient to afford a considerable surplus for exportation.

Austria, when compared with the mass of the continental provinces of northern Europe, may fairly be stiled a well managed and rich agricultural country. On entering it, either from Hungary on the east, or from Bavaria on the west, we find a striking contrast in its favour. The country is pretty well and regularly enclosed, especially Upper Austria; a sort of rotation of white and green crops is observed; and the raising and harvesting of hay are perfectly well understood. Draining is not, indeed, scientifically practised, but embankments against lakes and rivers are very skilfully constructed, and kept in admirable condition all over the province. Irrigation is well managed, and carried on to a great extent, being found of vast advantage in a country which has abundance of running water, and of which the soil is for the most part rather light and gravelly than otherwise. The roads are good, and, upon the whole, well managed, though not always well engineered when first made, being, as in many parts of England, carried over the summits of hills and eminences that might have easily been avoided; and in some parts of the level country, where land is valuable, too narrow, in proportion to the great resort upon them. With regard to these hills, and all other dangerous or difficult parts of the road, the Austrian police shews great tenderness and humane attention to the people who pass by them. A ticket upon a tall pole, somewhat like a road-index, is placed in a conspicuous station by the road side, with the figure of a man crushed to death painted upon it, over whom a wheel has passed, while he was in the act of fastening a drag-chain to his cart or waggon; intimating the dangerous consequences of neglecting that precaution till the horses were so pushed by the weight of their draught, that they

could not command themselves. A fine to a considerable amount is also named on the same ticket, to be paid by every driver of a loaded carriage of whatsoever description, who shall not fasten his drag-chain to such carriage at the very place where the ticket is hung up. A reward is offered to informers; so that serious accidents, so frequent in Northern Germany, and other parts of Europe, very rarely happen in Austria, even on its steepest roads. The crops commonly cultivated are wheat, (in no very considerable quantities) barley, oats, rye, pease, beans, potatoes, saffron, mustard, hemp, flax, wood, and a few species of grasses, as clovers, vetches, tares, &c. In comparison with Northern Germany, (excepting some parts of Mecklenburgh and Holstein,) the crops are heavy and productive; but if compared with the best managed counties of England and Scotland, they are by no means considerable in proportion to the fertility of the soil. Six bolls, (Linlithgow measure,) or three quarters of wheat, are reckoned a good crop per acre, and four bolls of barley or oats rather exceed the common average. The Austrian peasant is not a *tenant*, in our sense of the word, but a *feuar*; he has his land very cheap, and calculates not upon what a certain quantity of seed corn will yield him. Hence he sows very sparingly, perhaps six or seven pecks, or two and a half bushels per acre, and is perfectly contented if he has six or seven returns from his seed. He ploughs to the depth of two, or at most three inches, and manages his ground precisely as his forefathers did in the days of Charles V., or of Rudolf of Habsburg. A great branch of husbandry in the country eastward of the Ens, and in which the natives excel most of their neighbours, is their wine. Perhaps one-sixth of the arable land of the whole of Lower Austria is occupied by vineyards, and these pay at least one-fourth of what we call the landed rent of the province. The wine here made is a white wine, of an acid taste, which, when kept for a year or two, is both palatable and wholesome, improves till the age of twenty years, and sells in wholesale from the cellar of the Vienna merchant at eight-pence sterling a bottle. The quantity consumed in Vienna and the province is prodigious, and, together with what is exported to the northward, amounted, at an average of ten years preceding 1809, to the sum of ten millions of florins, or 800,000*l. per annum*. The vineyard husbandry is the most laborious of all others, and makes the most attentive and regular farmers; hence the appearance of steady and systematical industry, which delights the traveller who comes into this province from any of the northern, western, and eastern provinces by which it is surrounded.

Austria is a considerable manufacturing province. Vienna alone contains 54,000 manufacturers in woollens, silks, cottons, leather, iron, steel, glass, porcelain or china-ware, paper, toys, household-furniture, dress-making, &c.; and exports, to the different provinces of the monarchy, the value of 1,200,000*l. sterling per annum* in manufactured goods. Lintz, in Upper Austria, has a cloth manufactory, which, in 1805, employed 3000 workmen in the town, and 7000 in the neighbourhood; and several towns on the northern side of the Danube possess woollen manufactures, though of inferior consequence. They are still greatly inferior to similar establishments in England and France; but make a conspicuous figure in Germany. The articles which they yield are, at an average, 30 *per cent.* dearer, and sometimes above 60 *per cent.* dearer than the same articles in Eng-

land, in proportion to their intrinsic value. The same may be said of their silks and cottons. The numerous prohibitory restrictions, and heavy imposts, are not only detrimental to the province with regard to its foreign commerce, but also extremely pernicious to the internal improvement of the different provinces of this empire. Joseph II., who rushed upon every project without mature deliberation, fancied that manufactures would flourish in consequence of prohibiting almost all goods of foreign fabric; but he lived long enough to see, that prohibitions, like all other legislative interferences with the commercial polity and national industry of a country, must be very cautiously managed, in order to produce any good effect; and that it is the wisdom of governments, rather to foster and direct the national energies, than to impel them by violent measures, or in any case substitute coercion in place of persuasion, and of gradual illumination and advancement.

The revenue of Austria Proper is usually estimated at one-sixth of that of the empire, which, in 1808, amounted to nearly 9,000,000*l.* sterling. This very considerable sum of 1,500,000*l.*, which exceeds some of the northern monarchies of Europe, arises from various sources, of which the metropolis Vienna furnishes a large share. A tax on offices, places and pensions, lottery, stamps, bank, the house and land tax, post-office, the heavy duty on salt, amounting nearly to 200 *per cent. ad valorem*, the duty on tobacco, mines and minerals, silks, cottons, and all imported merchandise, even articles of luxury and of common use from Hungary and Bohemia, the duties paid by breweries and distilleries, as well as by wines, whether consumed in the province, or exported, &c. comprehend the principal parts of this revenue. It is difficult to discover the precise amount of the revenue of any specific province of the Austrian empire, and, indeed, that of the totality of it; inasmuch, that authors, who treat of the political state of this country, are all at variance upon it. Ockhart states the revenues of the empire at 110,000,000 of florins; Hock at 100,000,000; the Political Journal of Frankfurt at 93,193,000; Norman at 120,000,000; and others fluctuate between 80,000,000 and 150,000,000. The florin is between 1*s.* 3*d.* to 1*s.* 8*d.* sterling.

The national debt of the Austrian empire it is impossible even to guess at with any tolerable degree of confidence. In Vienna it was commonly said, in 1807—8, to exceed 80,000,000*l.* sterling; and supposing Austria Proper to have incurred one-sixth, it has a burden of 13,000,000*l.* and upwards to liquidate from a revenue of 1,500,000*l.*

Amidst the present uncertainty and rapid vicissitudes of the continental powers, which may to-day possess numerous and well-appointed armies, but to-morrow see them annihilated by a preponderating and overwhelming conqueror, it is not a matter of very great importance to inquire into the precise numbers or organization of their standing armies. The Austrian army, unquestionably the best appointed and the most powerful, upon the whole, excepting the French, stood as follows in 1804 and 1805, and in March 1809 very nearly on the establishment of 1805:

	Men.
Peace establishment of 1804,	370,945
War establishment of 1805,	471,312

The Infantry, 271,871 men, was as follows, viz.

	Reg.	Batt.	Comp.	Men.
1. Troops of the line,	63	189	1008	193,587
2. Grenadiers,		21	126	14,364
3. Chasseurs,	1	2	10	2,140
4. Frontier militia,	17	246	144	53,000
5. Garrison troops,	3	7	28	7,000
6. Invalids,		5		1,780
Total,				271,871

Every regiment of the line consists of two companies of grenadiers, of 99 men each; two field battalions of six companies, each company of 182 men; and a depot battalion, always engaged in recruiting and disciplining for the regiment; consisting of four companies. The complement of each regiment of the line is 3175 men. The grenadiers are men picked out of the regiments; not the tallest, as with us, but those who appear to be the best soldiers. Thirty-nine regiments of the troops of the line are always in garrison in Austria, Bohemia, Moravia, and Silesia; and seven in Galicia. These provinces are divided into circles, for the purpose of maintaining and recruiting them. Hungary keeps up 12 regiments, which forms a corps of 47,000 men, and are recruiting in that kingdom. The frontier militia towards Turkey, consisting of 53,000 men, enjoy free lands instead of pay in time of peace; but the moment they are under marching orders, or put on the war establishment, their regular pay commences like that of the other troops. Some of these regiments, especially those of the Bannat of Temeswar, are very strong, consisting of 4215 men each.

Of this number of infantry of the line and militia, Upper and Lower Austria supply about one-tenth, or nearly 20,000.

The cavalry, 50,800 men, was as follows, viz.

	Reg.	Divis.	Men.
1. Cuirassiers,	8	24	9,600
2. Dragoons,	6	21	8,000
3. Light horse,	6	24	9,480
4. Huzzars,	12	48	18,980
5. Hulans,	3	12	4,740
Total,			50,800

Of these Hungary furnishes 18,000, which she recruits and maintains. Austria Proper contributes only one-twelfth, or 4200 men, and has usually but a few battalions in her garrisons.

The artillery was as follows, viz.

	Reg.	Batt.	Comp.	Men.
1. Field artillery,	4	16	64	12,800
2. Artillery-men,		1	4	1,274
3. Miners,			4	640
4. Sappers,			3	280
5. Bombardiers,			2	200
6. Pontoneers,		1	6	600
7. Engineers,				200
Total,				15,994

The artillery is furnished with recruits by the infantry, or by regular recruiting for the corps itself.

There are independent companies attached to the army, which amount to 12,000 men, and the emperor's body guard, consisting of the noble guard of Germany and Hungary,—the former 102 men, and the latter 69, all cavalry; and of 109 men of foot guards, who always reside in Vienna, and near the emperor's person.

The army expenditure amounts, in time of peace, to nearly two millions sterling, and in time of war to six or seven millions.—The following is given by some authors as the state of the Austrian army, at different periods of the monarchy, viz.

	A. D.	Men.
Under the Emperor Ferdinand II.	1629	150,000
Leopold I.	1673	60,000
Joseph I.	1706	133,000
Charles VI.	1735	150,000
Empress Maria Theresa,	1746	200,000
Emperor Joseph II.	1788	364,000
Francis II.	1809	470,000

By the late treaty with France, Austria has lost about one-eighth of her population, and one tenth of her resources; but she is still a *very respectable power*, and fully able, with proper management, to maintain her old military establishment, and even to increase it. Hungary alone contains a larger population than the Prussian monarchy ever did, and is much richer in every point of view, yet that kingdom has never supplied Austria with 100,000 men in any war, and Prussia had, in 1806, a regular army of 230,000 infantry, and 34,000 cavalry.

The Austrian empire consists, (in 1810.) of the following countries, which see in their order, viz.

	Inhabitants.
Austria Proper,	1,708,000
Bohemia,	5,022,000
Bukowina,	250,000
Carinthia, part of,	160,000
Carniola, part of,	20,000
Croatia, part of, and Sclavonia,	500,000
Hungary, with Transylvania,	11,500,000
Gallicia, Eastern,	3,650,000
Moravia, with Silesia,	1,655,000
Stiria,	860,000
Total,	25,525,000

For farther information respecting the history and statistics of the Austrian empire, see *Geographie und Statistik der gansen Oesterreichischen Monarchie* von K. Hammerdorfer, Leipzig, 1793. *Special-Statistik von Oesterreich*, von J. de Luca, 1797—8. *Statistisches Gemälde von Oesterreich*, V. And. AUTENQUA, a district of Africa, situated to the east of the Cape of Good Hope, and inhabited partly by Dutch colonists. Vaillant considers it as the most beautiful country in the world. The Dutch planters rear cattle, make butter, collect honey, and cut down timber, for the supply of the Cape. A more particular account of this district may be seen in Vaillant's *Travels*. (j)

AUTHENTIC CHORDS, in Music, are such common chords as have the 4th uppermost, as III or 3d 4th 4th 3d III

See COMMON Chord. (g)

AUTHENTIC MELODIES, in Music, are such whose principal notes lie between the key-note and its octave. See Dr Callcot's *Grammar*, Art. 184.; and PLAGAL Melodies. (g)

AUTOGRAPH, from *αυτος* and *γραφα* to write, is the original handwriting of any person. (j)

AUTOLYCUS, a Greek mathematician, was born at Pitanea, in Æolia, now the Lipari Isles, and flourished about the year 336 before Christ. He was mathematical preceptor to Arcesilaus, the disciple of Theophrastus; and it appears from a passage of Simplicius, that he proposed some hypotheses for explaining the motions of the stars, and was the author of some additions to the theories of Eudoxus. In his two works, entitled *De Ortu et occasu Siderum*, and *De Sphæra Mobilis*, the doctrine of the sphere, and various phenomena connected with the rising and setting of the stars, are rigorously demonstrated by the theory of spherics. See *Diogen. Laert.* lib. iv. p. 29. *Simplicius De Calo*, lib. ii. com. 46. *Fabric. Bibl. Græc.* tom. ii. p. 89. *Montucla, Hist. Math.* tom. i. p. 210. (v)

AUTOMATON, a self-moving machine, or machine so constructed, that, by means of internal springs and weights, it may move a considerable time as if endowed with life. (From *αυτος* *ipse*, and *μαωνας* *excitor*.) According to this definition, clocks and watches, as well as mechanical imitations of living animals, are automata.

We are told, that so long ago as 400 years before Christ, Arcliyas of Tarentum, a Pythagorean philoso-

plier, made a wooden pigeon that could fly. The story is related by Aulus Gellius, who quotes it from Favorinus; but neither have enabled us to understand how the effect was produced. Favorinus says, it it fell it could not raise itself again: and Aulus Gellius adds, that it flew by mechanical means, being suspended by balancing, and animated by a secretly inclosed aura of spirit. *Ita erat scilicet libramentis suspensum et aurâ spiritûs inclosâ atque occultâ consutum, &c.* (*Abetes Attica*, lib. 10. c. 12.) Several authors have related, particularly Kircher, Porta, Gassendi, Lana, and Bishop Wilkins, that the famous John Muller of Nuremberg, commonly called Regiomontanus, constructed a self-moving wooden eagle, which flew forth from the city of Nuremberg aloft in the air, met the Emperor Maximilian a good way off coming towards it; and, having saluted him, returned again, waiting on him to the city gates. This story has much the air of a romance, and more especially as some of the authorities, instead of the Emperor Maximilian, call it the Emperor Charles V. his grandson, who was born 64 years after the death of Muller. The same philosopher is also said to have made an iron fly, which, at a feast to which he had invited his familiar friends, flew forth from his hand, and, taking a round, returned thither again to the great astonishment of the beholders. This, if it was really performed, was probably nothing more than a magnetical trick.

M. Vaucanson, so celebrated for the construction of the mechanical flute-player, and mechanical pipe and tabor player, of which a description has been given under the article *ANDROIDES*, also invented a machine capable of imitating all the natural motions of a duck. In external form this machine exactly resembled its prototype: its wings were anatomically exact in every part; and every bone in the real duck had its representative in the automaton. Not a cavity, a curvature, or an apophysis, but was exactly imitated: the *humerus*, the *cuticulus*, and the *radius*, all had their proper movements. Besides this, the artificial duck imitated every natural motion of a real one. It swallowed its food with avidity, exhibited those quick motions of the head and throat which are peculiar to the living animal, and muddled the water which it drank with its bill exactly like the natural duck. It was capable of producing the sound of quacking; and what was perhaps most surprising of all, the food which it swallowed was evacuated in a digested state. M. Vaucanson, indeed, did not pretend to imitate the process of real digestion; but the food evacuated by his artificial duck was in a state very different from that in which it was swallowed; and this alteration was produced not upon the principles of mechanical trituration, but of chemical solution. M. Montucla, speaking of the machines of Vaucanson, says, that the first time he saw them, he immediately discovered some of the artifices employed in the construction of the two musical *Androides*; but he confesses that the artificial duck entirely baffled his penetration.

Towards the end of the 17th century, Father Truchet, of the Royal Academy of Sciences, constructed, for the amusement of Louis XIV., an automaton, consisting of a kind of moving pictures, which was considered as a master-piece in mechanics. One of these pictures, which the monarch called his *little opera*, represented an opera in five acts, and changed the decorations at the commencement of each. The actors performed their parts in pantomime. This moving picture was only 16½ inches in breadth, 12 inches 4 lines in height, and 1 inch 3

lines in thickness, for the play of the machinery. The representation could be stopped at pleasure, and made to recommence at the same place by the operation of a catch. The account of this piece of mechanism may be found in the eulogy on F. Truchet in the *Mem. of the Acad. of Sciences* for 1729.

A still more extraordinary piece of mechanism is that described by M. Camus, who says he constructed it for the amusement of Louis XIV. when a child. It consisted of a small coach drawn by two horses, in which was the figure of a lady, with a footman and page behind. According to the account given by M. Camus himself, this coach being placed at the extremity of a table of a determinate size, the coachman smacked his whip, and the horses immediately set out, moving their legs in a natural manner. When the carriage reached the edge of the table, it turned at a right angle, and proceeded along that edge. When it arrived opposite to the place where the king was seated, it stopped, and the page getting down opened the door; upon which the lady alighted, having in her hand a petition, which she presented with a curtsy. After waiting some time, she again curtsied, and re-entered the carriage; the page then resumed his place, the coachman whipped his horses, which began to move, and the footman, running after the carriage, jumped up behind it. It is to be regretted, says M. Montucla, that M. Camus, instead of confining himself to a general account of the mechanism which he employed to produce these effects, did not enter into a more minute description. See Montucla's Edit. of Ozanam's *Mathematical Recreations*.

Ingenuous pieces of machinery imitating the motions of men and animals are frequently attached to hour clocks, and brought into action at the end of the different hours. There is a remarkable clock of this kind at Lyons, and another at Strasburg. M. le Droz of la Chaux de Fonds, in the county of Neufchatel, was famous for constructing clocks of this kind. A very curious one, presented to his Spanish majesty, had, among other curiosities, a sheep which imitated the bleating of a natural one; and a dog watching a basket of fruit. When any one attempted to purloin the fruit, the dog gnashed his teeth and barked; and if it was actually taken away, he never ceased barking till it was restored.

Even the clock presented by the Kalif Haroun al Rashid to the French Emperor Charlemagne, deserves to be mentioned as a remarkable specimen of ingenuity, considering the time at which it was made. It was a clepsydra, or clock moved by water. In the dial were twelve small doors, forming the divisions of the hours; and each of these doors opened in succession at the hour marked, and let out little balls, which, falling on a brazen bell, struck the hour. The doors continued open till 12 o'clock, when twelve little knights, mounted on horseback, came out together, paraded round the dial, and shut all the doors. Such a machine might well astonish all Europe, at a time when the learned were wholly occupied by questions of grammar, or scholastic theology. See Bossut's *History of the Mathematics*. (m)

Besides these machines, many of extreme ingenuity have been constructed by skilful artists. Some are complicated, and perform a great variety of motions, in the course of which a series of different figures are introduced to view; while others are confined to the action of a single figure, and its appendages. Of the former

description are the machines composed of numerous parts, adapted for certain branches of trades and manufactures; or where all the successive operations of mining, carrying, and preparing the ore, are represented; or where cavalcades, processions, or sports, are shown. We have seen automatical exhibitions, imitating cascades of the most limpid water, and the blowing or closing of the petals of beautiful flowers. But the chief object of mechanics has been to imitate the action and faculties of living nature, in which they have succeeded in a manner surpassing belief. What relates to the motion of the human figure, we have treated of under the article *ANDROIDES*, already referred to; and we shall now continue briefly to advert to those of some animals, in addition to what is above mentioned.

We have seen the figure of a swan as large as life, which gracefully curved its neck, or turned it round as if to dress the plumage of its wings or body. Having done this, it bent down its head, and taking a metal fish in its bill, swallowed it. A peacock also has been constructed, which, by machinery, could erect or depress its crest, and unfold its tail; it could likewise lift a piece of money in its bill, while performing all the motions peculiar to an animated original. Perhaps these figures should excite less curiosity, from their larger size admitting of the greater complication of parts, and the more ample operation of the mechanical powers, at least if we compare them with others. Some automata of animals have been made so inconceivably small, and at the same time exhibiting such a diversity of action, as to claim the utmost admiration, not only of those unacquainted with the principles of art, but of the most intelligent mechanics. M. Maillardet, an artist on whom we before bestowed our commendations when speaking of the *Androïdes*, constructed an oval box about three inches in length: the lid flew up, and a bird of beautiful plumage, not larger than a small humming-bird, started up from its nest. Its wings fluttered, and its bill opening with the tremulous vibration peculiar to singing birds, it began to warble. After continuing a succession of notes which would fill a large apartment, it darted down into its nest, and the lid closed of itself. The machinery was here contained in very narrow compass, and could produce four different kinds of warbling: it was put in motion by springs, which preserved their action during four minutes. It has often created great surprise how such a variety of notes could be produced within a space where there was evidently no room for a corresponding number of pipes. The artist, however, has accomplished his purpose by a very simple expedient. There is only one tube, the vacuity of which is shortened or lengthened by a piston working inside, and thus producing sounds graver or more acute, according as the machinery operates upon it.

Still more minute is a spider, wholly fashioned of steel, of which we have seen several species. The mechanism effecting the motions of these figures, is included in the body, and by means of various springs, pinions, and levers, the legs are successively raised, and the automaton advances. One constructed by M. Maillardet, ran on the surface of a table during three minutes; and its course was so devised, as to tend rather towards the centre of the table than the edge.

The same mechanic has made an automatical caterpillar, or lizard, and a mouse, all strictly imitating the motions of nature. He has also constructed a serpent, which crawls about in every direction, opens its mouth,

hisses, and darts out its tongue. The source of motion, like that of the others, here consists in springs, and it continues in action seven minutes.

Other automata, as a ship on wheels concealed from view, men rowing a barge, the going of mills, and many other operations which require the human hand to regulate them, have often been contrived. But there is one kind of imitation of nature, which, perhaps, infinitely surpasses either the representations of animals or the *Androïdes*; we mean the imitation of speech. This may assuredly be considered as the utmost stretch of invention; for of all the faculties conferred on living beings, that which most eminently distinguishes man is speech.

A brazen head, we are told, was once constructed, which is said to have uttered words; but this probably consisted in deception only: nor is it wonderful that it should not have been easily detected, when we reflect on the propensity of the public lately to view one of little ingenuity with admiration. M. Kempelen, however, a Hungarian gentleman, who had previously distinguished himself by mechanical productions, has undoubtedly effected the imitation of speech where no deception is practised. We shall briefly advert to the principles he followed, as we believe no account of them whatever has hitherto been detailed in Britain.

M. Kempelen having directed his attention towards the practicability of forming a speaking machine, limited his expectations to the production of vowels only. At first he entertained no hopes of obtaining consonants, far less did he deem it possible to unite them with vowels, and thus express words or syllables. In the course of his investigations, he tried all musical instruments, even horns and trumpets, with a view of finding which of them emitted sounds approaching nearest to the human voice: but although he was aware that the reeds of hautboys, clarionets, and bassoons, came nearer the voice of mankind, because there is a faint resemblance between their operations and the functions of the human glottis, and also knew that a reed stop, called *voce humana*, had been adapted to organs, his researches were ineffectual. The sound of those reeds was found, on comparison, to be a very imperfect imitation of what they were intended to represent. At length having accidentally heard the reed of a bagpipe, he conceived that it exceeded all others in this respect, and thence made it the subject of his future experiments.

M. Kempelen then proceeded to a minute and assiduous study of the mode in which the human speech is produced, which has led to an interesting dissertation *On the Mechanism of Speech*. There the anatomical position of all the different organs is shewn and described, and also the different relations of each sound to another. After considering these things, he supposed that the fundamental part of voice consists in A. But this was far from aiding his purpose; and he could obtain no other vowel, whether grave or acute, from a reed connected with a tube. However, after long study, he contrived a hollow oval box, divided into halves, which were attached by a hinge, thus resembling jaws. These were adapted so as to receive the sound issuing from the tube; and by means of opening and closing them he heard the sounds A, O, OU, and an imperfect E; but no indications of I, or the German ü. His attention was next directed to consonants; and after the labour of two years, he obtained from different jaws P, M, L. With these vowels and consonants, he could compose syllables, and even words, as *mama*, *hafa*.

aula, lama, mulo, because each touch of his instrument produced a different sound. Still he had to conquer a great difficulty, in the first letter not having ceased when the second commenced; and on attempting to procure the sounds in immediate succession, the letters were confounded together. *Papa*, instead of being one word, evidently consisted of so many different letters; and also the too sudden discharge of air into the tube produced a faint K. Thus *aula* nearly resembled *ka-ku-kl-ka*. Another imperfection likewise arose in an aspiration following the consonant, and *faha* then resembled *fh-a-fh-a*. As M. Kempelen proceeded in ascertaining the possibility of producing the sound of letters, he surmounted these difficulties, though it cost him a great deal of trouble. But the proper combination of them he saw must result from imitating nature in having only one glottis, and one mouth, from which all the sounds should issue, and where their union should be formed. His invention therefore terminated in constructing a machine which, in some measure, imitated the human speech.

The speaking machine is of simple structure, and consists of only five principal parts. 1. The reed, representing the human glottis; 2. An air chest, with internal valves; 3. Bellows, or lungs; 4. A mouth, with its appurtenances; 5. Nostrils, as in the living subject. We shall not attempt to expatiate on each of these parts, which would lead to a long discussion; and in order to avoid this detail, we shall briefly explain, so far as we are able without figures, the general composition of each. The reed, though not cylindrical, is formed in imitation of the reed of a bagpipe drone, which probably many of those who peruse this article may have seen. The hollow portion, however, is square, and the tongue of the reed, which vibrates, consists of a thin ivory slip, resting upon it horizontally. This hollow portion, or tube, is inserted into the air chest; and the discharge of air occasioning a vibration of the ivory, the requisite sound is produced. To soften the vibration, the part supporting the slip is covered with leather, and a moveable spring, shifting along the upper side of the slip, brings the sound of the reed to the proper pitch. The sound is more acute as the spring is moved forward to the outer extremity, because the vibrations then become quicker; and if shifted farther from the anterior extremity, the sound becomes more grave, as the vibrations are then slower. The extremity of the ivory slip should not be applied close to the tube where it rests, but should remain a little open, that the air may penetrate and occasion the vibration. Thus we observe that a common bagpipe reed may be closed and produce no sound. A slight curvature of the ivory slip arises from the pressure of the spring, which is enough for the object desired.

One end of the air chest, which is of an oblong figure, receives this voice-pipe, as we shall call it, containing the reed; and into the opposite end is inserted the mouth of the bellows. Both the apertures are guarded by leather, to prevent the unnecessary waste of air. Two smaller air chests are then put into it, each having a valve above closed by the pressure of a spring, and each having a round aperture adapted to receive through the side of the large air chest a tin funnel, and a round wooden tube for producing hissing sounds as, *s, z, sch, j*. The voice-pipe is placed in the large air chest, so as to be between the smaller air chests.

When all these parts are fitted to the air chest, the

operation of one lever raising the valve of the first smaller chest connected with the tin funnel, sounds *s*; while the operation of another, raising the valve of the second smaller chest connected with the wooden tube, sounds *sch*. But it is proper further to explain, that, instead of being a simple funnel, it is in fact a tin box, with a square hole in the outer end, nearly covered by a slip of pasteboard; and the wooden tube is merely the mouth-piece of a common flute, closed at the lower extremity, and with the air-hole modified and contracted. The letter R is produced by the rapid vibration of the ivory slip, owing to a strong discharge of air.

M. Kempelen's bellows, which are formed to supply the place of lungs, have no peculiarities. He found that his machine required six times the quantity of air used by a man in speaking. The nozzle, as we have observed, is inserted into the large air chest, and the air which it discharges is also received by the small air chest.

With regard to the mouth, it consists of a funnel, or rather bell-shaped piece of elastic gum, applied to the air chest, and so adapted that the sound of the reed issues from it. Elastic gum is selected for this purpose, as more nearly approaching to the natural softness and flexibility of the human organs. Independent of its communication with the reed producing the sound required, a tin tube connects it with the air chest, by means of which it may be kept constantly full of air. This M. Kempelen considers a very essential, or even an indispensable part of the machine. Besides these there are small additional bellows, for the purpose of aiding the production of such sounds as P, K, T, which need a greater emission of air.

The nose consists of two tin tubes communicating with the mouth. When the mouth-piece is closed, and both tubes remain open, a perfect M. is heard; when one is closed, but the other is open, N is sounded.

It is necessary to add to this brief account of the principal parts of M. Kempelen's speaking machine, that the sound was regulated in a great measure by various modifications and compressions of the mouth. Four letters, D, G, K, T, he never could obtain perfectly, and substituted a P in expressing them, which was so managed as to bear a considerable resemblance, according to the mode of using it, and sufficient to deceive the auditor. Nevertheless M. Kempelen could produce not only words, but entire sentences: such as *opera, astronomy, Constantinopolis*; or *vous etes mon ami—je vous aime de tout mon cœur—Leopoldus secundus—Romanorum imperator semper Augustus*, and the like. We acknowledge ourselves ignorant of the precise figure under which this machine, no less remarkable for ingenuity than simplicity, was ultimately adopted. At first it was exhibited only with the union of its essential parts; M. Kempelen next proposed that it should be an automaton like a child; and although we have reason to believe that his intention was fulfilled, our uncertainty has induced us to place our account of it here rather than under ANDROIDES.

The more complicated automata are greatly prized in the East; and some years ago constituted a kind of traffic from Great Britain. China, we have understood, was the place where the greatest prices were given for them: and we know also, that some automata of ingenious workmanship were carried from this country with the last embassy, as the most acceptable present that could be offered to the Chinese emperor. (c)

AUTUN, the *Augustodunum* of the Romans, a city of France, in the department of the Saone and the Loire, situated near the river Arroux, at the foot of three great mountains which supply the town with water. Autun is not distinguished either by its magnitude or its public buildings. The ruins of three ancient temples, a theatre, and a pyramid, and two ancient gates, are the only objects which arrest the attention of the traveller.

In the neighbourhood of this town there are mines of iron, coal, and crystal, and in the canton of Mont Cenis there is a foundery of cannon. A mine of lead, with a mixture of silver, has been discovered near the town; but the expense of working it was not defrayed by the profits. The wood around Autun is very abundant, and is sent in great quantities to Paris for fuel, and for the purposes of carpenters. Population 9176. East Long. $4^{\circ} 17' 59''$; North Lat. $46^{\circ} 56' 48''$. See Gibbon's *Hist.* chap. xi. vol. ii. p. 27. See also SAONE AND LOIRE. (π)

AUVERGNE, the name of one of the provinces into which France was divided before the Revolution. It now forms the departments of CANTAL and PUY DE DOME, under which articles an account of its soil, productions, &c. will be found. See Gibbon's *Hist.* chap. xxxviii. vol. vi. p. 307. (j)

AUXERRE, a town in France, formerly the capital of the Auxerrois in the duchy of Bourgogne, but now the capital of the department of the Yonne. It is situated on the declivity of a hill near the river Yonne, which renders its situation favourable for commerce, and gives it an easy communication with Paris. Auxerre carries on a considerable trade in wines, of which it sends a great quantity to Paris and to the neighbouring provinces. Those of Coulange and Chablis are the most celebrated. The timber, which is also an article of commerce, is brought down by the rivers Cure and Yonne to Auxerre, from which it is sent to Paris by the Yonne and the Seine. The environs of this town are extremely beautiful. The palace of the bishop was one of the finest episcopal edifices in France; and the principal church is also much admired. Population 12,047. East Long. $3^{\circ} 34' 6''$; North Lat. $47^{\circ} 47' 57''$. See Peuchet's *Dict. Commerc.* vol. i. p. 672. (v)

AUXILIARY SCALES, in music, are, according to Martini and Keeble, any key major with its relative minor, and the attendant keys of each of these, six keys in all. See ATTENDANT *Keys*. (g)

AUXILIARY VERBS, are those which are prefixed to others, for the purpose of limiting their signification. See GRAMMAR. (j)

AUXONNE, a town of France, in the department of the Cote d'Or, situated near the river Saone. It is remarkable for a double wall built around it in the 17th century, and for a bridge of 23 arches over the Saone. The principal articles of trade are corn and wood. Population 5282. East Long. $5^{\circ} 23' 35''$; North Lat. $47^{\circ} 11' 24''$. See Peuchet's *Dict. Commerc.* vol. i. p. 673. (π)

AUZOUT, ADRIAN, a French astronomer, and one of the earliest members of the Academy of Sciences, was born at Rouen, and died in the year 1693. The honour of having invented the micrometer has generally been ascribed to Auzout by the French astronomers, but it is now perfectly ascertained, that he was merely an improver of that useful instrument. M. de la Hire, (*Mém. Acad.* 1719), M. le Monnier, (*Hist. Celeste*, p. 2.), and other French astronomers, maintain, that Auzout, at the same time with Picard, proposed to apply the

telescope to the quadrant. It is a remarkable circumstance, that both these inventions have been claimed by the English for Mr Gascoigne. Auzout was the author of some ingenious and interesting experiments on the light and heat of the different planets, which are contained in the *Memoirs* of the Academy, tom. vi. part ii. See Montucla, *Hist. Math.* tom. ii. p. 569. Bailly, *Hist. Astron. mod.* tom. ii. p. 293, 400. See also the article MICROMETER. (w)

AVENYDIHON, a name given to a set of enthusiasts in Wales, who are supposed to possess a gift, resembling what is called the second sight in Scotland. See Warrington's *Hist. of Wales*, p. 102. (j)

AWNING, a covering of canvas extended over the decks of a ship, to shelter it from the sun, rain, or wind. See Clerke's *Elements and Practice of Rigging*, vol. i. p. 149, 230. (j)

AXIM, or AKIM, a country of Africa, situated on the Gold Coast, and extending about seven leagues from the river Serpentino to the village of Bosna. The French, who were for some time masters of this country, were expelled in 1515 by the Portuguese, who protected themselves by a fort. Axim remained in their possession, and they engrossed all the commerce of the Gold Coast till the 9th February 1692, when the Dutch attacked them, and made themselves masters of the district. Some time afterwards the Prussians arrived, and allured from their allegiance to the Dutch about one half of the natives. The fort belonging to the Dutch is called St Anthony, and that of the Prussians, Fredericksburg.

The soil of Axim is extremely fertile, and produces great quantities of rice, which the inhabitants export to the other kingdoms on the coast for palm-oil, yams, and millet. Its other productions are fruits of all kinds, black cattle, sheep, goats, and fowls. The gold of Axim, which is reckoned the best on the Gold Coast, is a considerable object of commerce. The Dutch have used every exertion to exclude other nations from this valuable traffic; and the negroes find it difficult to deceive them, as the chief village Ahambene, or Axim, is under the cannon of Fort St Anthony. The negroes, however, often carry the gold which they collect in the rivers, and in the interior of the country, to the English and Irish smuggling vessels, from whom they obtain articles of European merchandize at a much cheaper rate than they do from the Dutch.

The inhabitants of Axim also carry on a traffic in ivory and slaves, and likewise in large canoes, which they sell to foreigners, for the convenience of landing with facility on their rocky coast. Salt is manufactured in considerable quantities by the female negroes.

The government of Axim is entrusted to two classes of the natives; the Caboceroes, or chief men, and the Muncaroes, or young men. The principles of equity and humanity guide them in the administration of justice, and in the management of their public concerns; but bribery and corruption often defeat the great ends of public justice. See *Modern Univers. Hist.* vol. xiii. p. 391. (q)

AXIOM, a truth, or proposition, which is self-evident.

AXIS IN PERITROCHIO, or WHEEL AND AXLE. See MECHANICS.

AXMINSTER, an ancient town in Devonshire, is pleasantly situated on a rising ground upon the western banks of the river Axe, 26 miles east from Exeter. T 2

is famous for the burying-place of the Saxon nobles, who fell when resisting an invasion of the Danes, in the battle of Brunenburg; and for the monastery which King Athelstan founded for seven priests to pray for the souls of the departed warriors. This building, however, has been almost entirely destroyed, and from what now remains, it is impossible to distinguish either its character or original size. The town contains 406 houses, and is clean, neat, and healthy. It has an extensive manufactory for weaving carpets after the Turkish fashion, whose peculiar make and character have obtained them the name of Axminster carpets. The weekly market, which is held here on Saturday, is reckoned the first in the county. Population 2154. W. Long. 3° 8'; N. Lat. 50° 45'. See *Beauties of England and Wales*, vol. iv. and Polwhele's *Hist. of Devon*, vol. ii. p. 288. (*h*)

AXUM, a town of Abyssinia, in the province of Tigré, is remarkable only for its extensive and magnificent ruins, from which may be traced its ancient splendour and importance. In one square, which appears to have been the centre of the town, are forty obelisks of granite. On the top of one is a patera, exceedingly well carved, in the Greek taste; but the sculptures on the face of the obelisk are Gothic; and from its form and situation, Mr Bruce supposes it to have been erected by Ptolemy Evergetes, for the use of the philosopher Eratosthenes, in ascertaining the latitude, or according to others, in measuring the obliquity of the ecliptic. Two flights of steps, several hundred feet long, are the only remains of a magnificent temple; and in the vicinity are a considerable number of pedestals of statues; and the remains of a causeway, formed of large stones standing edgewise, or heaped upon one another.

The ancient city of Axum is supposed, by Mr Bruce, to have been built by a colony of Cushites, or Troglodyte Ethiopians. It was one of the most flourishing and populous cities of Abyssinia, and it continued to be the capital of the kingdom till the beginning of the 16th century, when it was destroyed by the Turks.

The ruins of Axum, of which we have given a short account, upon the authority of Bruce, in the article *ABYSSINIA*, have been recently examined with great attention by Lord Valentia. After much fruitless search, he was unable to find the inscription mentioned by Bruce; but was so fortunate as to discover a monument, about eight feet high, three and a half broad, and one thick, which contained a long Greek inscription. This monument seems to have been erected about the year 330, by Aizanas, king of the Axomites, in honour of his two brothers, who subdued the insurgent nation of the Bougæitæ, (perhaps the Bogenses of Edrisi.) This inscription contains an account of the hospitality shewn to the prisoners who were taken, and establishes the fact of Axum having been the capital of a people called the Axomites.

Lord Valentia measured and carefully examined all the obelisks at Axum. There are seven large ones, ornamented in the same manner as the large and beautiful one mentioned by Bruce, which is still standing, and which is 80 feet high, consisting of a single block of granite. The smallest is 36 feet, but the dimensions of the largest are considerably greater than those of the erect one.

Not far from the church, in a square inclosure surrounded with pillars, Lord Valentia found a short inscrip-

tion, in Ethiopic characters, to this effect: "The Aboona David removed and broke to pieces here; he thought within himself, the Lord was pleased that he so should do." This explanation seems to account for the destruction of the temple and obelisks. These ancient monuments, originally 55 in number, are said by the priests to have been built by Ethiopus, the father of Abyssinia, about 1540 years ago.

The present town, which contains about 600 houses, stands partly in, and partly at, the mouth of a nook formed by two hills, on the north-west end of an extensive valley, where the soil, which is very productive, is interspersed with small pieces of spar and agates. Several manufactures of coarse cotton-cloth are carried on here; and excellent parchment is made of goats' skins by the monks. N. Lat. 14° 6' 36", E. Long. 38° 39'. See Bruce's *Travels*, vol. iii. p. 128, &c.; and Lord Valentia's *Travels*, vol. iii. p. 87, 179. (*π*)

AXYRIS, a genus of plants of the class *Monœcia*, and order *Triandria*. See *BOTANY*. (*ω*)

AYE AYE, the name given by the inhabitants of Madagascar to a singular species of quadruped like a squirrel, discovered by Sonnerat. See Sonnerat's *Voyage to the East Indies*, tom. ii. p. 137. (*ω*)

AYENIA, a genus of plants of the class *Pentandria*, and order *Monogynia*. See *BOTANY*. (*ω*)

AYESHA, the wife of Mahomet. See *ARABIA*.

AYLESBURY, an ancient borough of England in Buckinghamshire, is situated on a branch of the Thames, in the pleasant and fertile vale of Aylesbury. It was formerly a place of considerable strength, and was taken from the Britons by the Saxons under Cuthwulf in 572. It was made a royal manor by William the Conqueror, who granted it to William of Aylesbury, under the singular tenure, that he should find straw for the king's bed-chamber three times a-year, should the king pass that way so often; and provide his table with two green geese in summer, and in winter with three eels. This town is the most considerable in the county; and, from the irregular formation of its streets and lanes, extends over a great surface of ground. It sends two members to parliament; and here are held the quarter-sessions for the county, and the Lent assizes. It contains 679 houses. The lower classes of the inhabitants are principally employed in lace-making. Population 3186. N. Lat. 51° 49' 18"; W. Long. 0° 50' 18". See Britton's *Beauties of England and Wales*, vol. i. p. 343, &c. (*h*)

AYLESFORD, a town of England, in the county of Kent, lies on the northern bank of the river Medway, and derived its name from a bloody battle which was fought here by the Angles or Saxons under Hengist, and the Britons under Vortimer in 455, Aylesford being merely a contraction for *Anglesford*. In the neighbourhood are shewn the burying places of Horsa the brother of Hengist, and Cotigern the brother of Vortimer, who fell fighting hand to hand in this engagement. Here is a handsome stone bridge of six arches over the Medway; a hospital for six poor people, each of whom receives ten pounds a year; and the remains of a monastery of Carmelites, now converted into a mansion-house of the earl of Aylesford. Houses 151, and population 912. N. Lat. 51° 21'; E. Long. 0° 28'. See Hasted's *Hist. of Kent*. (*h*)

AYLMER, or ÆLMER, JOHN, bishop of London, was descended from an ancient family, and was born at Aylmer-hall, in the county of Norfolk, in 1521. Being a younger son, and destined for the church, he was educa-

ted at Cambridge, under the patronage of the duke of Suffolk, who, pleased with his application and early attainments, received him into his family as preceptor to his children. One of these was the amiable but unfortunate Lady Jane Grey, who, under the care of Aylmer, soon became a proficient in classical literature. By his preferment to the arch-deaconry of Stow, Aylmer had a seat in the convocation held in the first year of queen Mary, where he resolutely opposed the return to Popery, and zealously maintained the doctrines of the Reformation. But the persecutions which followed compelled him to quit the kingdom. While abroad, he visited most of the universities on the continent; and wrote an answer to John Knox's "First Blast against the monstrous Regiment and Empire of Women," which he entitled, "An Harborowe for faithful and trewe subjects against the late bloune Blaste concerning the Government of Women, &c." Returning to England, on the accession of Elizabeth, he was presented to the arch-deaconry of Lincoln, and sat in the famous synod which was held in 1562, for reforming and settling the doctrines and discipline of the church of England. In 1576, he was raised to the see of London, in which he continued until his death, in 1594, at the age of 73. Bishop Aylmer was a bold and zealous advocate in the cause of the Reformation, and equally an enemy to the Puritans and Papists. He was most assiduous in public preaching, and performed the sacred duties of his office with a conscientious regard for the spiritual welfare of his people, and the good of the church. He was a man of considerable learning and abilities, but rather of an irritable and persecuting spirit; and his unwarrantable attacks upon the puritan clergy, and the virulent abuse with which he treated them, drew upon him a retaliation no less acrimonious; for, according to Fuller, he was the hero of the celebrated Martin Mar-Prelate. See Andrew's *Hist. of G. Britain*, vol. i. p. 524. *Biog. Brit.* (h)

AYR, or AIR, (anciently named *Vidogara*), a river which rises from Glenbuck, on the boundary between Lanarkshire and Ayrshire, and, after running thirty miles westward, falls into the Firth of Clyde at the harbour of Ayr. This river divides the county into two portions not very unequal; and it is possible that the present name might originate from this very circumstance. The inland boundary of Ayrshire, as it appears in ancient maps, is incurvated almost in the form of a bow, and if the line of coast be considered as the string, the river, which bisects it and extends to the most prominent part, nearly in the direction of an arrow in a bow, might be called *ARWÆ*, on the same principle which has given the name of *sagittal* suture to the synarthrosis between the parietal bones of the cranium. This etymology, suggested by a whimsical writer, is not more unsatisfactory than many others which have been assigned to the word. The poet Jonston has no hesitation in deriving it from the purity of the atmosphere; and he awkwardly hints, that its resemblance to the Latin *Aurum* implies some affinity to gold. Some learned persons choose to say, that the name of this river signifies *water*, others *shallow*, others *clear*, others *rapid*; not one of which terms can be admitted to form a distinction between it and the other rivers in the county. There is no doubt, that in many languages a word similar to this signifies *water*, *air*, *fire*, or some other fluid; and probably these significations are all derived from the Heb. *אָר*, *to flow*. It is most probable that the modern *Ayr* is only the termination of the ancient

name, *Fiodach-Ar*, or *Gwddawg-Ar*, (whence *Vidogara* was formed,) signifying the *sylican river*, or the *river in the forest*.

For about fifteen miles from its source the river possesses no beauties. The remaining half of its course is very romantic. The banks, in most places, are precipitous and rocky, clothed with natural wood, and the dusky stream below winds its way round these steep eminences, many of which have also been decorated by modern improvements.

AYR, or AIR, (formerly *Are*), a very ancient town on the west coast of Scotland, and the capital of Ayrshire, is situate on the southern bank of the river of the same name, at its influx into the Firth of Clyde. To the parish of Ayr that of Alloway was annexed early in the 18th century; but the lauds granted in the charter of the borough, (most of which have long been alienated,) extended over the whole of these now united parishes. The present rental of this royalty is 10,000*l.* per annum, and the number of acres is above 5000. Fifty years ago the state of agriculture was so wretched, that in the parish of Alloway the farmers could not afford to pay 1*s.* 3*d.* of rent per acre.

In former times this town was a place of considerable military importance. Though nature has not afforded it any remarkable facilities for defence, there is reason to believe that it was fortified at a very remote period. No trace remains of the more ancient places of strength, which are obscurely hinted at in the traditional records of the vulgar; but it is known that in 1197, William, surnamed the Lion, built a castle at the mouth of the river. A few years afterwards, this prince, whose charters to royal boroughs are the oldest now extant, erected a borough at his *New-castle-upon-Are*. The charter, having no year affixed to it, is generally supposed to have been granted about the year 1180; but the date appears, from internal evidence, to have been twenty years later. As it contains a reference to the new castle, it must have been posterior to the year 1197; and as the first witness, Florence, archbishop of Glasgow, is designed *electo Glasguensi Cancellario mee*, it could not be earlier than 1202, the year in which that prelate was advanced to the high office of chancellor.

The borough is under the government of a provost, two bailies, a dean of guild, a treasurer, and twelve counsellors; and, along with Irvine, Rothesay, Inverary, and Campbeltown, enjoys the privilege of sending a burghess to serve in the United Parliament. Very few boroughs, either in Great Britain or Ireland, are so little embroiled with party politics, and so little under the influence of great families. The chief magistrate, and leading members of the council, have generally been men of good education, public spirit, and liberal views; and yet some of the most obvious and indispensable matters, connected with police, have been strangely overlooked.

The town can boast of few advantages in point of appearance. The houses are set down so awkwardly, and (as it were) fortuitously, that it is impossible to conceive that the former inhabitants consulted either neatness or convenience, when they produced such uncouth and amorphous combinations. Even in the principal street, the eye is hurt perpetually by observing the contiguous buildings protruding beyond each other, in almost every possible direction, one perhaps standing square to the front, another shouldering obliquely forward, and a third facing to the right or left. Here you see a state-

ly edifice, rearing its gigantic form over a diminutive hovel, with scarcely a door or window. This circumstance is perhaps favourable to the view of the town from a distance, as the great inequality of surface produces something of a turreted appearance, and compensates for the small number of spires. This street has been compared to a crescent, but with no propriety, unless any crooked line, full of indentations, can be called a crescent. The streets are ill lighted, wretchedly paved, and very insufficiently cleaned. Side-pavements of flag-stones, for foot passengers, may be mentioned among the *desiderata*, which, in a situation like Ayr, might easily be supplied; and this very practicable improvement would surely conduce greatly to the comfort of the inhabitants.

The prison, like the old tolbooth of Edinburgh, interlines, and almost blocks up, one of the principal streets. Security is the only consideration which seems to have gained the attention of those who planned this public nuisance, which is not so much the terror of evil doers, as the horror of those who do well. The air is admitted very sparingly, and the accommodation is so inadequate, that old and young, male and female prisoners, are frequently crowded into the same apartment. We are astonished that a great county like Ayrshire should be so far behind many less populous districts, in effecting an improvement, which, more than almost any other, marks the superiority of modern civilization.

There are few public buildings worthy of particular notice. Before the Reformation there were monasteries of Dominicans and Franciscans, the former founded in 1230, and the latter in 1472. The church of St John the Baptist stood near the sea, and probably within the ramparts. Its tower still remains. Here, it is said, a parliament was held, in the time of Robert Bruce, to settle the succession to the throne of Scotland. This venerable structure continued to be the place of public worship till the middle of the 17th century, when it was converted into an armoury by Oliver Cromwell, who built a citadel round it; the stones for erecting which were almost all brought from a distance by sea, and chiefly from the castle of Ardrossan, a distance of twenty miles. The citadel encloses twelve acres of ground. Cromwell gave the town 66*l.*: 13: 4 sterling, to build the present church, which is capable of containing nearly 2000 persons. Another church has been recently built, which accommodates 1200.

In 1796, an academy was established here, and a handsome building erected, containing a number of spacious apartments, in which all the branches of education necessary for a commercial life are taught by able masters. The institution is superintended by a rector, who teaches experimental philosophy, astronomy, chemistry, Greek, &c. Other masters are appointed for mathematics, geography, navigation, arithmetic, Latin, French, English, writing, and drawing. The number of students last year amounted to 542. Within these few years, two rectors of this academy have been elected professors of natural philosophy in the two oldest Scottish universities. Besides this prosperous seminary, there are several other respectable schools, and in particular one or two female boarding schools.

A flourishing banking company, under the firm of Hunters and Co., has existed in Ayr for many years; and has a branch at Irvine, and another at Maybole. The Bank of Scotland has also an agent at Ayr.

The manufactures are not very considerable. Tanning and soap-boiling deserve to be mentioned.

The port was formerly considered as of no small consequence. Buchanan characterises it as "*Emporium non ignobile.*" The navigation, however, is liable to be impeded by a bar, which is occasionally thrown across the mouth of the river, especially by the N. W. winds; and the depth of water, even at spring tides, is but 12 feet. The foundation of a harbour was laid in 1772, a year memorable also for the failure of the Douglas and Heron bank. To this port belong at present 60 vessels; from 200 tons register downwards, the whole tonnage of which amounts to between 5000 and 6000. The seamen employed are 500. The principal export is coal to Ireland, about 50,400 tons annually. The other exports are pigiron from Muirkirk and Glenbuck, 1000 tons; coal-tar, 650 casks; brown paint, 470 casks; lamp-black, 700 barrels; coal-oil, 26 puncheons; soapers' salts, 170 tons; also *water of Ayr stone*, and black-lead; with boots, shoes, stockings, linens, cottons, wool, yarn, cheese, seeds, farming utensils, machinery, &c. The imports are hides and tallow from S. America; beef, butter, barley, beans, oats, meal, yarn, linen, feathers, kelp, bricks, quills, soap, and limestone, (about 8000 tons annually,) from Ireland; wheat, square timber, spars, and deals, from the British colonies in America; hemp, pitch, tar, iron, timber, &c. from the Baltic; slates from Easdale and Port-William; grain and meal from Galloway; British spirits and general goods from Glasgow; oak-timber, &c. from the west of England; and general cargoes from Leith, Liverpool, London, &c.

Contiguous to the harbour, and within the precincts of Cromwell's Fort, are barracks capable of containing a battalion of infantry.

The inhabitants in general are industrious and sober; and the more opulent part of them equally distinguished for their hospitality to strangers, and their humanity to the poor. A charity-house was built in 1756; and various other means have been provided for relieving the necessities of the helpless and infirm. One expedient in particular deserves, we think, to be made known, as its beneficial effects have been extensively felt among the lower orders. Within the last twelve years, six female societies have been formed: the first of which consists of 45 honorary members, and 70 general members, as they are called. Every member pays six shillings annually into the funds; and every ordinary member, when unable to work, receives five shillings a week. They receive also two guineas each when they are married; half-a-guinea for every child that is born; and when they die two guineas are paid for their funeral expenses. Some of the other societies are conducted on a principle somewhat different; but all of them are under the management of ladies, and the regulations are such as tend equally to guard against imposition, and to secure immediate relief to the distressed. The number of females associated for this purpose is 645.

It has sometimes been regretted that there is no infirmary or bridewell in Ayr. The want of the former must be felt chiefly by the medical practitioners, who might, by such an establishment, be saved a great deal of inconvenience. In all cases of necessity, these gentlemen are in the habit of giving their advice and attendance gratuitously, and this with equal assiduity and tenderness.

The markets are well supplied with provisions of all sorts, particularly fish, at moderate prices. Coal is

abundant and very cheap. The climate is healthy, and the society more agreeable than is generally to be met with in small towns. A public library has long been established; and, for several years there has been a printing-office, where a newspaper is published weekly. A number of neat villas and elegant houses have lately been added to the immediate vicinity; and it is to be hoped that in a short time the daily increasing beauty of the environs will be sufficient to withdraw the attention from the prominent deformities of the ancient streets.

The population, in 1801, was stated at 5492; but none of the sailors belonging to the towns were included; so that, from this and some other circumstances, the females appeared to be more numerous than the males by more than one-fourth. A greater disparity appears in many other lists; a strong presumption that the *census* alluded to was very inaccurately taken. The present number in the borough of Ayr may be estimated at 7000; and if we add the adjoining villages of Newton and Wallacetown, which are connected with this town by two bridges, the amount can scarcely be under 11,000. This parish claims the honour of having given birth to Joannes Erigena, Chevalier Ramsay, and Robert Burns. N. Lat. 55° 27', W. Long. 4° 37'. —Distance from Edinburgh 76 miles; from Glasgow 34.

AYR, NEWTON-UPON; a borough of regality on the north side of the river Ayr; the property of which is held by a very peculiar tenure, (described in the *Statist. Account of Scotl.* vol. 2.) On the confines of this small parish is an hospital, called *King-Case*, founded by Robert Bruce for eight leprous persons. The town itself is of great, though uncertain, antiquity. A number of boats are employed in fishing; and a considerable quantity of coal is exported. Some ships are built on this side of the harbour of Ayr; and for several years past a rope-work has been established. Population nearly 2000.

AYRSHIRE, a maritime county in the west of Scotland, bounded on the south by Wigtonshire and the stewartry of Kirkcudbright, on the east by Dumfriesshire and Lanarkshire, on the north by Renfrewshire, and on the west by the Firth of Clyde, and the Irish sea. Its length along the coast is above 80 miles; and its greatest breadth from west to east about 32 miles. It contains three districts, (formerly denominated the three bailliaries of Scotland) Carrick, on the south of the river Doon,—Cunningham, on the north of the Irvine,—and Kyle, or Coil, which occupies the intermediate space, and which is subdivided, by the river Ayr, into King's Kyle, and Kyle Stewart. It includes the rock of Ailsa, and the two islands called Cumbræes, or Cambrays. The number of parishes within the county is 47. It is said to contain 1040 square miles, or 665,600 English acres. In 1801, the number of inhabitants was reported to the House of Commons to be 84,506. In 1755, it had been stated at 59,268, and in 1790—1798, at 75,544. The valued rent is 149,595*l.* Scots; and in 1796, Sir John Sinclair estimated the real rent at 112,752*l.* sterling. The following is an accurate statement of the real rental for 1808:

	<i>l.</i>	<i>s.</i>
District of Cunningham.	127,632	4
Kyle,	113,462	3
Carrick,	63,724	0
Royalty or parish of Ayr (in Kyle,)	9,855	0
Total,	314,673	7

The general appearance of the county, though not remarkably variegated, cannot easily be characterised in a few words. Carrick, we think, is the most interesting, though not the most fertile district. Its coast, extending from the Doon to Loch Ryan, (which some maintain is the *'Ουιδουρμα*, and others the *Περγουλιος και-πεε* of Ptolemy,) is occasionally bold and rocky; and its southern limit is enclosed by a lofty ridge of hills, (the *Uxellum Montes*) partly green, and partly clothed with heath. The intervening space between the shore and the mountains is, for the most part, a gradual, but not uniform, ascent. The surface is diversified by numerous acclivities, some of them gentle, others more abrupt, separated from each other by rivulets not “unknown in song,” quietly stealing along verdant meadows, or pouring their foamy waters under the beeching foliage of sequestered dells, which have been successively occupied as the lurking-places of freebooting desperadoes, the retreats of unfortunate heroes, and the favourite haunts of the loves and the muses. The chief of these streams, overhung with natural wood, are the Girvan and the Stinchar, or Ardstinchar, a sound not easily adapted to the melody of verse, but still less uncouth than the names of its tributary brooks, Muick, Feoch, Ashil, and Dusk. Indeed most of the rivers in Ayrshire have names insufferably harsh and grating to the ear. With regard to Carrick, we shall only remark farther, that, though it contains many picturesque charms, many fairy landscapes, and many glens incomparably romantic, and though, from its vicinity to the ocean, it reveals some magnificent prospects, it does not possess within itself either the grandeur or the sweetness, either the richness or the gaiety, which enliven the Arcadian scenery on the Tay, the Tweed, and the Teviot.

Kyle, or Coil, having once been a forest, may have taken its name from that circumstance, (the Celtic *Coill* signifying *wood*) but the natives, misled probably by the old chroniclers, derive it from Coilus, a British king, who is reported to have fallen in battle somewhere on the river Coil, and to have been buried either at Coylton, or at Coilsfield. If such a personage ever existed, this does not appear to have been the scene either of his actions or of his misfortunes. The hill country, towards the east, is bleak, marshy, uncultivated, and uninteresting; and on that side, except at one or two places, the district was formerly impervious. In advancing from these heights to the sea, the symptoms of fertility and the beneficial effects of cultivation, rapidly multiply; but there is no “sweet interchange of hill and valley,” no sprightliness of transition, no bold and airy touches, either to surprise or delight. There is little variety, or even distinctness of outline, except where the vermiculations of the river are marked by deep fringes of wood waving over the shelvy banks, or where the long and almost rectilinear summit of the brown Carrick terminates abruptly in a rugged foreland; or where the multitudinous islands and hills beyond the sea exalt their colossal heads above the waves, and lend an exterior beauty to that heavy continuity of flatness, which, from the higher grounds of Kyle, appears to pervade nearly the whole of its surface. The slope, both here and in Cunningham, is pitted with numberless shallow depressions, which are surmounted by slender prominences, rarely swelling beyond the magnitude of hillocks, or knolls. Over this dull expanse the hand of art has spread some exquisite embellishments, which, in a great measure, atone for the

native insipidity of the scene, but which might be still farther heightened by covering many of these spaces with additional woods, free from the dismal intermixture of Scotch fir, a tree which predominates infinitely too much all over the country, deforming what is beautiful, and shedding a deeper gloom on what is already more than sufficiently cheerless.

Cunningham is said by Buchanan to be a word of Danish extraction, denoting a king's habitation; and hence he infers, that the region was in possession of the Danes before it received this denomination. It is less fanciful to derive the name from the Saxon word, signifying a place where conies or rabbits burrow, an appellation which suits the district well, as its sandy downs abound with rabbit warrens to this day. This fertile tract of country is divided among a few great proprietors. It is decorated only by a small number of gentlemen's residences; but it contains several populous towns, and the harbours of Irvine, Saltcoats, and Ardrossan. With the exception of Largs, which is circumscribed within a rocky frontier, so as to be insulated from the surrounding country, almost the whole of Cunningham declines gradually towards the sea, presenting on all sides a rich and extensive prospect, finely contrasted with the islands in the Firth of Clyde, the Cumbraes, Bute, Arran, and the distant mountains of Argyleshire. When it is skillfully cultivated, it will rank with the finest plains in the whole of Scotland.

Formerly the baronies of Cunningham and Largs were under the jurisdiction of the borough of Irvine. The Earls of Cassilis were hereditary bailiffs of Carrick; the Campbells of Loudon were hereditary bailiffs of Kyle; and the Wallaces, lords of Craigie, were heritable stewards.

There are many lakes in this county, some of them extensive, but none very remarkable either for the beauty or the wildness of the scenery. The shore in general is very flat, and kelp is found in various places; but little attention has hitherto been paid to the manufacture of this valuable substance.

With respect to the climate, it is observable that there is much more rain in general on the western than on the eastern coast of Scotland, and particularly in the autumnal and winter months. In the spring, however, the west has the advantage. The easterly winds are not by any means so hurtful to vegetation, or so intolerably chilly in that part of the island, as they are in the vicinity of the German Ocean; and the uncomfortable fogs, which prevail so frequently on the Firth of Forth, are comparatively little known in Ayrshire.

There is considerable diversity of soil in this county. Near the shore it is for the most part sandy, but in many places intermixed with a rich loam. In other places gravelly soils prevail; but not to a very great extent. A large proportion of the soil is a stiff deep clay, which produces very abundant crops, when carefully managed. In some situations, the clay is merely superficial, lying over a substratum of scistus or till. Towards the east, where the grounds are highest, there is a great predominance of fen and peat-moss.

Till of late years the state of agriculture in Ayrshire is described as having been barbarous in the extreme. A most deplorable picture is drawn by Col. Fullarton of the wretchedness, ignorance, and apathy, in which the farmers were sunk till the middle of the last century; and it appears that it required no ordinary efforts to emancipate them from the degradation to which they had long been doomed, not by the rigour of their super-

mors, but by their own prejudices. We lament to state, that the means which were thought necessary to rouse them from their torpor, have tended to retard rather than to accelerate the progress of good husbandry. With a view to enforce the observance of an improved system, Mr Fairly of Fairly recommended a plan, which has been almost universally adopted, of granting leases with the most rigid restrictive articles, prescribing a particular course of operations to be followed in the management of every farm, under the penalty of heavy additional rents to be imposed for every deviation however slight. According to his scheme, every farm is divided into three parts, and the tenant is bound not to plough more than a third in any one year, and not to plough the same land more than three years successively. The series of crops is also specified. By these regulations, all the land must rest six years in grass before it can be ploughed a second time. In some places only a fourth of the land is permitted to be in tillage at a time, and only two successive crops are allowed to be taken. The leases are generally granted for 15 or 18 years.

So long as this practice continues, there can be little encouragement to intelligent farmers to embark in an undertaking, in the course of which they must often be constrained to act in opposition to their own judgment. There is no scope left to the exertion of ingenuity, and the most obvious improvements are interdicted by an authority equally arbitrary and injudicious. It is absolutely impracticable to devise a mode of cultivation which will be applicable to every variety of soil; and we can scarcely conceive any system less adapted than this to the clayey soils, which cannot be meliorated without frequent renovation by the plough.

The improvements in agriculture are consequently found to be much fewer than might have been expected, if a more liberal system had been pursued by the landed proprietors. The land is neither sufficiently drained nor cleaned. Many of the antient clumsy practices are still in use. Four horses may be seen dragging an old fashioned plough; or more frequently three horses, with a driver. We have, in several instances, (as lately as April 1810.) witnessed the phenomenon of a plough drawn by two horses, and managed by two men, one holding and another driving. We will not venture to divine what can be the pretence for employing these supernumeraries. On many of the lands, the ridges are still high, broad, and crooked, and the furrows filled with a profusion of rushes. In the neighbourhood of some of the populous towns a better system prevails. The most approved alternate husbandry has been partially introduced, and the lands are let at high rents. Small inclosures sometimes draw from 8*l.* to 10*l.* per acre. The more general rent for arable farms in favourable situations, is at the rate of 2*l.* or 3*l.* per acre. The great abundance of lime is an advantage which is possessed by this county more than almost any other.

Considerable attention has long been bestowed on the rearing of cattle. In Carrick, the Galloway breed has long been esteemed the best for fattening easily, and the beef is allowed to be superior to that of most other species. In Cunningham and Kyle, the Dunlop breed is preferred, as yielding the best milk. The cheese called Dunlop, originally introduced in the parish of that name, is in great repute, and bears a high price throughout all Scotland. The hills in Carrick, and part of Kyle,

afford excellent sheep pasture; and great pains have been taken to improve the breed. In ancient times the sheep of Carrick were celebrated for the fineness and whiteness of their wool. The cultivation indeed appears to have been better formerly than of late. Ayrshire, three centuries ago, was one of the few counties that produced wheat and whisky.

We cannot bestow great praise on the mode in which the land is inclosed and subdivided. With regard to planting, though much has been done, we have already expressed our regret, that there should be such a predilection in favour of the Scotch fir, a species of wood neither pleasing nor profitable, the predominance of which tends to deform many fine tracts of country, which it was intended to beautify as well as to shelter. We may here observe also, that the roads in general are by no means good: they are too narrow, and often carried along the very worst lines; but what is still more inexcusable is, that, though the materials are every where found in great plenty, the roads are kept in very bad repair.

The most important minerals found in Ayrshire, are, 1. Coal, which abounds in almost every parish, and which is wrought in vast quantities in the vicinity of all the towns, especially near the coast. The quantity exported exceeds 100,000 tons annually. 2. Limestone and marl also abound,—the former, however, in the greatest number of places. A considerable quantity is likewise brought as ballast from Ireland. 3. Iron-stone is found in different parts of Carrick, and in the higher parts of Kyle towards the source of the Ayr. At Glenbuck, more than 2000 tons of pig iron are made annually; and a much greater quantity at Muirkirk. 4. Freestone is also found in many places throughout the county. 5. Lead has been discovered in considerable quantity, and mines were opened several years ago in the parish of New Cumnock. The other minerals are copper ores, plumbago, barytes, crystals of zeolite, gypsum, agates, and what is called *water of Ayr stone*, which is in high estimation among cutlers.

The principal towns in Ayrshire, are the boroughs of Ayr and Irvine,—Kilmarnock, Saltcoats, Stewarton, Catrine, Mauchline, Muirkirk, Maybole, Girvan, Beith, Kilwinning, Ballantrae, &c.

Irvine and Saltcoats, though eight miles distant, are considered as the same port. The number of vessels is 90; the tonnage 6774; the seamen 507. The coal exported amounts at an average to 42,000 tons. The imports are almost every species of Irish produce, particularly about 10,000 quarters of grain yearly. The chief foreign import is timber from America, since the Baltic trade has not been regularly open. The trade of Saltcoats is about one-third of the whole. The population of Irvine is about 5000; that of Saltcoats about 3000.

Kilmarnock, the largest town in Cunningham, has long carried on manufactures of carpets, woollen cloths, leather, shoes, and gloves, to a great extent. The annual amount is not less than 100,000*l*. The population is about 10,000. An academy has been lately formed here, which is attended by nearly 400 young people. At Catrine, 15 miles up the river Ayr, very extensive cotton-works were erected some years ago by Mr Alexander of Ballamyle, and Mr Dale of Glasgow. The population is between 2000 and 3000. The process of weaving is carried on in some of these works by the

steam engine; and spinning is executed by water machinery.

Girvan is a small sea-port, the trade of which is very inconsiderable. Stewarton was formerly engaged chiefly in the manufacture of bonnets; and Kilwinning deserves to be mentioned as the birth-place, or rather the nursery, of free-masonry in Scotland.

In the neighbourhood of Muirkirk, there are two sets of iron-works, and also manufactures of coal tar, lamp black, brown paint, &c. Among the improvements which have been projected of late years, there are two which claim particular notice, the canal and harbour of ARDROSSAN, and the harbour of the Troon, with a railroad from Kilmarnock, &c.

The bay of ARDROSSAN, to the north of the port of Saltcoats, is formed by nature. (Mr Telford has remarked in his Report,) as a complete harbour for all the purposes of safety. It possesses many peculiar advantages for communication with Ireland and America, as well as the Baltic; and the canal might be expected to place it in the same situation with respect to Glasgow, which Liverpool holds in relation to Manchester. Mr Telford's proposal was, to convert a space of 300 yards in length, and 100 yards in breadth, into a wet dock, to hold 16 feet depth of water; the length of the south pier to be 600 yards, and that of the north pier 350 yards; the wet dock to contain from 70 to 100 vessels; and the canal to enter at the north-east extremity. The expense of the harbour was estimated at 40,000*l*. The south wall is now finished. Few tide-harbours possess equal advantages, in point of outlet to the sea, facility of entrance, conveniency for anchoring, and security to shipping. But it cannot be expected, that the trade of Glasgow will soon come into this harbour, much less that any other trade, to the extent calculated, is likely to open. The new village of Ardrossan possesses excellent baths, and promises to become one of the best watering places in Scotland.

The Troon Point, between Ayr and Irvine, is one of the finest natural harbours on the west coast, and was long found a convenient station for the smuggling trade. About the beginning of the last century, it is said that the merchants of Glasgow applied to the then proprietor for a feu of the lands adjacent to this spot; but the offer was rejected, from a dread that the price of provisions would be raised by the increase of population, in the event of a harbour being erected. The present Duke of Portland, actuated by more enlightened views, has lately obtained two acts of parliament, the one for forming a harbour at the Troon, and the other for making a railway from the Troon to Kilmarnock. A new pier is constructing, which is to extend from the rock, nearly at right angles, to the distance of 800 feet, where the depth is 19 feet at low water. In the course of this year (1810) 300 feet will be completed. The railroad is advancing rapidly; and it is now proposed that a branch of it shall communicate with Irvine.

Throughout every part of Ayrshire many vestiges of antiquity may be traced, as cairns, encampments, druidical circles, &c. The castles at one time must have been very numerous. The remains of a few are still visible, as of Loch Doon, Denure, Greenan, Mauchline, Turnberry, Auchinleck, Barr, Dean, Dundonald, Cessnock, Kirrila, Knock, Fairly, Skelmurly, Barbiston, Sundrum, Cumnock, Ardrossan, Cassilis, Thomaston.

&c. There were also many religious houses, as—the abbey of Kilwinning, founded in 1140; Crossraguel, in 1244; Failand, a monastery, in 1252; Feale, a priory; Mauchlin, an abbacy, founded by David I.; Dalmulin, a monastery, founded by Walter II. Steward of Scotland; Ayr 1230, and another 1472; Irvine, 1412; Munniboil, (Maybole), a collegiate church, in 1441; Kilmaurs, in 1403, &c.

The most ancient families in this county are said to have been Auchinlecks, Blairs, Boyds, Boswells, Campbells, Cathcarts, Cochranes, Craufurds, Crichtons, Cunninghams, Dalrymples, Dunlops, Fullartons, Hamiltons, Kennedys, Lindsays, Montgomerics, Stuarts, Wallaces.

Few parts of the country have undergone greater vicissitudes than this. With regard to the aborigines, it can scarcely be doubted, that the Selgovæ, Novantes, and Damii, who, at the time of the Roman invasion, possessed the peninsula between the Solway and the Clyde, were of British descent. These tribes formed part of the province of Valentia, which submitted to the yoke of the conquerors, while the Caledonians, to the north of Antoninus' wall, maintained their independence. The Damii appear to have inhabited Ayrshire, or at least the northern part of it, although the whole tract of country, including ancient Galloway, Carrick, Kyle, and Cunningham, has sometimes been called the Chersonesus of the Novantes. After the abdication of the Roman government, this territory is described as an independent principality, known by the name of the Cambrian, or Cumbrian kingdom, sometimes less correctly denominated the kingdom of Stathcluyd. During the Saxon heptarchy, Galloway, including the southern division of Ayrshire, was infested and over-run by the Northumbrians; and to this period we may perhaps refer the origin of certain Saxon names and usages, as well as some superstitious notions, which are scarcely yet eradicated, and which are evidently relics of the Anglo-Saxon mythology. Thus Kirkoswald, in Carrick, according to tradition, owes its name to Prince Oswald, to whom, also, Kirkoswald in Northumberland traces its foundation; and at both places certain customs are still prevalent, which must be ascribed to one common source. The elfin race, who have so long haunted the banks of the Girvan and the Garpal, and who, to this hour, are said to be performing their capricious freaks in the precincts of Crossraguel's ruined abbey, are well known to be of Saxon pedigree. In the eighth century, the Saxons extended their ravages to Kyle and Cunningham, and established a colony in that province. These intruders, aided by the Picts, reduced the metropolitan city of Alcluyd, and enjoyed a short-lived tranquillity in their usurped possessions. The Scots of Ireland and Argyle did not permit them long to rest. Early in the ninth century, the sanguinary and rapacious Alpin sailed from Cantire, and made an unexpected descent on the coast of Kyle. His savage followers spread devastation every where around; but his progress was suddenly checked by some of the native warriors; and the invader fell, at a spot near the source of the Doon, afterwards distinguished by the name of Laicht-Alpin, where, as the etymology suggests, a flat and ponderous stone was placed to mark his grave. Kenneth Mac-Alpin was more successful in his incursions on the western shores; but though his forces effected settlements in these regions, and though emigrants from Ireland, at

different periods, colonised spacious portions of the same territory, and gave the name of Galloway to the whole extent of country from the south of Annandale to the north of Ayrshire, it is not ascertained that the Saxons were either exterminated or altogether dislodged: On the contrary, there can be little doubt, that many of the present inhabitants of Ayrshire are of Saxon extraction, and that the numbers of that lineage were reinforced by the crowds of English refugees who fled from the sword of the Norman conqueror, during the reign of Malcolm Canmore. The promiscuous race of Britons, Saxons, Scots, and Picts, who occupied this part of the country, were frequently infested by the Danes, or Norwegians; and tradition still points out the traces of many hard fought battles, in which the invaders were discomfited with immense slaughter. The last and fiercest of these encounters is said to have taken place at Largs, in 1263, when the host of Norway was routed by the Scots; but the glories of that bloody day have been prodigiously exaggerated by our national chroniclers. A more obstinate foe from the south afterwards made encroachments on this devoted province, which was kept in perpetual agitation and alarm, during the alternate successes and reverses of Wallace and Bruce. The English kept possession of the strong fortresses long after the whole of Ayrshire had been steadily devoted to the cause of Bruce, the earl of Carrick. After the fatal battle of Durham, (1346.) the victorious troops of England again penetrated into the heart of this county, carrying devastation and terror wherever they went. During the next 200 years, the hostile visits of our southern neighbours seldom reached so far; but this part of the land was sufficiently harassed with domestic turbulence. While the feuds of rival chieftains were reducing the population, superstition was erecting her gloomy temples, and ecclesiastical authority was boldly appropriating the inheritances of the destroyers and the destroyed. The improvement of the people was little consulted by the inmates of these consecrated edifices, reared with the price of blood, and supported by the oblations of guilt; and yet, it must be confessed, that the arts which the churchmen introduced, and the efforts which they made to embellish and fructify the country, had a tendency to open the minds, and polish the manners, not only of the great, but even of the middle and lower orders. At a later period, some of the chief families of Ayrshire acted a conspicuous part in forwarding the Reformation: an undertaking in which none engaged with greater keenness than those who had the best opportunities of witnessing the haughtiness and luxury of the Catholic clergy, and those who had the fairest prospect of succeeding to a share of the opulence which they had envied, and the power which they had feared. In Ayrshire, the revenues of some of the abbeys were prodigious; and the dissolute manners of the ecclesiastics kept pace with their enormous wealth and patronage. The antipathy to this spiritual despotism continued, during the succeeding age, to operate with unabated force, all over the west. The severe and impolitic measures which were taken, soon after the Reformation, with a view to extinguish the presbyterian spirit, were such as could not fail to impress the non-conformists with a rooted abhorrence to the principles of their persecutors, and to alienate them for ever from the house of Stuart. While the toleration which they had experienced from the usurper Cromwell, whose

victorious armies had quietly occupied their coasts, was still fresh in their recollection, an armed banditti from the Highlands were let loose, by the unenlightened agents of the monarchy, to suppress conventicles, and enforce uniformity of religion. This barbarous militia, regardless equally of the dictates of humanity and piety, committed unheard of atrocities; and the loss sustained in this county from their depredations, amounted, in the year 1678, to 137,500*l.* Scots. Since the Revolution in 1688, the inhabitants have been tranquil and loyal in the most turbulent times.

The yeomanry and peasantry are, in general, a handsome, athletic, and industrious set of people, correct in their morals, frugal in their habits, and zealously attached to the civil and ecclesiastical constitution of the country. The manufacturing towns are inhabited by persons of a more miscellaneous description. The patrician families, many of whom claim alliance with the most illustrious names in Scottish history, evince a strong partiality to the county with which they are connected, and are said to be tenacious of aristocratical ideas, to a greater degree than almost any of the other nobility in the lowlands. Hitherto the middle and lower ranks have rarely been betrayed into the sectarian spirit which pervades some other counties. Of late years, indeed, the number of dissenters has increased considerably in the populous towns and villages; but their separation from the church is attended by no violent symptoms of disaffection. Their pastors, so far as we have an opportunity of knowing, are men of liberal and rational views, untainted with bigotry, and, in promoting every pious and benevolent purpose, cordially disposed to cooperate with their brethren of the established church; whose respectability and diligence are such, that the great mass of the population adhere to their ministry from affection as well as from principle.

In former times there was much smuggling on this coast; and those who engaged in it carried on their operations in such formidable bodies, that a military force durst scarcely venture to attack them with an equality of numbers. The dissolution of morals, fostered by this illicit traffic, was here confined within a limited range; but it is happy for the country that these adventurers are now almost extinct.

The above account has been necessarily abridged. We have received several interesting communications on the subject, of which our limits do not permit us to avail ourselves. No agricultural survey of the county has hitherto been printed, except one by Colonel Fullarton in 1793. It is understood, that Mr Aiton, writer in Strathaven, is employed in preparing a report on this and some other counties. Some information, though none of a later date than 1800, may also be expected from the third volume of Chalmers's *Caledonia*, (not yet published.) See CATRINE, IRVINE, KILMARNOCK, MURKIRK, SALTCOATS, and TROON.

AZAB, the *Saba* of the ancients, a territory in Abyssinia, situated on the east coast of the Red Sea, which was probably one of the principal stations of the caravans that traded to Arabia. The inhabitants were formerly called Sabæi, and it was famous for frankincense, myrrh, and aromatic plants. Near Azab are the remains of an aqueduct, built with huge blocks of marble, kept together with bars of brass instead of cement, and also of a number of walls constructed with pieces of marble in a similar manner. Azab was probably the residence of the

queen of Saba. See *Strabo*, lib. xvi.; *Leod.* lib. iii.; and Bruce's *Travels*. (j)

AZALEA, a genus of plants of the class Pentandria, and order Monogylia. See BOTANY. (x)

AZIMUNTINES, the inhabitants of Azimuz, or Azimuntum, a city of Thrace. See Gibbon's *Hist.* chap. xxxiv. vol. vi. p. 54.; chap. xlvi. vol. viii. p. 183. (w)

AZIMUTH, in Astronomy, an Arabic word, employed by astronomers to denote the arc of the horizon intercepted between the meridian and a vertical circle passing through the celestial body whose azimuth is measured.

Let it be required to find the sun's azimuth at Greenwich, the sun's declination being 21° 40', and his altitude 48° 20'. We have

Complement of latitude	38° 32'
Complement of altitude	41 40
Complement of declination	68 20
<hr/>	
Sum	148 32
Half sum	74 16
Complement of latitude, subtract	38 32
<hr/>	
First difference	35 44
<hr/>	
Half sum	74° 16'
Complement of altitude, subtract	41 40
<hr/>	
Second difference	32 36
Then,	
Co. arith. of sine of co. lat.	38° 32' 0.2055330
Co. arith. of sine of co. alt.	41 40 0.1773117
Sine of first difference,	35 44 9.7664229
Sine of second difference	32 36 9.7314040
<hr/>	
Sum of the logarithms	19.8806716

Sine of the half sum is 60° 39' 9.9403358. Double of this is 121° 18', the sun's azimuth from the north, the complement of which to 180° is 58° 42', the sun's azimuth from the south. (a)

AZINCOURT. See AGINCOURT.

AZOF, a town and fortress in Cuban Tartary, belonging to Russia. It is situated on the southern shore, and near the mouth of the river Don; and is supposed to be the same with the ancient Tana. This town, according to Strabo, was built by the Bosporanian Greeks, and was considered a place of great trade; but little is known of its history till 1473, when we find it in possession of the Genoese, who soon after resigned it to the Turks. During the succeeding wars between the Turks and Russians, Azof was alternately lost and won by these powers, till by the treaty of Belgrade, it was agreed that the fortifications should be demolished, and the town remain subject to Russia. In this state it continued for 30 years: when, in the last wars with the Turks, the fortifications were rebuilt by the order of Catharine II. and this town is now in the best possible state of defence. Its consequence, however, as a port of trade, has been of late rapidly declining; and the arm of the Don, on which it lies, is gradually filling with sand. Population 3800. N. Lat. 47°, E. Long. 39° 14'. (b)

AZOF, SEA OF, known also by the name of the Zambache Sea, lies in the dominions of Russia, and communicates with the Euxine by the straits of Caffa. Its

principal harbour is Taganrok, which carries on a considerable trade with the Crimea, and the maritime towns of Natolia. The whole of the northern coast is laid out in fisheries. The fish, in general, are small, but so abundant, that 60,000 are often taken at one draught. A remarkable circumstance of the emersion of an island in the sea of Azof, has been lately announced by M. Palas, the celebrated naturalist. On the 5th of September 1799, this island suddenly made its appearance, at the distance of 150 fathoms from the shore. The phenomenon was preceded by a noise like thunder, and accompanied with an eruption of smoke and flames, the explosion of which resembled the discharge of heavy ordnance; at the same time, a violent shock of an earthquake was felt from Cuban as far as Carinodan. The sea of Azof is 210 miles in length, and from 40 to 60 in breadth. N. Lat. $45^{\circ} 20'$ to $47^{\circ} 20'$, E. Long. $34^{\circ} 30'$ to $39^{\circ} 30'$. See TOOKE'S *View of the Russian Empire*. (p.)

AZORES, TERCEIRAS, or WESTERN ISLES, are a group of islands lying in the Atlantic Ocean, about 800 miles west of Cape St Vincent, and almost at an equal distance from Europe, Africa, and America. They are discovered from a great distance at sea, on account of a high mountain, called the Peak, or Pico, in an island of the same name, and which Mr Pinkerton strongly recommends to geographers to assume as a first meridian of longitude. The Azores are nine in number, Terceira, St Michael, Santa Maria, Graciosa, St George, Fayal, Pico, Flores, and Corvo, of which the two last are very small, and lie at a considerable distance from the rest. Concerning the history of these islands, little is known with certainty. Their discovery has been claimed by the Portuguese, though the precise period has not been determined. It has, however, been maintained, that they were first visited by Joshua Vanderberg, a merchant of Bruges, who, when on a voyage to Lisbon in 1439, having been driven from his course in a violent storm, fell in with the Azores, and called them "The Flamingas," or Flemish Islands. Communicating the intelligence to his friends at Lisbon, he gave such an account of his adventure, as induced the Portuguese, who were then the most enterprising nation in Europe, to attempt a farther discovery. Having successively explored the different islands, Don Henry, prince of Portugal, was so pleased with the acquisition, that he went in person to take possession of them in 1449. In 1466, Alphonso V. gave them to his sister the Dutchess of Burgundy, when some of them were colonized by Germans and Flemings. These, however, seem always to have acknowledged the authority of Portugal. At present a Portuguese governor resides at Angra, the chief city of Terceira. In spiritual affairs they are under the jurisdiction of the bishop of the Azores, whose capital residence is in the island of St Michael.

The Azores have frequently suffered severely from earthquakes and volcanic eruptions; and from the geological history of these islands, it would appear that some of them must have owed their origin to these terrible convulsions of the earth. Kircher affirms, that in 1538 frequent earthquakes were felt for nearly eight days, which were so violent as to compel the inhabitants to forsake their houses, and lie night and day in the open fields. On the 26th June, a fire burst through the surface of the sea, flaming to the clouds, vomiting prodigious quantities of sand, earth, stones, and minerals;

and raging with such fury, that, had not the wind blown from the land, the whole of the neighbouring islands would have been destroyed.

This was followed by the emersion of a group of rocks which at first filled a space of only five or six acres, but which soon extended to as many miles. Another shock of an earthquake broke them in pieces, and then united them into a solid mass, which now forms one of the small islands that lie on the north-west of the Azores. See Kircher's *Mundus Subterraneus*, lib. ii.

In 1720, another island, all fire and smoke, which roared like thunder, appeared between St Michael and Terceira, on the night of the 20th November. The bursting out of the flames was attended by an earthquake, which shattered many of the houses in Terceira, and, for many leagues round the island, astonishing quantities of pumice stone, and half-broiled fish, were found floating on the sea: (*Phil. Trans.* vol. xxxii. p. 100.) This island, however, has since disappeared. The consequence of another furious earthquake, which occurred July 9, 1757, and which shook the neighbouring islands to their foundation, and covered them with ruins, was the production of eighteen small islands about ten yards from the north coast of St George's, which, however, subsided again in a few months.

On the 1st of May 1808, a new volcano made its appearance in the island of St George. The fire burst out in a ditch in the midst of fertile pastures, three leagues south-east of Vellas, and immediately formed a crater in size about 24 acres. It raged with great fury for two days, and the cinders which it threw up, being propelled by a strong north-east wind, covered the ground from one to four feet in depth for half a league in breadth, and three leagues in length, and then passing the channel about five leagues wide, were driven upon the east point of Pico. The fire had nearly subsided in the evening of the 2d, when a smaller crater opened a league nearer Vellas. Its mouth was only about 50 yards in circumference. The fire seemed struggling for vent; and the force with which a pale blue flame issued forth, resembled a powerful steam-engine multiplied a hundred fold. The whole island was convulsed; earthquakes were frequent, and horrid bellings were occasionally heard from the bowels of the earth. This was followed by 12 or 15 small volcanoes which broke out in the neighbouring field, but they all subsided on the 11th, when the large volcano, which had lain dormant for nine days, burst forth with more tremendous force, and continued to rage until the 5th of June, when it began to fail, and a few days after it entirely ceased.* Its horrid belchings were distinctly heard at 12 leagues distance, and the immense quantity of lava which it vomited, overwhelmed in its course farms, cattle, corn-fields, and vineyards; and swept the town of Ursulina from its foundation. Though it gave timely notice of its approach, many of the inhabitants, by remaining too long in its vicinity, endeavouring to save their effects, were so dreadfully scalded by flashes of steam (which without injuring their clothes took off not only their skin, but their very flesh), that several of them died upon the spot. About sixty suffered in this miserable manner; and so great was the anxiety and consternation which seized upon the people, that they entirely abandoned their domestic concerns, and were in danger of starving in the midst of plenty. This

* The elevation of the crater is about 3500 feet, and its distance from the sea about four miles.

island, heretofore rich in cattle, corn, and wine, is nearly ruined; and a scene of greater desolation and distress has seldom been witnessed in any country. See the *Christian Observer*, vol. vii. p. 743.

The Azores are subject also to violent winds, and frequent inundations of the ocean, which often overwhelm the houses, and sweep from the fields the flocks and grain. They are, however, extremely fertile, and produce corn, wine, and fruits, in great abundance. There is an annual exportation of 20,000 pipes of wine; and the single article of tobacco affords a considerable revenue to the king of Portugal, who claims a tenth of all

the productions of these islands. The air is wholesome, and the sky is in general clear and serene. No poisonous or noxious animals breed on the Azores, and, it is said, that if carried thither, they will expire in a few hours. N. Lat. 36° to 49°, W. Long. 25° to 35°. See Adanson *Voyage au Seneegal*. Pinkerton's *Geography*, vol. i. p. 601. (f)

AZOTE, or NITROGEN, the *phlogisticated air* of Priestley, was discovered by Dr Rutherford in 1772. It constitutes 4-5ths of atmospheric air, the other 5th being oxygen. See CHEMISTRY. (j)

B.

BAAL, or BEL, a word of Hebrew origin, denoting *ruler*, was the name by which several of the eastern nations worshipped the solar fire, which they supposed to be the governing principle of the universe. At first, indeed, this appellation seems to have been given to JEHOVAH. But as idolatry began to prevail, and the supremacy of the true God to be forgotten, his attributes were ascribed to those objects in nature whose appearance was most splendid and overpowering, or whose influence was most sensibly felt. The sun, accordingly, became an object of general adoration, and was supposed to hold the highest rank among those divinities with which the wild imaginations of eastern idolators had peopled the heavens. The author of the Phœnician theology, which has been preserved in the writings of Eusebius, informs us, "that the Phœnicians supposed the sun to be the only Lord of heaven, styling him *Bael-samen*, which, in their language, signifies *Lord of heaven*." A *beave* or *bull* was the emblem of this divinity; and as this idol was represented in different places with various insignia, hence arose the denominations, Baalberith, Baal-gad, Baal-moloch; and these diversified *Baals*, says Parkhurst, seem to be what the Scriptures call in the plural *Baalim*. There can be no doubt, however, that the appellation Baal was not always restricted to the sun, but was frequently given to those distinguished personages, who, in different nations, were exalted for their achievements to the rank of deities. Among the Phœnicians, in particular, there were several divinities besides the sun honoured with this name. BAAL, BEL, or BELUS, was the principal god of the Carthaginians, Sidonians, Babylonians, and Assyrians; and as he was supposed to delight in human sacrifices, he was probably the same as the Moloch of the Ammonites, the Κρόνος (*Chronus*) of the Greeks, and the Saturn of the Latins.

High places were always chosen for the temples and altars of Baal, in which was preserved a perpetual fire. His priests and prophets were extremely numerous; and the manner in which they conducted the worship of their god was at once frantic and ferocious. While the victims smoked on the altar, they danced round it with the most violent gesticulations, cut their bodies with knives and lancets, and raved and prophesied as if immediately under the inspiration of Baal. Bel, Bal, or Beal, was likewise the name of the principal deity of the ancient Irish, derived, according to Vallancy, from the Punic mythology. On the tops of many hills

in Scotland there are heaps of stones, called by the vulgar, Bel's Cairns, where it is supposed sacrifices were offered by our Pagan ancestors. See Eusebius, *Preparat. Evange.* lib. 1. cap. 10. 2 *Kings* xxiii. 5. *Collectanea de Rebus Hibernicis*, vol. 2. p. 263. And Parkhurst's *Lexicon*, article . (u)

BAALBEC. See BALBEC.

BABAHOYA, the name of a town and district of Guyaquil, in South America. Rice, cotton, Guinea pepper, and a variety of fruits, are among the productions of this district. (j)

BABEL, a tower, built by the posterity of Noah after the flood; remarkable for its great height, and for the disappointment of the builders, by the confusion of their language, (*Gen.* xi. 1—9.) The land of Shinar, in which the posterity of Noah settled, lay along the river Tigris, from the mountains of Armenia to the junction of the Tigris and Euphrates; and the plain of Shinar, where the tower was built, was undoubtedly the place, or near to the place, where the famous city Babylon afterwards stood; upon the banks of the great river Euphrates, and not far from its junction with the Tigris. Josephus, and some others, ascribe this great design to Nimrod; but, although it might correspond very well with the character which Scripture has given of that enterprising prince, yet Bochart (in his *Phaleg.* lib. i. cap. 10.) has shewn, that Nimrod was either not born, or was very young, when this tower was built. But there is no doubt, that Nimrod and his subjects did afterwards settle at Babel, and there built Babylon, which became the capital of the Assyrian empire. It has also been a common opinion, that Shem and his posterity had no hand in this great undertaking; but, from the Mosaic history, it seems perfectly clear, that the whole human race were actually engaged in it. Its date is differently computed, according as chronologers follow the LXX interpreters, who make it 531; the Samaritan copy, which makes it 396; or the Hebrew, which allows it to be no more than 101 years after the flood. It is believed to have been about the time of the birth of Peleg; for in *Gen.* x. 25. we read, that "unto Eber were born two sons, and the name of the one was Peleg;" which being derived from a Hebrew word signifying to *divide*, the reason why that name was given to him is added, "for in his days was the earth divided." From the account given of Peleg's ancestors, in the subsequent chapter, it appears, that he was born in the 101st year after the flood; though the confusion of the language of the

builders, and their consequent dispersion, might not take place for many years afterwards.

Its dimensions, as given by ancient historians, may be deemed suitable for a building, which seems to have been designed to be the palace, or citadel, of the empire of the world. The Scripture tells us, that it was built of burnt bricks instead of stone, and of slime instead of mortar. According to an ancient tradition, three years were employed in making the bricks; each of which was thirteen cubits long, ten broad, and five thick; and they were cemented by bitumen, or a pitchy substance, of which, according to Herodotus, great quantities are to be found on the banks of the river Is, in the neighbourhood of Babylon. When some eastern writers tell us, that this tower was no less than twelve miles high, the assertion refutes itself. Even the affirmation of St Jerome, (though he rests it upon the testimony, as he says, of eye-witnesses,) that its ruins were four miles high, is as little worthy of credit. If the opinion of the learned Bochart be correct, that the tower in the temple of Belus in Babylon is the same with the tower of Babel, the description which Herodotus has given of the former, is applicable to the latter. He tells us, that it was a square tower, built in the form of a pyramid; each side of which, at its base, measured a furlong: and its height, according to Strabo, was also a furlong, or 660 feet; exceeding, by 60 feet, the highest of the pyramids of Egypt, according to the late measurement of these stupendous monuments of antiquity by the French. Around the outside of the building, there was a winding passage from the bottom to the top, and so very broad as to permit carriages to pass each other; which gave it the appearance of eight square towers, built one above another, and gradually decreasing in size to the top of the building. It contained many large rooms, with arched roofs supported by pillars; these became parts of the temple of Belus, after it was converted into a place of idolatrous worship; and, in the highest tower, there was an observatory for astronomical purposes, a science in which the Babylonians eminently excelled.

Several descriptions of the state of this famous tower in later times, may be found in the *Anc. Un. Hist.* vol. i. p. 354. A traveller, who saw it not many years ago, describes it in these words: "Four gentlemen of our party and myself went to view the tower of Nimrod. After travelling through exceedingly high reeds and rushes, and a very dangerous road, in about two hours we came to the tower, which is built on an eminence, and a base of about 100 cubits diameter. It appears almost like a mass of earth, being erected of bricks dried by the sun, amazingly thick, and betwixt every three or four feet there is a layer of reeds; its height is at least 160 feet, but we found no remains either of a door or stairs. The only curiosity, which struck us, was the astonishing freshness of the reeds, which seemed as if put in but a very few years ago, though, by the best accounts we could find, it has been built upwards of 4000 years." *Journey from Bassora to Bagdad by a Gentleman in 1779*, p. 59.

Various have been the conjectures respecting the reason which induced the whole human race to unite, as one man, in this great enterprise. Some have supposed, that their design was to raise a tower so high as to enable them to climb up into heaven; a strange opinion, founded upon a literal interpretation of these words in Scripture, "Let us build a city, and a tower whose

top may reach unto heaven;" an expression evidently intended to signify no more than that its height was to be uncommonly great. Similar expressions are to be found in Deut. i. 28, and ix. 1. where the cities of the heathen nations, who inhabited the land of Canaan, are described as "great, and walled or fenced up to heaven." Nor was it uncommon for the Greek poets to use the expressions, "high as heaven," or "reaching to the sun," when they wished to describe things of an extraordinary height. Josephus, and some others, have thought that it must have been designed to preserve them from a second deluge, which they greatly dreaded: but, had that been the case, they would have betaken themselves to the mountains, and not made choice of the low country, for building a place of security. A third opinion is, that, as the tower was in the form of a pyramid, to the figure of which the flame of fire bears a resemblance, it was a monument designed in honour of the sun, to whose influence they ascribed the drying up of the flood. But there is no foundation in Scripture for that conjecture, and the date of that species of idolatry was probably not so early as it supposes. The reason assigned in Scripture is, "Let us make us a name, lest we be scattered abroad upon the face of the whole earth." The most probable conjecture, therefore, seems to be, that, as they were now in a vast plain, undefined by buildings, or roads, or any distinct boundaries; and as they must soon separate to attend to their flocks, or go in quest of provisions; or, perhaps, dreading a dispersion, in consequence of Noah's projected division of the earth among his posterity;—they built this tower, as a *pharos*, or landmark, to enable them to find their way back to the surrounding city; which, with its immense tower, they believed would be a lasting monument of their fame, and transmit their name with honour to posterity. In that view, their design had been to make the whole world one kingdom, and Babel its metropolis.

This interpretation seems also to account for the reason of the divine frustration of their great design, and of their consequent dispersion. It is given in these words, "Behold the people is one, and they have all one language, and this they begin to do, and now nothing will be restrained from them which they have imagined to do," that is, not as some have explained the words, if this scheme shall succeed, the divine plan for the government of the world will be frustrated; but, as the words more naturally signify, this their first attempt, and if they succeed in it, they will think themselves able for any undertaking,—no enterprise will appear too great for them. Accordingly, the very dispersion which they dreaded, they brought upon themselves, by their vain attempt to avoid it. "The name of it was called *Babel*, because the Lord did there confound the language of all the earth, and from thence did the Lord scatter them abroad upon the face of all the earth." See *Anc. Un. History*, vol. 1. Stackhouse's *Hist. of Bible*, vol. 1. Stuckford's *Connection*, vol. 1. (A. F.)

BAB-EL-MANDEB, or **BAB-EL-MANDEL**, the name of a cape and straits at the entrance into the Red Sea. The straits are divided by the island of Perim, which is perfectly flat, and about three miles from the cape. A bay to the eastward of the cape extends inwards a considerable way, and the land between it and the bay on the west, is a dry salt sand, and so perfectly flat, that if the sea were to rise only a few feet it would cover it. Part of it is already a lake of salt water. Accidents

have sometimes arisen, from mistaking this eastern bay for the strait. These might be avoided, by keeping Perim close on the larboard side, and by observing that Bab-el-mandeb hill is the highest land in the neighbourhood. In lord Valentia's chart of the Red Sea, the breadth of the straits of Bab-el-mandeb is only 15 British miles. East longitude of the cape $43^{\circ} 33'$, North latitude $12^{\circ} 40'$. See Niebuhr's *Travels*, Bruce's *Travels*, Vincent's *Percyplus*, and lord Valentia's *Travels*, vol. ii. p. 13, 14. (o).

BABOON, in zoology, a subdivision of the *ape* tribe, distinguished from their congeners in having a facial angle of about 30° , cheek-pouches, callosities on their posterior, and either no tail, or one that is very short. See **SIMIA** and **MAMMALIA**. (f)

BABYLON, CITY OF, the capital of the ancient kingdom of Babylonia, is supposed to have been situated in N. Lat. $32^{\circ} 34'$, and in E. Long. $44^{\circ} 12' 30''$. It was founded by the first descendants of Noah, 2234 years B. C., enlarged by Nimrod, the great grandson of Noah, 2000 years B. C., and in a manner completely rebuilt about 1200 years B. C. by the Assyrian queen Semiramis. It was greatly strengthened and beautified by various succeeding sovereigns: but it was by Nebuchadnezzar and his daughter Nitocris, that it was brought to such a degree of magnificence and splendour, as rendered it one of the wonders of the world.

Babylon stood in the midst of a large plain, in a very deep and fruitful soil. It was divided into two parts by the river Euphrates, which flowed through the city from north to south. The old city was on the east, and the new city, built by Nebuchadnezzar, on the west side of the river. Both these divisions were enclosed by one wall, and the whole formed a complete square, 480 furlongs in compass. Each of the four sides, of this square had 25 gates of solid brass, at equal distances; and at every corner was a strong tower, ten feet higher than the wall. In those quarters, where the city had least natural defence, there were also three of these towers between every two of the gates; and the same number between each corner, and the nearest gate on its two sides. The city was composed of fifty streets, each 15 miles long, and 150 feet broad, proceeding from the 25 gates on each side, and crossing each other at right angles, besides 4 half streets, 200 feet in breadth, surrounding the whole, and fronting towards the outer wall. It was thus intersected into 676 squares, which extended four furlongs and a half on each of their sides, and along which the houses were built, at some distance from each other. These intermediate spaces, as well as the inner parts of the squares, were employed as gardens, pleasure grounds, &c.; so that not above one half of the immense extent which the walls enclosed, was occupied by buildings.

The walls of Babylon were of extraordinary strength, being 87 feet broad, and 350 high. They were built of brick, and cemented by a kind of glutinous earth called bitumen, which had the quality of soon becoming as hard as stone. These walls were surrounded on the outside by an immense ditch, from which the earth had been dug to make the bricks; and which, being always filled with water, added very much to the defence of the city.

On each side of the river Euphrates, was built a quay, or high wall, of the same thickness with the walls around the city. There were gates of brass in these walls opposite to every street which led to the river, and

from them were formed descents or landing places by means of steps, so that the inhabitants could easily pass in boats from one side of the city to the other. There was also a remarkable bridge thrown over the river, near the middle of the city, built with wonderful art of huge stones, fastened together by means of iron chains and melted lead; and is said to have been a whole furlong in length, and 30 feet in breadth.

In order to prevent any inconvenience from the swellings of the Euphrates, two canals were cut from that river at a considerable distance above the town, which carried off the superabundant waters into the Tigris. From the place where these canals commenced down the sides of the river, both above and below the city, immense banks were constructed to confine the stream still more effectually within its channel, and to prevent still more completely all danger of an inundation. In order to facilitate the construction of these works, an immense lake was dug on the west side of Babylon, about 40 miles square, and 35 feet deep, into which the river was turned by a canal, till the banks were completed: and it was then restored to its former course. This lake continued afterwards to receive annually a fresh supply of water from the Euphrates, and was rendered very serviceable by means of sluices for watering the lands which were situated below it.

At the two ends of the bridge over the Euphrates were two magnificent palaces, which had a subterraneous communication with each other, by means of a vault or tunnel, under the bed of the river. The old palace, on the east side, was about 30 furlongs in compass, and was surrounded by three separate walls, one within the other, with considerable spaces between them. The new palace, on the opposite side, was about four times as large as the other, and is said to have been eight miles in circumference. The walls of both these edifices were embellished with an infinite variety of pieces of sculpture; and, among the rest, was a curious hunting scene, in which Semiramis was represented on horseback throwing her javelin at a leopard, while her husband Ninus was piercing a lion.

The most remarkable structure in the new palace was the hanging gardens, which Nebuchadnezzar is said to have raised, in order to give his wife Amylis, (daughter of Astyages, king of Media,) some representation of the beautiful mountainous and woody views which abounded in her native country. These gardens occupied a square piece of ground, 400 feet on every side, and consisted of large terrasses, raised one above the other, till they equalled in height the walls of the city. The ascent from terrass to terrass was by means of steps 10 feet wide; and the whole pile was sustained by vast arches, built upon other arches, and strengthened on each side by a solid wall, 22 feet in thickness. Within these arches were very spacious and splendid apartments, which are described as having commanded a very extensive and delightful prospect. In order to form a proper pavement for supporting the soil, and confining the moisture of the garden, large flat stones, 16 feet in length, and 4 in breadth, were, first of all, laid upon the top of the upper arches; over these was spread a layer of reeds, mixed with bitumen; upon this, two rows of brick, closely cemented; and the whole covered with sheets of lead, upon which the earth or mould was laid to a sufficient depth for the largest trees to take firm root. In the upper terrass was a large reservoir

voir, into which water was drawn from the river by some species of engine, and kept there ready to be distributed to any part of the gardens.

Near to the old palace stood the temple of Belus; and in the middle of the temple was an immense tower, about 600 feet in height, and the same number square at the foundation. This huge pile of building consisted of eight towers, each 75 feet high, placed one above the other, and gradually decreasing towards the top like a pyramid. The ascent to the summit was accomplished by stairs on the outside, in a sloping direction, and of a spiral form; and these, winding eight times round the whole, produced the appearance of as many towers, regularly contracting their diameter. In the different stories were many lofty apartments, supported by pillars, and used as chapels or temples in the worship of Baal; and on the top of all was erected a complete observatory for astronomical purposes. What has been described is understood to have been the old tower of Babel, but it was greatly enlarged by Nebuchadnezzar, who built around its base a number of other sacred edifices, forming a square nearly three miles in compass. The whole was inclosed by a strong wall, and the various entrances secured by solid gates of brass, which are conjectured to have been formed out of the spoils of the temple at Jerusalem. (*Dan.* i. 2.; *2 Chron.* xxxvi. 7.) In this temple of Belus, or, as some say, on its summit, was a golden image 40 feet in height, and equal in value to $3\frac{1}{2}$ millions sterling. There was, besides, such a multitude of other statues and sacred utensils, that the whole of the treasures contained in this single edifice, have been estimated at 42 millions.

Many of the above statements, recorded in ancient authors respecting the wonders of Babylon, are unquestionably greatly exaggerated; but, after every abatement that can fairly be made, this city is understood to have comprehended a regular square, 48 miles in circuit, and to have been eight times larger than London and its appendages. (See Gillies' *Hist. of the World*, vol. i. p. 166. and Rennel's *Geog. of Herodotus*, p. 341.) The city of Babylon seems to have excelled in rich and ingenious manufactures, at a very early period in the history of the world; and its "goodly garments" are mentioned 1450 years before Christ. (*Joshua*, vii. 21. and *2 Sam.* xiii. 18.) For the space of 26 years after the death of Nebuchadnezzar, it continued to retain its glory; and was at once the seat of an imperial court, the station of a numerous garrison, and the scene of a most extensive commerce. It was at length invested, about 540 years before Christ, by the victorious armies of Cyrus the Great. Crowded with troops for their defence, surrounded with such lofty walls, and furnished with provisions for 20 years, the citizens of Babylon derided the efforts of their besieger, and boasted of their impregnable situation. On the other hand, the conqueror of Asia, determined to subdue his only remaining rival in the empire of the eastern world, left no expedient untried for the reduction of the city. By means of the palm trees, which abounded in that country, he erected a number of towers higher than the walls; and made many desperate attempts to carry the place by assault. He next drew a line of circumvallation around the city; divided his army into 12 parts; appointed each of these to guard the trenches for a month; and resolved to starve his enemy to a surrender. After spending two years in this blockade, he was presented with an opportunity of effecting his purpose by stratagem. Having

learned that a great festival was to be celebrated in the city, and that it was customary with the Babylonians, on that occasion, to spend the night in drunkenness and debauchery; he posted a part of his troops close by the spot where the river Euphrates entered the city, and another at the place where it went out, with orders to march along the channel, whenever they should find it fordable. He then detached a third party to open the head of the canal, which led to the great lake already described; and, at the same time, to admit the river into the trenches, which he had drawn around the city. By these means the river was so completely drained by midnight, that his troops easily found their way along its bed; and the gates, which used to shut up the passages from its banks, having been left open in consequence of the general disorder, they encountered no obstacle whatever in their progress. Having thus penetrated into the heart of the city, and met, according to agreement, at the gates of the palace, they easily overpowered the guards; cut to pieces all who opposed them; slew the king Belshazzar, while attempting to make resistance; and received the submission of the whole city within a few hours. From this period Babylon ceased to be the metropolis of a kingdom; and its grandeur very rapidly decayed. Its citizens were very impatient under the Persian yoke; and their pride was particularly provoked by the removal of the imperial seat to Susa. Taking advantage of the disorders in Persia, in consequence of the sudden death of Cambyses, and of the massacre of the Magians, they continued, during the space of four years, to make secret preparations for a revolt. At length, in the fifth year of Darius Hystaspes, about 518 years before Christ, they openly raised the standard of rebellion; and thus drew upon themselves the whole force of the Persian empire. Determined upon a desperate defence, and desirous to make their provisions last as long as possible, they adopted the barbarous resolution of destroying all such persons in the city as could be of no service during the siege. Having sacrificed the lives of their friends, and resolutely regardless of their own, they resisted successfully all the strength and stratagems of the Persians, for the space of 18 months; and fell at length into the hands of Darius by the following extraordinary instance of fortitude in one of his officers. Zopyrus, one of the principal noblemen in the Persian court, appeared in the presence of his prince, covered with blood, deprived of his nose and ears, torn with stripes, and wounded in various parts of his body; unfolded to the astonished monarch his design of deserting to the enemy, and arranged his future plan of operations. Approaching the walls of the city, he was carried before the governor, detailed the cruel treatment which he professed to have received from Darius; offered his services to the Babylonians, who were well acquainted with his rank and abilities; acquired their confidence by several successful sallies; obtained at length the chief command of their forces, and thus easily found means to betray the city to his master. As soon as Darius was in possession of Babylon, he ordered its hundred gates and its impregnable walls to be demolished; put to death 3000 of those who had been principally concerned in the revolt; and sent 50,000 women from different parts of his empire, to supply the place of those who had been so cruelly destroyed at the commencement of the siege. In the year B. C. 478, Xerxes, the successor of Darius, returning from his inglorious invasion of Greece, passed through the city

of Babylon; and, partly from hatred of the Sabian worship, partly with a view to recruit his treasures, plundered the temple of Belus of its immense wealth, and then laid its lofty tower in ruins. In this state it continued till the year B. C. 324, when Alexander the Great made an attempt to rebuild this sacred edifice, and to restore its former magnificence. But, though he employed about 10,000 men in this work for the space of two months, his sudden death put an end to the undertaking before the ground was cleared of its rubbish. This mighty city declined very rapidly under the successors of Alexander; and, in the year 294, A. C. was almost exhausted of its inhabitants by Seleucus Nicator, who built in its neighbourhood the city of Seleucia, or New Babylon. It suffered greatly from the neglect and violence of the Parthian princes before the Christian æra; and every succeeding writer bears testimony to its increasing desolation. Diodorus Siculus, B. C. 44.; Strabo, B. C. 30.; Pliny, A. D. 66.; Pausanias, A. D. 150.; Maximus Tyrius, and Constantine the Great, as recorded by Eusebius,—all concur in describing its ruined condition; and Jerome at length informs us, that, about the end of the 4th century its walls were employed by the Persian princes as an inclosure for wild beasts, preserved there for the pleasures of the chase. It was visited about the end of the 12th century by Benjamin of Tudela in Navarre, who observed only a few ruins of Nebuchadnezzar's palace remaining, but so full of serpents and other venomous reptiles, that it was dangerous to inspect them nearly. A similar account is given by other travellers; by Texeira, a Portuguese; by Rauwolf, a German traveller in 1574; by Petrus Vallensis in 1616; by Tavernier, and by Hanway; but so very slight are the vestiges now to be found of ancient Babylon, that it is difficult to ascertain exactly the spot on which it once stood, so completely has been fulfilled the prediction of Isaiah: "Babylon, the glory of kingdoms, the beauty of the Chaldees excellency, shall be as when God overthrew Sodom and Gomorrah. It shall never be inhabited, neither shall it be dwelt in from generation to generation; neither shall the Arabian pitch tent there; neither shall the shepherds make their fold there. But wild beasts of the desert shall lie there, and their houses shall be full of doleful creatures; and owls shall dwell there, and satyrs shall dance there; and the wild beasts of the islands shall cry in their desolate houses, and dragons in their pleasant palaces." The striking accomplishment of scripture prophecies, in the conquest, decline, and desolation of Babylon, is very fully illustrated in Rollin's *Ancient History*, vol. ii. p. 140—154.; Newton's *Dissertations*, vol. vii. p. 285.; and Prideaux's *Connect.* vol. i. *passim*. See on the general subject of this article, *Ancient. Un. Hist.* vol. iv. p. 403, &c.; vol. i. p. 332, notes. Rollin's *Anc. Hist.* vol. ii. p. 16.; iii. p. 45. Prideaux's *Connect.* vol. i. p. 95, 120, 187, 242, 567. Gillies' *Hist. of World*, vol. i. p. 48. &c. (g)

BABYLON, EMPIRE OF, may be considered as the first great monarchy of which any records are to be found in history. It appears to have been founded a short time after the flood; and (according to the astronomical tables sent by Alexander to Aristotle) about 2234 years before Christ. Of this first Babylonian kingdom there is very little to be known, except what is related in sacred scripture; that, about 2000 years B. C., it consisted, under Nimrod, of four cities, Babel, Erech, Accad, and Calneh; that, about 100 years afterwards, it

was enlarged by Ashur, who built several other cities, and particularly the first Nineveh, on the eastern bank of the Tigris, 300 miles above Babylon; and that it continued till the year B. C. 1230, when Ninus, having overrun the greater part of Asia, founded a second Nineveh, between the rivers Tigris and Euphrates, about 50 miles from Babylon, and thus established what is called the Assyrian monarchy. But what is generally understood by the Babylonian empire, began about 606 years before Christ, when Belesis, or Nebopolassar, hereditary satrap of Babylon, revolted against the Assyrian monarch Sardanapalus; and having destroyed that prince and his capital Nineveh, transferred the seat of power to his own city. Thus there may be said to have been two distinct kingdoms in Babylon; one preceding, and the other following, the Assyrian empire. Or, rather, more properly speaking, there were three great æras of the same monarchy in the country of Assyria. The first of these commences with Nimrod, in the year B. C. 2000, when Babylon was the seat of power; the second with Ninus, in the year 1230, when Nineveh became the metropolis of the empire; and the third with Belesis, in the year 606, when Babylon once more beheld the sovereigns of the East residing in her palaces. This subject indeed is beset with inextricable difficulties, and involved in impenetrable darkness; but the above statement, which is founded upon the observations of the learned and ingenious Dr Gillies, in his *History of the World*, (vol. i. p. 50, 130,) seems much more simple in itself, as well as more consistent with history, than either the common account, which makes the Assyrian monarchy almost coeval, but altogether unconnected with the first kingdom in Babylon; or that of Sir Isaac Newton, who dates its origin so late as the year B. C. 770.

Leaving our readers to decide this point for themselves, we proceed to the proper subject of this article, namely, to give a short sketch of the second Babylonian empire, established by Belesis, or Nebopolassar, upon the ruins of the Assyrian monarchy, about 606 years B. C.

NEBOPOLASSAR, OR, as he is also called, NEBUCHADNEZZAR, continued in close alliance with Cyaxares the Mede, by whose assistance he had acquired the sovereignty, and by whose friendship he became so powerful as to excite the apprehensions of the neighbouring princes. While he was employed in resisting the Scythians, who had made themselves masters of Upper Asia, Necho, king of Egypt, invaded his dominions in the south, reduced the city Carchemish, or Circesium, and encouraged the Syrians in that quarter to revolt. Nebopolassar being now well advanced in years, sent his son Nebuchadnezzar, whom he had associated with himself in the empire, to reduce those countries to their former subjection. The young prince defeated the army of Necho near the Euphrates, retook the city of Carchemish, and quelled the insurgents in Syria: entered Judea, and took possession of Jerusalem; restored Jehoiakim to his throne, but carried to Babylon great numbers of the principal Jews, with the treasures of the palace, and part of the sacred vessels in the temple. In the mean time Nebopolassar died, and was succeeded by his son, upon his return from his expedition.

NEBUCHADNEZZAR II. called also LABYNETUS, occupied himself, during the first years of his reign, in enlarging and embellishing his capital; and during this

period occurred those events which are related in the book of Daniel, chap. ii. His tranquillity was interrupted by the revolt of Jehoiakim in Judea, who was soon reduced by the Babylonian generals; but Jechonias his son, having also attempted to shake off the Assyrian yoke, Nebuchadnezzar went in person to the siege of Jerusalem; and having made himself master of the city, he carried to Babylon all its treasures and sacred utensils, leaving the government to Zedekiah the uncle of Jechonias. Recalled in a short time to Judea by the revolt of Zedekiah, he defeated the Egyptians, who had come to the assistance of the Jews, took Jerusalem by storm, after a twelvemonth's siege, gave it up to pillage and slaughter, put out the eyes of the king, and carried him away captive. Upon his return to Babylon he erected a golden statue in the plain of Dura, sixty cubits in height, and commanded all his subjects to worship it as a divinity. (Dan. chap. iii.) About three years after this event, he again led his forces against the western nations, made himself master of Tyre after a siege of 13 years, overran the whole country of Egypt, returned to adorn his capital with the booty which he had acquired; and, having suffered the punishment of his pride, as related in Daniel, chap. iv. he died in the 44th year of his reign.

EVIL-MERODACH, who succeeded his father Nebuchadnezzar, is described as a weak and licentious prince, and was murdered by his own relatives, after having reigned little more than two years.

NERIGLISSAR, the husband of Evil-Merodach's sister, and one of the chief conspirators, reigned in his stead. Immediately after his accession, he began to make preparations for resisting the growing power of the Medes and Persians. After spending three years in forming alliances, and collecting troops, he marched to meet his opponents Cyaxares and Cyrus; and, in a bloody engagement with the latter, was defeated and slain.

LABOROSARCHOD, his son, succeeded to the throne. By his cruelty and oppression, he provoked several of his governors to raise the standard of rebellion, and to call in the aid of Cyrus. Marching to suppress these commotions, he was met by the Persian prince, defeated with great loss, and pursued to the very walls of his metropolis. After Cyrus had retired with his army, the Babylonian monarch indulged his vicious propensities to such excess, that his own subjects, unable any longer to endure his tyrannical conduct, conspired against his life, and put him to death, in the ninth month of his reign. He was succeeded by

NABONADIUS, who is called also **LABYNETUS**, and who is the same with **BELSHAZZAR** mentioned in sacred scripture. He was the son of Evil-Merodach, by his queen Nitocris; and was the grandson of the great Nebuchadnezzar. His mother Nitocris, who was a woman of extraordinary talents, took upon herself the management of public affairs; and while her son was pursuing his pleasures, she made every exertion to preserve the tottering empire. She completed many of the works which Nebuchadnezzar had begun; and, when Cyrus renewed his attacks upon the frontier towns, she employed the utmost activity in constructing new fortifications for the defence of the capital. Belshazzar at length, in the fifth year of his reign, repaired in person to the court of Cræsus king of Lydia, carrying with him an immense treasure; and with the aid of that prince, as well as by the influence of his wealth, framed a very formidable confederacy against Cyrus. Hav-

ing hired a numerous army of Egyptians, Greeks, and other nations in Lesser Asia, he appointed Cræsus to the command, and directed him to make an incursion into Media. These auxiliaries having been completely routed, Cræsus taken and dethroned, and Cyrus again advancing to Babylon, Belshazzar attempted to make head against him in the field, but was soon put to flight, and closely blockaded in his capital. After a siege of two years, the city was taken, as has been related in the preceding article; Belshazzar was slain in the assault upon his palace: and with him terminated the empire of the Babylonians, about 538 years before Christ. See Rollin's *Anc. Hist.* vol. ii. p. 34, &c. Prideaux's *Connections*, vol. i. p. 51, &c. *Anc. Univer. Hist.* vol. iv, p. 394, &c. Gillies' *Hist. of the World*, vol. i. p. 139. &c. (g)

BABYLON, COUNTRY OF, is generally called **Babylonia**, from the name of its first city Babel; or **Chaldea**, from the name of its inhabitants, the Chaldeans or Chasdim. When Babylon, instead of Nineveh, was the seat of the supreme power, the words **Babylonia** and **Chaldea** were equivalent with **Assyria**, and comprehended two large tracts of territory on opposite sides of the Euphrates. These were called in scripture, **Aram** beyond the river, and **Aram** on this side of the river. To the former, by way of distinction, the Greeks gave the name of **Assyria**, and to the latter that of **Syria**. The portion named **Assyria**, comprehended a space of 700 miles in length, between the rivers Euphrates and Tigris, from the Armenian mountains, in which they rise, to the Persian gulph, into which they then flowed in separate channels. This was divided into three parts, 1st, **Mesopotamia**, an appellation, indeed, which, in its literal meaning, was applicable to the whole extent, but which was limited to the northern region, where the rivers diverge in general a hundred, and in some places two hundred miles asunder, until, in their course towards the sea, they approach within 20 miles of each other, in the vicinity of Bagdad; 2d, **Babylonia**, extending from this narrow isthmus about 300 miles towards the Persian gulph, and never exceeding fourscore miles in its breadth between the rivers; and, 3d, The eastern district, properly named **Atur**, but frequently called **Mesenè** and **Adiabènè**, lying beyond the Tigris, and reaching to the foot of the Carduchian hills. It is to the second of these that the present article refers, and it is called indiscriminately **Babylonia** or **Chaldea**; but, in general, the latter name is used by sacred writers, and the former by profane. Sometimes, indeed, these appellations are appropriated severally to a particular district; the former denoting the country more immediately in the neighbourhood of Babylon, and the latter that which stretches southward to the Persian gulf.

The climate of this country is temperate and salubrious, but at certain seasons the heat is so intense, that the inhabitants were accustomed to sleep with their bodies partly immersed in water; and the same practice, according to the testimony of modern travellers, is continued to this day. It seldom rains there above three or four times in the course of a year; and the lands were watered by means of canals, trenches, and various sorts of engines, provided in great abundance for the purpose. The soil, naturally rich, and thus carefully supplied with moisture in the driest seasons, surpassed even that of Egypt in fertility; and is said to have generally yielded from 100 to 300 fold. Its vegetable productions grow to so extraordinary a size, that

Herodotus declines giving a particular description of them, lest he should incur the charge of exaggeration; but he mentions, as one instance, that the leaves of the wheat and barley were four fingers in breadth. It afforded every where a viscous clay, easily formed by the furnace, or even by the sun, into the hardest bricks; and the naphtha or bitumen, which was extremely abundant, furnished the firmest of all cements.

The government of this country was of the most despotic description; and the sovereignty was considered as hereditary. Every thing depended upon the will of the prince; and, hence, the laws were undefined, and the punishments arbitrary in the highest degree, (Dan. i. 10; ii. 5; iii. 19.) Three separate tribunals, however, were appointed to administer justice; the first of which took cognisance of adultery, and similar offences; the second of thefts; and the third of all other crimes. The principal officers of state seem to have been the captain of the guard, in whom the executive power resided; the prince of the eunuchs, who took charge of the education and subsistence of the youth of the palace; the prime minister or vizer, who was as the head of the police, and acted as chief justice in the empire; and the master of the magi, whose business it was to interpret prognostications, and divine the events of futurity to the king. The immediate household of the prince appears to have been extremely numerous; and particular districts were appointed to supply the different articles of food, which were requisite for the maintenance of the many thousands who daily fed at his tables.

The religious system of the Babylonians bore a near resemblance to that of the Egyptians; and has been very ingeniously ascribed to the following source. The sudden inundations of the Euphrates and Tigris, like those of the Nile, occasioning, alternately, the most rapid beneficial, or destructive changes in the face of nature, attracted the attention, and alarmed the anxiety, of the unenlightened people, who witnessed and experienced their momentous effects. These important changes were observed to have an evident connection with the vicissitudes of the seasons, and the revolutions of the heavenly bodies; and hence, these luminaries, whose influence was understood to be so powerful and extensive, were considered, at first, as the ministers or vicegerents of the Supreme Being, were gradually worshipped as mediators or intercessors for man, and were at length exalted to the rank of separate, but subordinate divinities. The sacerdotal families, devoted to the service of these deities, and thus led by their office to be continually observing the motions of the celestial bodies, gradually acquired such a degree of astronomical skill, as had the appearance of supernatural communications; and gave them a complete ascendancy over the minds of the multitude. This power they employed, as their fancy or interest suggested, in prescribing an immense variety of idolatrous rites and modes of worship; the most remarkable of which was the adoration of fire, and the offering of human victims in sacrifice. (See *SABIAN Worship*.) These sacerdotal tribes, who have been called by way of distinction, Chaldeans or Chaldees, were the philosophers as well as the priests of their country. They pretended to have derived their learning from the first instructor Oannes, who sprung from the primogenial egg; who was half man or god, and half fish; who appeared in the Red Sea, and taught the knowledge of letters and civiliza-

tion in general. This learning, as far as it went, they studied very minutely; and handed it down by tradition from father to son, with any little addition or improvement. It consisted chiefly of some absurd opinions about the formation and shape of the earth, a few astronomical observations, and a confused mass of astrological rules and prognostications of the weather. See *CHALDEAN Philosophy*.

As the priests and philosophers have been particularly distinguished by the appellation Chaldeans, the artists and mechanics have been denominated Babylonians. These appear to have made considerable attainments in geometry, architecture, metallurgy, and the general principles of mechanism; but almost nothing is known of their poetry, painting, statuary, and music. They excelled in the manufacture of rich veils, embroideries, carpets, cloth of gold, and every species of dress or furniture, in linen, cotton, and woollen stuffs. Their country afforded the best materials for dyeing; and their purple, like that of the Tyrians, formed a principal article of traffic. So very precious and splendid, indeed, were the vestments which they prepared, that Cato is said to have sold a Babylonian mantle, which had been left him as a legacy, but which he thought too rich for any one to wear; and that at Rome a set of Babylonian hangings for one apartment, was sold for a sum equivalent to 6500*l.* sterling.

If we consider the immense consumption made by the Babylonians of innumerable commodities, which were produced only in countries very remote from their own, it may be fairly concluded, that their opulence must have been very considerable, and their commerce very extensive. Prodigious masses of gold were employed in the statues and other ornaments which their temples contained. Twenty-five tons of frankincense were annually consumed on the altar of Jupiter alone. The people in general delighted in the liberal use of perfumes; and every Babylonian is said to have worn an engraved onyx, sapphire, or emerald, as his signet. Such an abundance of these commodities could have been procured only by the exchange of valuable merchandize, and by a regular communication with distant countries. They were supplied with those articles from northern India; and from the same country they brought, in great numbers, a particular species of hound, a mongrel brood of the dog and tyger, of remarkable size and strength, which was highly esteemed by the Babylonian princes and nobles in their favourite amusement the chase. These animals were so essential to royal magnificence, that whole districts were exempted from every other tribute, except the burden of defraying their maintenance; and even, in later times, they seem to have been equally indispensable to the sovereigns of the East, when the Sultan Bajazet had among the servants of his household 12,000 keepers of dogs. The Babylonian caravans carried on a very extensive traffic also with the countries in the West, penetrating through the Syrian desert to the Phenician traders on the Mediterranean; and proceeding by what was called the royal road, through the north of Asia Minor to the eastern borders of Europe. Their maritime commerce, likewise, was very considerable; and they are characterised by the Hebrew prophet, as a people, "whose cry is in the ships." They had much inland navigation by means of their numerous canals and rivers. The Tigris, on account of its rapidity, was navigable only about 100 miles north of Babylon; but they often sailed 300 miles

up the Euphrates to the city of Thapsacus, from which they distributed their spices and perfumes, by land carriage, to the neighbouring districts. In this inland communication, by means of water, the Armenian traders used small vessels of a very peculiar construction. They were little better than large baskets of willow branches covered with hides, of a round form, and guided by two oars or paddles. They were chiefly loaded with palm wine; and some of them were about 12 tons burden. They had frequently asses on board; and, having disposed of their cargo at Babylon, they sold the wooden frame of their boats, loaded these animals with the skins, and returned by land to Armenia. Their largest ships were employed, and their greatest commerce carried on, by their maritime colony at Gerra, which was situated about 200 miles from the mouth of the Euphrates; and whose merchants were the most wealthy and enterprising of all. They maintained an intercourse with the Phœnician factories on the Persian gulf, and with the Ethiopian mines in the neighbourhood of the Red Sea. Thus they had access to the treasures of Sofala or Ophir; and supplied the city of Babylon with the principal part of its spices, perfumes, gems, ebony, ivory, and gold.

One of the most remarkable customs of the Babylonians was the manner in which they disposed of their young women in marriage. They were all brought into the public market-place, where the most beautiful were sold to the highest bidder; and, from the money thus procured, portions were assigned to be given along with those who were deficient in personal attractions. One of their most abominable regulations was that which required every female to suffer prostitution once in her life in the temple of Venus. And one of their most useful practices was that by which they endeavoured to supply the want of professional physicians. The sick were brought out to the public places of resort; and all passengers, of whatever rank, as well as all strangers, of whatever country, were considered as bound in humanity to inquire into the nature of their diseases, and to suggest such remedies as they might have known to be useful in similar cases. The Babylonians were very temperate in their diet, and, like the Hindoos, lived chiefly upon grain; but in their dress and household accommodations, they were very effeminate and extravagant. Their inner garment was of fine linen, descending to their feet; above this, they wore a woollen tunic; and over the whole was thrown a short white cloak to repel the rays of the sun. Their heads were covered by linen mitres or turbans, plaited with much art; their feet were protected by light slippers; their bodies sprinkled with perfumes; and in their hand they generally carried a staff or cane, shaped at the top into the form of an apple, flower, bird, or some other characteristic emblem. Their habitations were adorned in a manner equally superb; their floors glowed with carpets of the most brilliant colours; and their walls were hung with the most beautiful tissues, named Sindones. They are represented, however, as very degraded in their intellectual and moral character; as credulous and superstitious; debauched and voluptuous in the highest degree; and, to the general prevalence of these luxurious and licentious habits, is unquestionably to be attributed the easy overthrow of such a powerful monarchy, and the immediate subjugation of such a populous empire. See *Anc. Univ. Hist.* vol. iv. p. 332, &c. *Gillies' Hist. of World*, vol. i. p. 60, 72, 168, 195. (7)

BABYROUSSA, or BABIROUSSA. See *Sus* MAMMALIA.

BACCHANALIA, ORGIA, or DIONYSIA, the sacred rites of Bacchus were celebrated every third year, hence called *Trieterica*, in the night, chiefly on Cithæron, and Ismeus, in Bœotia; and on Isgnarus, Rhodope, and Edon, in Thrace.

In these rites, it was common for the votaries to put on fawn skins, fine linen, and mitres; to carry *thyrsi*, drums, pipes, and rattles; and to crown themselves with garlands of vine, ivy, &c. Some imitated Pan, Silenus, and the Satyrs; and this motley and frantic multitude ran about the hills and deserts, tossing their heads, and filling the air with hideous yells, exclaiming continually, "Evoc, Sabae, Attes Hues," &c. The rites of Bacchus were celebrated at Athens in the following manner: The Bacchanals were followed by certain persons carrying vessels, the first of which was filled with water; after these came a select number of honourable virgins, carrying little baskets of gold, filled with all sorts of fruit. In these consisted the most mysterious part of the solemnity; and to make the ceremony more horrible, serpents were introduced among the fruit, which were continually crawling out and terrifying the spectators. Next came the Phallophori, carrying the Phallus, which was a representation of the male genitals, and singing obscene songs. There were also persons employed to carry the Fan, which was essential in these ceremonies, called by Virgil *Mystica vannus Iacchi*.

These festivals were distinguished by every kind of extravagance, lewdness, and enormity. Julius Firmicus informs us, that one part of the ceremony consisted in tearing, with their teeth, and devouring the flesh of a bull, whilst the animal was yet alive: *Vivum laniant dentibus taurum*. This was called *omophagia*. But this was not the worst; for we learn from Porphyry, that, in the islands of Chios and Tenedos, the votaries of Bacchus sacrificed to him, *αδελφωπον διασπαιντες*, by tearing a man limb from limb. From this we may observe, that the story of Pentheus being torn to pieces by the Bacchanals, if not a reality, is at least a fable founded on facts.

It is impossible to ascertain the origin or meaning of these horrid and unnatural rites. Perhaps, like the worship of Bacchus, they may be traced to India, (See *Bacenus*;) but this would throw but little light upon the subject. Mr Faber has proposed an explanation, which, we fear, will scarcely prove satisfactory to our readers. He supposes, that the Bacchanalia were intended, originally, as a scenical representation of the fall of our first parents. "As the woman first plucked the apples, and afterwards carried them to her husband, when this subject came to be mythologically represented, the fruit, which constituted the most mysterious part of the Dionysia, was naturally placed in the hands of females, and by them alone borne in the sacred procession. For similar reasons, the serpent, which took his station near the forbidden tree, and there tempted the woman to transgress the prohibition of God, was, in the mystic rites of Dionysus, closely connected with the fruit, and carried along with it in the same golden baskets. And in the term *Evoc*, which resounded from every mouth during the continuance of the festival, we may trace a manifest allusion to the name of our unhappy parent, through whose frailty sin and death entered into the world, and disturbed the original harmony

of universal nature." Whatever our readers may think of this explanation, it is by no means new. It is adopted both by Epiphanius (tom. ii. l. 3.) and by Clemens Alexandrinus (*Cohortatio*, p. 11.) They seem to rest their opinion chiefly on the exclamation *Evoe*, which, Clemens says, means *Εὐοὐ ἐκείνου, δι ἧ η πλανη παρκο-λασθησε*, *that Evoe by whom sin was introduced.*

To us it appears, that the exclamation, *Evoe*, *Sabae*, *Attes Hues*, which was utterly unintelligible to the Greeks, is evidently corrupted Hebrew, and that it was originally a title of the true God. It may very easily be restored to *Jeve Sabaoth Atta Hue*, i. e. *O Lord of Hosts, thou art God.* See Parkhurst's *Lex.* on the words *יהוה* and *עבד*. For the Bacchanian rites, see Potter's *Antiq. of Greece*, vol. i. Bryant's *Mythology*, vol. ii. Faber's *Horæ Mosaicæ*, vol. i. (g)

BACCHARIS, a genus of plants of the class Syngenesia, and order Polygamia Superflua. See BOTANY. (w)

BACCHUS, the god of wine, the son of Jupiter and Semele. He is represented as always young, crowned with ivy or vine leaves, and sometimes with horns, hence called *Corniger*, holding in his hand a thyrsus, or spear bound with ivy: his chariot was drawn by tygers, lions, or lynxes, attended by Silenus, his preceptor, bacchanals, and satyrs. Bacchus is equally celebrated in Greece, Egypt, and India; and each of these countries claims the honour of having given him birth. He was a very important personage in ancient mythology, and is represented as the great promoter of civilization over the world. He is said to have settled men in society, and to have taught them agriculture, commerce, and navigation; hence he is reckoned the same as the Egyptian Osiris. The muses have also been indirectly indebted to him; for it is said, that the first attempts at tragedy were made at the annual festivals in honour of Bacchus, (*Hor. De Arte Poet.* 220.) And many seem to have thought, that his influence was not less necessary than that of Apollo, to give birth to poetic inspiration:

*Emius ipse pater nunquam nisi potus ad arma
Prosiluit dicenda.*

Numberless conjectures have been offered to explain the fabulous history of Bacchus. Some suppose him to have been Moses; Bochart imagines that he was Nimrod, and that his name is properly Bar Chus, *the son of Chus*; Mr Bryant contends that he was Noah; and Sir William Jones, with still greater probability, as we shall afterwards see, supposes him to have been Ramah, the son of Chus, or Cush; and suggests, that his name may be derived from *Bagis*, one of the names of Siva.

One of the most celebrated of the exploits of Bacchus was his conquest of India: this circumstance would naturally lead us to look to that quarter of the world for some illustration of his history. Accordingly we learn from Arrian, (*Hist. Ind.* p. 318, 321.) that the worship of Bacchus, or Dionysus, was common in India, and that his votaries observed a number of rites similar to those of Greece: such as crowning themselves with ivy; wearing the *nebris*, or spotted skins, like the Bacchanians in the west; and using cymbals and tabours in their religious ceremonies. On this account, when Alexander entered India, the natives considered the Greeks as belonging to the same family with themselves; and, when the people of Nysa sent the principal person of their city to solicit their freedom of the Grecian con-

queror, they conjured him by the well known name of Dionysus, as the most effectual means of obtaining their purpose. "O king, the Nyssæans entreat thee to allow them to enjoy their liberties and their laws, out of respect to Dionysus." Arrian. *Exp. Alex.* l. v. p. 196.

But Sir William Jones, in his dissertation on the gods of Greece, Italy, and India, has shewn, beyond the possibility of a doubt, that the worship of Bacchus was not only common in India, in the time of Alexander, but actually is so at the present day; and has demonstrated, that the Greeks must either have derived it from that country, or at least from some common source. As his observations on this subject are both curious and interesting, we shall give them in his own words:

"Two" incarnate deities of the first rank, Rama and Crishna, must now be introduced. The first of them, I believe, was the Dionysus, or Bacchus, of the Greeks, whom they named *Bromius*, without knowing why; and *Bugenes*, when they represented him *horned*; as well as *Lycios*, and *Eleutherios*, the Deliverer; and *Triambos*, or *Dithyrambos*, the Triumphant. Most of these titles were adopted by the Romans, by whom he was called *Bruma*, *Tauriformis*, *Liber*, *Triumphus*: and both nations had records, or traditional accounts, of his giving laws to men, and deciding their contests; and of his improving navigation and commerce; and what may appear yet more observable, of his conquering India, and other countries, with an army of *satyrs*, commanded by no less a personage than Pan. It were superfluous, in a mere essay, to run any length in the parallel between this European god and the sovereign of *Jyodhya*, whom the Hindoos believe to have been an appearance on earth of the *Preserving Power*; to have been a conqueror of the highest renown, and to have commanded in chief a numerous and intrepid race of those large *monkeys* which our naturalists have denominated Indian satyrs. His general, the prince of satyrs, was named Hanumat: and with workmen of such agility, he soon raised a bridge of rocks over the sea, part of which, say the Hindoos, yet remains; and it is probably the series of rocks to which the Mussulmans and Portuguese have given the foolish name of Adam's (it should be called Rama's) Bridge. Might not this army of satyrs have been only a race of mountaineers, whom Rama, if such a monarch ever existed, had civilized? However that may be, the large breed of Indian apes is at this moment held in high veneration by the Hindoos, and fed with devotion by the Bramins, who seem, in two or three places on the banks of the Ganges, to have a regular endowment for the support of them: they live in tribes of 300 or 400; they are wonderfully gentle, (I speak as an eye witness,) and appear to have some kind of order and subordination in their little sylvan polity. We must not omit, that the father of Hanumat was the god of wind, named *Pavan*, one of the eight genii; and as Pan improved the pipe, by adding six reeds, so one of the four systems of Indian music bears the name of Hanumat, as its inventor, and is now in general estimation."

Sir William afterwards observes, "the first poet of the Hindoos was the great Valmic; and his Ramayan is an epic poem on the subject of Rama, which in unity of action, magnificence of imagery, and elegance of style, far surpasses the learned and elaborate work of Nonnus, entitled *Dionysiaca*: and I am confident, that an accurate comparison of the two poems would prove Dionysus and Rama to have been the same person: and I incline to think that he was Rama, the son of Cush, who might

have established the first regular government in this part of Asia. I had almost forgotten, that *Meros* is said by the Greeks to have been a mountain of India, on which their Dionysus was born, and that *Meru*, is also a mountain near the city of Naishada, or Nysa, called by the Grecian geographers Dionysopolis, and universally celebrated in the Sanscrit poems."

These extracts throw great light on Grecian mythology. They prove clearly that the Greeks derived the history of their Dionysus from India: they seem to account for the veneration paid to fauns and satyrs; and the mountain Meru, near Nysa, seems to have given rise to the ridiculous story of Bacchus being sewed into the thigh, (*ungos, meros*) of Jupiter. The difficulty however is only removed one step farther back; for the Indian fables respecting Rama are still involved in impenetrable darkness. Perhaps, however, some farther light may yet be thrown on this subject from the stores of oriental literature. See Bryant's *Mythology*, vol. iv. 250, 273; v. 94; vi. 141. *Asiatic researches*, vol. i. (g)

BACHELOR, or BATCHELOR (in the Latin of the middle age, *Baccalaureus*.) a term which, in its various applications, seems to have been appropriated to those who were in the first stage of advancement towards some particular honour.

In the ages of chivalry and of feudal government, those knights were styled *bachelors*, whose possessions were too small to entitle them to have their own banner displayed in battle; or who, being yet under age, were obliged to march under another's standard, though rich and powerful enough themselves to rank in the order of bannerets. Camden describes bachelors as persons superior to esquires or gentlemen, but inferior in age and standing to knights. Others maintain, that this was the common appellation of persons in all degrees between gentlemen and barons; an opinion which seems to be supported by a clause in an ancient statute-book, in which it is enacted, that "when the admiral rideth to assemble a shippe of war, or other, for the business and affairs of the realm, if he be a *bachelor* he shall take for his day-wages four shillings sterling; if he be an earl or baron, he shall take wages after his estate and degree."

The title of *bachelor* was likewise given to the young cavalier, who had received the military girdle in consequence of finishing his first campaign; and to him who, in his first tournament, was so fortunate as to triumph over his antagonist. (π)

BACHELORS, KNIGHTS, in Heraldry. See KNIGHTS *Bachelors*.

BACHELOR, in colleges, is the title by which those are distinguished who have obtained the *bacca laureate*, the first literary degree. Before the degree of bachelor of arts can be obtained at Oxford, it is necessary to have studied there four years; three years more to become master of arts; and seven more to commence bachelor of divinity. At Cambridge, the student must have been admitted near four years before he can take the degree of bachelor of arts; three years more before he can be made master; and seven more to become bachelor of divinity. The degree of bachelor of law may be obtained after the candidate has spent six years in that study.

At Paris, before a person is enabled to pass bachelor in theology, he must have attended for two years to the study of philosophy, and for three years to that of theology, and have held two acts of examination in the Sorbonne. In the canon law none can be admitted bachelor till he has employed two years in the study of that sci-

ence, and sustained an examination according to the prescribed forms; and to become bachelor of physic, it is necessary to have been four years master of arts, and afterwards to have studied medicine for two years: the student is then invested with the fur, as a preliminary step to his license. Previous to the foundation of divinity professorships in the university of Paris, those who had studied divinity six years were admitted to enter upon their course, and were called *baccalarii cursores*. There were two courses, in the first of which they were engaged during three successive years, in explaining the Bible, whence they were denominated *baccalarii biblici*; in the second, they were employed for one year in explaining the matter of the sentences; they were then called *baccalarii sententiarii*: when they had completed both courses, they were styled *baccalarii formati*, *formed bachelors*. The title of *formed bachelor* is now given to one who has regularly obtained his degree, after going through the course of study and exercises required by the statutes; in contradistinction to the *current bachelor* who is admitted through special favor.

The etymology of the word *bachelor* has been much controverted. It is even extremely uncertain whether it was first employed as a term of military or literary honour. Among those who suppose it to have been originally a military term, we may mention Cujas, Ducange, Caseneuve, and Altaferra. Cujas derives the word from *bucellarius*, a kind of cavalry once held in great esteem: Ducange maintains that it comes from *baccalaria*, a kind of fees or farms, consisting of several pieces of ground of about twelve acres each, or as much as two oxen could plough; the possessors of which *baccalaria* were called bachelors: Caseneuve and Altaferra deduce it from *baculus* or *bacillus*, a staff, because the young cavaliers exercised themselves in fighting with staves. Martinus, however, with perhaps more probability, maintains that this word was, in its primitive application, restricted to those poets who, according to the custom of Italy, were crowned with laurels, and were thence called *baccalaurei*, or *bachelors*. (μ)

BACHELORS, in the livery companies of London, are those who, though members of the company, are not yet admitted to the livery. These companies generally consist of a master, two wardens, the livery, and the bachelors, who are yet only expectants of preferment in their company. (μ)

BACHELORS, in the six companies of merchants in Paris, are those elders, who, having served the offices, are entitled to assist the masters and wardens in some of their duties, particularly in judging of the *chef d'œuvres* of those who stand candidates for the honour of masters.

BACHELOR, in its most general acceptation, is applied to a man, who remains in a state of celibacy.

Almost all nations have regarded bachelors as a set of delinquents, who withhold from the state an important part of its due advantages, and who are therefore fairly liable to peculiar penalties. It is one of the 613 precepts of the Rabbins, that all persons (with very few exceptions) are bound to marry at the age of twenty; and it is a maxim frequent among these casuists, that he who does not endeavour to leave children behind him ought to be accounted a homicide.

Among the Lacedemonians, bachelors were branded with infamy, excluded from all civil and military offices, and even debarred from the public spectacles and amusements. They were obliged to appear at certain festivals, to be led naked round the market-place, and thus expo-

sed to the public derision. These insults were sometimes accompanied with blows and scourging; and, to complete the affront, they were forced to sing certain songs composed for their own disgrace. Among the Romans, too, celibacy, though frequent, was always greatly discouraged. Fines were often imposed by the censors on old bachelors; and Dionysius of Halicarnassus mentions an old statute, by which all persons were commanded to marry as soon as they reached the age of maturity. A direct law against celibacy was proposed, at the desire of Augustus, by the consuls Papius and Poppæus, from whom it received the name of *Lex Papia Poppæa*. This law, the immediate design of which was to repair the desolation occasioned by the civil wars, met with great opposition from the nobility. It provided, that whoever in the city should have three children, in other parts of Italy four, and in the provinces five, should be entitled to certain privileges and immunities; and that they who lived in celibacy should be incapable of succeeding to an inheritance, except of their nearest relations, unless they married within 100 days after the deed of the testator.

In this country taxes have occasionally been levied on bachelors; and at present, by statute 25 Geo. III. cap 43, the taxes imposed on the public in general are, in some cases, increased with regard to bachelors, particularly the duty on servants. (κ)

BACK-GAMMON, the name of a popular and interesting game, played by two persons, with a box and dice, upon a table divided into two parts, upon which there are 12 black and 12 white points. Each adversary has 15 men, black and white, to distinguish them, which are arranged thus: Supposing you play into the right-hand table, two upon the ace-point in your adversary's table, five upon the six-point in the opposite table, three upon the cinque point in the hithermost table, and five on the six point in your own table: the grand object is to bring the men round into your own table; all throws that contribute towards it, and prevent your adversary doing the same, are advantageous, and *vice versa*. The first best throw upon the dice is esteemed aces, as it stops the six-point in the outer table, and secures the cinque in your own, in consequence of which your adversary's two men upon your ace-point cannot get out with either quatre, cinque, or six. The first throw, therefore, is an advantage frequently asked and given between players that are not equally skilful.

In the following article we shall present our readers with an abstract of Hoyle's *Treatise on Back-gammon*.

It is necessary for a learner to know how many points he has the chance of throwing upon the two dice, one throw with another.

There are 36 chances upon two dice.

Throws.	Chances.	Throws.	Chances.
2 Aces	4	5 and 4 twice . . .	18
2 Deuces	8	5 and 3 do.	16
2 Trois	12	5 and 2 do.	14
2 Fours	16	5 and 1 do.	12
2 Fives	20	4 and 3 do.	14
2 Sixes	24	4 and 2 do.	12
6 and 5 twice	22	4 and 1 do.	10
6 and 4 do.	20	3 and 2 do.	10
6 and 3 do.	18	3 and 1 do.	8
6 and 2 do.	16	2 and 1 do.	6
6 and 1 do.	14		—

Points.
Divided by 36)294(8
288
6

294 divided by 36, shews, that one throw with another you may expect 8 upon two dice.

The chances upon two dice are as follow:

Throws	Chances.	Throws.	Chances.
2 Sixes	1	5 and 4 twice	2
2 Fives	1	5 and 3 do.	2
2 Fours	1	5 and 2 do.	2
2 Trois	1	*5 and 1 do.	2
2 Deuces	1	4 and 3 do.	2
2 Aces	1	4 and 2 do.	2
6 and 5 twice	2	*4 and 1 do.	2
6 and 4 do.	2	3 and 2 do.	2
6 and 3 do.	2	*3 and 1 do.	2
6 and 2 do.	2	*2 and 1 do.	2
*6 and 1 do.	2		—
			36

To find out by this table what are the odds of being hit upon a certain, or flat die, (the ace for example,) look in the table, where it is thus * marked.

Throws.	Chances.	Throws.	Chances.
*2 Aces	1	*3 and 1 twice	2
*6 and 1 twice	2	*4 and 1 do.	2
*5 and 1 do.	2	*2 and 1 do.	2
			—
		Total,	11
		Which subtracted from .	36
			—
		The remainder is	25

Hence it appears, that it is 25 to 11 against hitting an ace, upon a certain, or flat die. The same method may be taken with any other flat die, as with the ace.

What are the odds of entering a man upon 1, 2, 3, 4, or 5 points?

	Answer.	Reduced.		
To enter it	upon 1 point is 11 to 25 upon 2 points is 20 to 16 upon 3 points is 27 to 9 upon 4 points is 32 to 4 upon 5 points is 35 to 1	or nearly	For. Against.	For. Against.
			4 to 9	5 to 4
			3 to 1	8 to 1
			5 to 7	35 to 1

What are the odds of hitting, with any chance, in the reach of a single die?

	Answer.	Reduced.		
To hit	upon 1 is 11 to 25 upon 2 is 12 to 24 upon 3 is 14 to 22 upon 4 is 15 to 21 upon 5 is 15 to 21 upon 6 is 17 to 19	or nearly	For. Against.	For. Against.
			4 to 9	1 to 2
			2 to 3	5 to 7
			5 to 7	8½ to 9½

What are the odds of hitting with double dice.

	Answer.	Reduced.		
To hit	upon 7 is 6 to 30 upon 8 is 6 to 30 upon 9 is 5 to 31 upon 10 is 3 to 33 upon 11 is 2 to 34 upon 12 (or 2 Sixes) 1 to 36	or nearly	For. Against.	For. Against.
			1 to 5	1 to 5
			1 to 6	1 to 11
			1 to 17	1 to 35

To explain farther how to use the table of 36 chances, to find the odds of being hit upon any certain or flat die. This second example shews how to discover by that the odds of being hit upon a 6.

2 Sixes 1	6 and 3 twice 2
2 Trois 1	6 and 2 twice 2
2 Deuces 1	6 and 1 twice 2
6 and 5 twice 2	5 and 1 twice 2
6 and 4 twice 2	4 and 2 twice 2
	—
	17

Which subtracted from . . . 36

The remainder is . . . 19

That is, 19 to 17 against being hit upon a 6.
 The odds of 2 love are about 5 to 2.
 and of . . . 2 to 1 . . . is 2 to 1.
 and of . . . 1 love . . . is 3 to 2.

1. If you play three up, your principal object in the first place is, either to secure your own or your adversary's cinque point; when that is effected you may play a bold game, and endeavour to gammon the adversary.

2. The next best point (after you have gained your cinque-point) is to make your bar-point, thereby preventing your adversary from running away with 2 sixes.

3. After you have proceeded thus far, prefer making the quatre-point in your own tables, rather than the quatre-point out of them.

4. Having gained these points, you have a good chance to gammon your adversary, if he is very much advanced: For, suppose his tables are broken at home, it will then be your interest to open your bar-point to oblige him to come out of your tables with a six; and having your men spread, you not only may catch that man which your adversary brings out of your tables, but will also have a probability of taking up the man left in your tables, (upon the supposition that he had two men there.) And if he should have a blot at home, it will then be your interest not to make up your tables; because, if he should enter upon a blot, which you are to make for the purpose, you will have a probability of getting a third man; which, if accomplished, will give you at least four to one of the gammon; whereas, if you have only two of his men up, the chance is that you do not gammon him.

5. If you play for a hit only, one or two of your adversary's men taken up makes it surer than a greater number, provided your tables are made up.

6. *Directions how to carry your men home.*—When you carry your men home, in order to lose no point, you are to carry the most distant man to your adversary's bar-point, that being the first stage you are to place it on; the next stage is 6 points farther, *viz.* in the place where your adversary's five men are first placed out of his tables; the next stage is upon the sixth point in your tables. This method is to be pursued till your men are brought home, except 2, when, by losing a point, you may often save your gammon, by putting it in the power of 2 fives or 2 fours to save it.

7. If you play to win a hit only, endeavour to gain either your own or your adversary's cinque-point; if that fails by you being hit, and he is forwarder than you, then you must throw more men into his tables, thus: Put a man upon your cinque or bar-point, and if your adversary neglects to hit it, you may then gain a forward, instead of a back-game; but if he hits you, you must play

for a back-game, and then the greater number of men which are taken up makes your game the better, because you by that means preserve your game at home; and you must then always endeavour to gain both your adversary's ace and trois-points, or his ace and deuce-points, and take care to keep three men upon his ace-point, that if you chance to hit him from thence, that may remain still secure to you.

8. At the beginning of a set do not play for a back-game, because you would thus play to a great disadvantage, running the risque of a gammon to win a single hit.

Directions for playing at the commencement of the game, the 36 chances of the dice, either for a gammon or a single hit.

1. Two aces, to be played on your cinque-point and bar-point, for either gammon or hit.

2. Two sixes, to be played on your adversary's bar-point, and on your own bar-point, for a gammon, or hit.

3. * Two trois, two to be played on your cinque-point, and the other two on your trois-point in your own tables, for a gammon only.

4. † Two deuces, two to be played on your quatre-point in your own tables, and two to be brought over from the five men placed in your adversary's tables, for a gammon only.

5. ‡ Two fours, to be brought over from the five men placed in your adversary's tables, and to be put upon the cinque-point in your own tables, for a gammon only.

6. Two fives, to be brought over from the five men placed in your adversary's tables, and to be put upon the trois-point in your own tables, for a gammon, or hit.

7. Six ace, you are to take your bar-point, for a gammon, or hit.

8. Six deuce, a man to be brought from the five placed in your adversary's tables, and to be placed on the cinque-point in your own, for a gammon, or hit.

9. Six and three, a man to be brought from your adversary's ace-point, as far as he will go, for a gammon, or hit.

10. Six and four, a man to be brought from your adversary's ace-point, as far as he will go, for a gammon, or hit.

11. Six and five, a man to be carried from your adversary's ace-point, as far as he can go, for a gammon, or hit.

12. Cinque and quatre, a man to be carried from your adversary's ace-point, as far as he can go, for a gammon, or hit.

13. Cinque-trois, make the trois-point in your tables, for a gammon, or hit.

14. Cinque-deuce, play two men from the five placed in your adversary's tables, for a gammon, or hit.

15. * Cinque-ace, bring one man from the five placed in your adversary's tables for the cinque, and play one down on the cinque-point in your own tables for the ace, for a gammon only.

16. Quatre-trois, bring two men from the five placed in your adversary's tables, for a gammon, or hit.

17. Quatre-deuce, make the quatre-point in your own tables, for a gammon, or hit.

18. † Quatre-ace, play a man from the five placed in your adversary's tables for the quatre, and for the ace play a man down upon the cinque-point in your own tables, for a gammon only.

19. Trois-deuce, bring two men from the five placed in your adversary's tables, for a gammon only.

20. Trois-ace, make the cinque-point in your own tables, for a gammon, or hit.

21. * Deuce-ace, play one man from the five placed in your adversary's tables for the deuce; and for the ace, play a man down upon the cinque-point in your own tables, for a gammon only.

Directions how to play the chances that are marked thus () for a hit only.*

1. * Two trois, play two of them on the cinque-point in your own, and with the other two take the quatre-point in your adversary's tables.

2. † Two deuces, play two of them on the quatre-point in your own, and with the other two take the trois-point in your adversary's tables.

By playing the two foregoing cases as directed, you avoid being shut up in your adversary's tables, and have the chance of throwing high doublets, to win the hit.

3. * Two fours, two of them are to take your adversary's cinque-point in his tables; and for the other two bring two men from the five placed in your adversary's tables.

4. * 1. Cinque-ace, play the cinque from the five men placed in your adversary's tables, and the ace from your adversary's ace-point.

5. * 2. Quatre-ace, play the quatre from the five men placed in your adversary's tables, and the ace from those on your adversary's ace-point.

6. * 3. Deuce-ace, play the deuce from the five men placed in your adversary's tables, and the ace from your adversary's ace-point.

N. B. The three last chances are to be played in this manner, because, by laying an ace down in your adversary's tables, you have a probability of throwing deuce-ace, trois-deuce, quatre-trois, or six-cinque, in two or three throws; in any of which cases you are to make a point, which gives you the better of the hit; and observe by the directions already given, that you are to play nine chances out of the thirty-six in a different manner, for a single hit, to what you would do when playing for a gammon.

General Observations.

1. By the directions given to play for a gammon, you are voluntarily to make some blots; the odds being in your favour that they are not hit; but should that so happen, in such case, you will have three men in your adversary's tables; you must then endeavour to secure your adversary's cinque, quatre, or trois point, to prevent a gammon, and must be very cautious how you suffer him to take up a fourth man.

2. Take care not to crowd your game, that is, putting many men either upon your trois or deuce-point in your own tables; which is, in effect, losing those men, by not having them in play. Besides, by crowding your game, you are often gammoned; as when your adversary finds your game open, by being crowded in your own tables, he may then play as he thinks fit.

3. By referring to the calculations, you may know the odds of entering a single man upon any certain number of points, and play your game accordingly.

4. If you are obliged to leave a blot, by having recourse to the calculations for hitting it, you will find the chances for and against you.

5. You will also find the odds for and against being hit by double dice, and consequently can choose a method of play most to your advantage.

6. If it is necessary to make a run, in order to win a hit, and you would know who is forwardest, begin with reckoning how many points you must have, to bring home to the six-point in your tables the man that is at the greatest distance, and do the like by every other man abroad; when the numbers are summed up, add for those already on your own tables (supposing the men that were abroad as on your six-point for bearing), namely, six for every man on the six, and so on respectively for each; five, four, three, two, or one, for every man, according to the points on which they are situated. Do the like to your adversary's game, and then you will know which of you is forwardest, and likeliest to win the hit.

Observations and Directions for a Learner to bear his Men.

1. If your adversary is greatly before you, never play a man from your quatre, trois, or deuce points, in order to bear that man from the point where you put it, because that nothing but high doublets can give you any chance for the hit: therefore, instead of playing an ace or a deuce from any of the aforesaid points, always play them from your highest point; by which means, throwing two fives, or two fours, will, upon having eased your six and cinque points, be of great advantage: whereas, had your six-point remained loaded, you must, perhaps, be obliged to play at length those fives and fours.

2. Whenever you have taken up two of your adversary's men, and happen to have two, three, or more points made in your own tables, never fail spreading your men, either to take a new point in your tables, or to hit the man your adversary may happen to enter. As soon as he enters one, compare his game with yours; and if you find your game equal, or better, take the man if you can, because it is 25 to 11 against his hitting you; which being so much in your favour, you ought always to run that risk, when you have already two of his men up: except you play for a single hit only, and playing that throw otherwise gives you a better chance for the hit, then do not take up that man.

3. Never be deterred from taking up any one man of your adversary by the apprehension of being hit with double dice, because the fairest probability is 5 to 1 against him.

4. If you should happen to have five points in your tables, and to have taken up one of your adversary's men, and are obliged to leave a blot out of your tables, rather leave it upon doublets than any other, because doublets are 35 to 1 against his hitting you, and any other chance is but 17 to 1 against him.

5. Two of your adversary's men in your tables are better for a hit than any greater number, provided your game is forwardest; because having three or more men in your tables gives him more chances to hit you, than if you had only two men.

6. If you are to leave a blot upon entering a man on your adversary's tables, and have your choice where, always chuse that point which is the most disadvantageous to him. To illustrate this, suppose it is his interest to hit or take you up so soon as you enter: in that case leave the blot upon his lowest point, that is to say, upon his deuce, rather than upon his trois, and so on, because

all the men your adversary plays upon his trois or his deuce-points are in a great measure out of play, those men not having it in their power to make his cinque-point, and consequently his game will be crowded there and open elsewhere, whereby you will be able also much to annoy him.

7. Prevent your adversary from bearing his men to the greatest advantage, when you are running to save a gammon: suppose you should have two men upon his ace-point, and several others abroad; though you should lose one point or two in putting the men into your tables, yet it is your interest to leave a man upon the adversary's ace-point; which will prevent him bearing his men to his greatest advantage, and will also give you the chance of his making a blot, that you may hit. But if, upon a calculation, you find you have a throw, or a probability of saving your gammon, never wait for a blot, because the odds are greatly against hitting it.

Laws of Back-gammon.

1. If you take a man or men from any point, that man or men must be played.

2. You are not understood to have played any man till placed upon a point, and quitted.

3. If you play with 14 men only, there is no penalty attending: because with a lesser number you play to a disadvantage, by not having the additional man to make up your tables.

4. If you bear any number of men before you have entered a man taken up, and which consequently you was obliged to enter, such men, so borne, must be entered again in your adversary's tables, as well as the man taken up.

5. If you have mistaken your throw, and played it, and if your adversary has thrown, it is not in your or his choice to alter it, unless both parties agree.

BACK STAFF, or **BACK QUADRANT**, the name of an instrument invented by Captain Davis, for taking the altitude of the sun at sea. It is called the English quadrant by the French. See **QUADRANT**. (*j*)

BACON, **ROGER**, known also by the appellation of the *Admirable Doctor*, was the greatest philosopher of the 13th century, and, in the estimation of some respectable writers, the brightest genius which modern Europe ever produced. He was born at Ilchester, in the year 1214, and, to the utmost verge of a long life, employed his versatile talents in cultivating the richest fields of science and literature. His early studies, at Oxford, were pursued with an eagerness and assiduity, which, at the same time, insured success, and earned the strongest marks of favour from his instructors. Transferring the scene of his education from England to France, in conformity with the usual practice of the times, he availed himself of the prelections delivered by the most distinguished professors in the university of Paris. His extraordinary attainments, however, are to be attributed less to any advantages derived from scholastic tuition, than to his own intense and indefatigable application. If we form an estimate of the merits of his contemporaries from the voluminous remains of the applauded triumvirate, Albertus, Aquinas, and Bonaventura, to whose irrefragable authorities almost every school paid implicit deference, and whose names eclipsed the glories of all their rival doctors, we shall easily perceive how little Bacon owed to his preceptors, and how much may be achieved by the well-directed la-

hours of a sound and vigorous mind. His intimate knowledge of Oriental and Grecian learning was unrivalled, in an age when minute attentions to words constituted the whole of what was called erudition, and when frivolous philological distinctions were mistaken for the profundities of abstract science. But to his higher praise be it recorded, that, though long assailed by the rancour of prejudice, and obstructed by the vengeance of bigotry, he was the first in modern times, who, spurning the trammels of veteran authorities, pointed out the true road to discovery, and demonstrated the utility of his method, by exemplifying it in a brilliant train of successful investigations. At Paris he was advanced to the degree of doctor in divinity; and when he was twenty-six years of age, he entered into the community of Friars-Minor, (or Grey Friars,) founded by St Francis; a monastic order which was then rising into great influence. About this time he returned to Oxford, where, having obtained a very extensive and valuable apparatus, he devoted himself chiefly to the study of mechanics, optics, astronomy, and chemistry. The mendicant brotherhood, to whose society he was unfortunately united, envious of his matchless honours, or fearful of his future ascendancy, conspired to blast the reputation, and to defeat the liberal ambition of one whose aims, uncontaminated by secular views, were exclusively directed to the advancement of the highest and most useful branches of human knowledge. He was slanderously reported to be addicted to necromancy and the unholy "communion of devils;"—and so powerful were the secret intrigues of his adversaries, that, though the heads of the university were friendly to his interest, it was deemed expedient, not only to prevent him from taking any share in the instruction of the youth, but even to condemn him to a rigorous confinement, aggravated by the harshest privations, and uncheered by the offices of friendship. It is said, that this hostility was inflamed by other passions not less cruel than jealousy. The monks and ecclesiastics were exasperated by the just animadversions, which Bacon had been heard to pass on the gross ignorance and errors of the religious orders, and by the indignant severity with which he had censured their prevalent vices. On the exaltation of Clement IV. to the papal dignity, he obtained a temporary respite from his persecutions; and this interval of unmolested quiet was dedicated with fresh ardour to the favourite occupations which had never ceased to engage his mind. Clement enjoyed his dignity only for three years; and his successor, Gregory X., was too much engrossed with the miseries of the Christians in Palestine, to bestow a single thought on the protection of a philosopher's retirement, or the redress of a philosopher's wrongs. It does not appear, however, that the personal liberty of Bacon was again abridged till the year 1278, when he was seized and imprisoned in France; and at the same time, an order was given by the guardian of the Franciscans, Jerome d'Ascoli, bishop of Palæstrina, afterwards Nicolas IV., interdicting the perusal of his writings. He lingered in this captivity for more than ten years; but at length he regained his freedom, and once more found his way to Oxford, where, at the venerable age of seventy-eight, death put a period to his labours and vexations, in the year 1292.

The published works of this great man are not numerous. The best known of these works is entitled *Opus Majus*, containing an abstract of his other treatises. An edition of this book was printed by Bowyer in 1733,

under the inspection of Dr Jebb. Another book, under the title of *Epistola Fratris Rogeri Baconis de secretis operibus artis et naturæ, et de nullitate magiæ*, has passed through several editions. A treatise addressed to Nicolas IV., *On the Means of avoiding the Infirmities of Age*, has been repeatedly printed; and several chemical essays written by him are inserted in the *Thesaurus Chemicus*, printed at Frankfort, in 1603 and 1620. Some of his manuscripts perished in the ruin of the Franciscan library at the Reformation; and a number of others have been discovered in the different libraries of Oxford; but little appears to be ascertained with regard to their value.

The present age is disposed to do ample justice to Friar Bacon, as the greatest ornament whose name was ever enlisted among the followers of St Francis; and the foul aspersions cast on him in his lifetime may be numbered among the most unequivocal testimonies to his worth. Admiring posterity sickens at being told, that the precious gem, which was capable of dazzling the whole intellectual world, was shut up from the view of a worthless generation, by the ignoble artifices of priestly zealots; but, with this bitter sensation, the most oppressed and friendless son of genius may delight to mingle the consolatory recollection, that from the joyless cell of Bacon issued the first vivid gleams of that unquenchable flame, which, after the lapse of ages, was destined to burst forth with augmented splendour, guiding the steps of the inquisitive in the paths of discovery, and lighting prostrate nations to the means of securing the inestimable liberties of conscience, and all the sacred immunities of free born men.

In exposing the futility and emptiness of monkish learning, Roger Bacon displayed the characteristic keenness of a great and original mind, confident of its own unquestionable right to speak with decision. We have already hinted at his vast acquirements in ancient learning. He contributed, more than any person of his age, to revive the neglected study of mathematics. His progress in mechanics and chemistry was so great, that he anticipated some of the proudest discoveries of subsequent times. The invention of gunpowder is now universally assigned to him, though it was claimed by a monk of the following century. He is the first writer who hints at any thing like the science of Aeronautics; and he speaks obscurely of many mechanical contrivances of vast power, the principles of which it is not easy to ascertain. His astronomical knowledge suggested to him that correction of the calendar, which was adopted in the 16th century by Gregory XIII. His proficiency in optics, considering the disadvantages under which he laboured, was truly wonderful. He was no stranger to the use of convex and concave lenses, the laws of refraction, the theory of mirrors, the power of burning glasses, and the grand invention of the telescope. He wrote also many treatises on grammar, geography, chronology, logic, metaphysics, ethics, theology, and medicine. That he was enticed into the wild speculations of alchemy, is the greatest cloud which hangs over his memory; and it is much to be regretted, that this epidemical infatuation of the times should have impeded his progress in the loftier and more profitable researches of truth. Fiction, however, has taken many unwarrantable liberties with his name; and some of the accounts which have been propagated, with regard to his attachment to occult and fanciful sciences, are sufficiently disproved by the authentic record of his writ-

ings. It would have been easy to amplify the list of his discoveries and sage conjectures; but it is enough to say, that whatever were the subjects which attracted his notice—and these included all the branches of human knowledge—he far outshone all the boasted luminaries of the age, all the *subtle, profound, and scrupulous* doctors, whose once-idolized names are now sinking in the oblivious gulf of time. See *Cave Hist. Lit. Wood Antiq. Oxon. Waddingi Annales Minor. Borrich D. Orig. Chem. Pits De illustr. Angl. Script. Bale, Script. Brit.*

BACON, SIR NICHOLAS, an English lawyer of great reputation, was born at Chislehurst, in Kent, in the year 1510. After studying at Cambridge, and travelling for some time in France, he entered into the society of Gray's Inn, and arrived at such eminence in the knowledge of law, that he was appointed king's attorney in the court of records. This office he held under Henry VIII. and Edward VI.; and when Elizabeth ascended the throne, he was made lord keeper of the great-seal, with a rank equal to that of chancellor. His royal mistress reposed unlimited confidence in his prudence and integrity, and the Protestants of that day revered him as one of the steadiest supporters of their interests. He conducted himself with equal firmness and moderation in his dignified office, and after having enjoyed it more than twenty years, died at the age of sixty-nine; leaving behind him the character of a faithful and discreet member of the council, an ingenious scholar, an eloquent, argumentative, and witty speaker, and a chief pillar of the state. He was the author of some political tracts,—of an exposition of the twelve minor prophets,—and of some commentaries on questions of law. See Mallet's *Bacon*, and sir R. Naunton's *Fragmenta Regalia*.

BACON, FRANCIS, lord Verulam, and Viscount St Albans, a philosopher, whose writings form a new epoch in the history of science, was born at York-house, London, on the 22d day of January 1560-1. He was the youngest son of sir Nicolas Bacon, by his second wife Anne, daughter of sir Antony Cook, tutor to Edward VI.

In his childish years, Francis Bacon displayed an uncommon precocity of talent; and the early presages of his superiority were amply verified by the fruits of his maturer studies. The gravity and propriety of his demeanour, when a boy, recommended him to the good graces of queen Elizabeth, who often admired the neatness and facility with which he replied to her questions. In his thirteenth year, he was committed to the care of Dr Whitgift, then master of Trinity College, Cambridge, afterwards Archbishop of Canterbury; and at the age of sixteen, according to his own account, he began to be dissatisfied with the philosophy of Aristotle, which had long formed the basis, or rather the whole substance of academical instruction. His father having destined him to the service of the state, found means to initiate him into the mysteries of the diplomatic life, by sending him to France, in his seventeenth year, with sir Amias Powlet, the ambassador. In this situation he enjoyed the entire confidence and approbation of his patron, by whom he was, in one instance, charged with a very important commission to the queen, in which he acquitted himself with great ability. About this time also he wrote an inquiry into the state of Europe, which afterwards gained him considerable applause in the political world. When he was nineteen years of age, r

gloom was thrown over his future prospects by the sudden death of his father, from whom he inherited a very small patrimony, as the youngest of five brothers.

Returning from France, he determined to study law; and, with this view, entered the honourable society of Gray's Inn, where he soon rose to great eminence, and, at the age of twenty-eight, was chosen their Lent reader. Two years afterwards he was made one of the clerks of the council. About this period his time was divided between the studies of law and philosophy; but his most ardent affections were set on the high offices of state; and to the attainment of these favourite objects he seized every opportunity of applying. He long and anxiously courted the good graces of lord Essex, and had also frequent access to the queen, who gave him great reason to believe that she was favourably disposed towards him. Her majesty, however, bestowed upon him no substantial mark of her regard, except the reversion of a lucrative office, that of register to the star-chamber, which became vacant about twenty years afterwards. It is alleged, that the antipathy or jealousy of Cecil, then secretary of state, obstructed his preferment, partly because the secretary disliked his attachment to the fortunes of Essex, and partly because he dreaded the ascendancy of his talents. Cecil is said to have been at great pains to impress on the queen's mind a conviction, that Bacon, being always immersed in abstract speculation, was ill qualified for the activity of public business; and it is to be regretted, that these insinuations, however questionable the motives which dictated them, did not operate as a permanent obstacle to his elevation. If he had been content with a private station, his philosophical inquiries might have been more successfully conducted; and those temptations might have been escaped, which afterwards had power to corrupt his integrity. The subsequent conduct of Bacon to his benefactor, the unfortunate earl of Essex, who had not only strained every nerve to ingratiate him with the queen, but augmented his fortune by some munificent donations, drew down on him the most unqualified expressions of public reprobation, and affixed a stain to his memory, which the lustre of his talents serves only to render more conspicuous. The obsequious candidate for courtly favour prostituted his abilities, by pleading against the man who had protected and enriched him, and violated the holy bonds of friendship, by extracting evidences of his patron's guilt from private letters which he spontaneously produced. As if all this had been too little, he was selected as the fittest instrument for attacking the posthumous fame of his sacrificed friend, and condescended to gratify the queen and the ministry, by publishing an elaborate *Declaration of the Treasons of Robert Earl of Essex*. His miserable *Apology* for his conduct, tended, in the opinion of the nation, rather to aggravate than to extenuate the baseness of deserting the man on whom he had long tanned; and thirsting for the infamy of one, whose blood might have satiated the hireling retainers of power. Elizabeth never requited Bacon for the execution of his odious task; and the ministry had no great encouragement to be lavish of their gifts to a man, who had proved himself capable of inflicting the deepest wounds on the object of his former adulation. Before this time, he had incurred the queen's displeasure, in consequence of the freedom with which he expressed his opinions in parliament, of which he became a member in 1592.

After the death of Elizabeth, the career of his ambition was more prosperous. Before James I. arrived in England, Bacon wrote letters to all the Scottish gentlemen of whom he had the slightest knowledge, offering his services to the king, and earnestly soliciting their interest to procure him employment in the affairs of state. He was one of the 237 persons, on whom the honour of knighthood was conferred, soon after the accession of the new sovereign; and he was also appointed one of the king's counsel learned. The endeavours of Cecil, earl of Salisbury, could not now defeat the servile arts by which Bacon rose progressively through so many steps of preferment. In 1605 he recommended himself to the notice of James, by addressing to him his great work, *Of the Advancement of Learning*, in the introduction to which he compliments that pedantic monarch, as being incomparably superior in judgment, learning, eloquence, and every princely attribute, to Julius Cæsar, Marcus Antoninus, Hermes Trismegistus, and all the potentates and demigods of ancient times. In 1607 he was appointed solicitor-general. Four years afterwards he was made joint judge of the knight-marshal's court. In 1613 he became attorney-general, and was sworn a member of the privy council. In 1617, he was raised to the high office of keeper of the great seal of England; and on the 4th of January 1619, he was advanced to the greatest legal dignity which the favour of his master could bestow,—the office of lord chancellor, an office which he had long laboured to procure, not only by descending to the most humiliating importunities, but also by vilifying the talents and principles of his rivals. In the course of the same year he was successively created baron Verulam, and viscount St Albans. James had advanced him not less than nine times: six in office, and three in dignity. After having thus rapidly attained the climax of his hopes, he sunk with still greater rapidity into the lowest degradation.

It is well known that the parliament which met in 1621 acted with a firm and determined boldness, of which there had previously been few examples in the history of England. In the examination of grievances, the commons were led to attend particularly to some patents for monopolies, which had excited loud murmurs among the subjects. Bacon and the other officers of state were supposed to have been the agents of Buckingham in obtaining these oppressive instruments. But charges of a more personal nature arose against the chancellor; and the House of Commons, after receiving the complaints of a great number of individuals, reported them to the lords, and accused his lordship of having, in his judicial capacity, received bribes from suitors before the court of chancery. At first he endeavoured to shelter himself from the effects of a minute investigation, by mingling vague protestations of his upright intentions with a reluctant confession, that, through the weakness of human nature, and the influence of evil example, he might have erred; at the same time labouring to persuade his judges, that the deprivation of his office would have a more salutary effect in preventing future delinquency, than the infliction of a severer punishment. His judges, not mollified by his submission, required him to give in a specific answer to all the charges. He sent a letter to the House, acknowledging himself guilty in almost all the twenty-eight articles, and attempting to palliate his criminality in a few of them. On the 5d of May, six weeks after

the investigation commenced, the following sentence was pronounced: "Upon complaint of the commons against the Viscount St Albans, lord chancellor, this high court hath thereby, and by his own confession, found him guilty of the crimes and corruptions complained of by the commons, and of sundry other crimes and corruptions of like nature; and therefore this high court having first summoned him to attend, and having his excuse of not attending by reason of infirmity and sickness, which he protested was not feigned, or else he would most willingly have attended, doth nevertheless think fit to proceed to judgment, and therefore this high court doth adjudge, That the lord Viscount St Albans shall undergo fine and ransom of 40,000*l.*; that he shall be imprisoned in the Tower during the king's pleasure; that he shall for ever be incapable of any office or employment in the state or commonwealth; that he shall never sit in parliament, or come within the verge of the court."

The only extenuation of Bacon's corruption, which has ever been attempted, is thus pleaded by Addison. "His principal fault seems to have been the excess of that virtue which covers a multitude of faults. This betrayed him to so great an indulgence towards his servants, who made a corrupt use of it, that it stripped him of all those riches and honours which a long series of merits had heaped upon him." This lame apology, feebly hinted at by the chancellor himself, deserves little notice. His connivance at the extortions of his servants was one of the corruptions charged on him; and his guilt will not be lessened by the supposition, that the support of their extravagance led him to all his other acknowledged acts of venality. To say that his unrighteous gains were not avariciously hoarded, but lavished on his unworthy dependents, or that want of economy had plunged him into difficulties, or that it is charity to wink at violations of justice, is to insult the moral feelings of mankind; and on the same principles we must excuse the depredations of every marauding chief, who shares the spoil with the partakers of his enormities. That the practice of taking presents had long prevailed in the court of chancery is not disputed; but it is scarcely credible, that former chancellors could have safely carried it on to the same immoderate extent, to which it appeared, on the trial, to have proceeded in a single year; and no precedent could form an excuse for such palpable baseness.

The sentence of the high court of parliament was not rigorously inflicted. After a short imprisonment, he was released from the Tower, and the other parts of his sentence were also remitted by the king, who granted him a pension of 1800*l.* a year. The remainder of his days was passed in contemplation. Though at the time of his fall he was sixty years of age, the vigour of his understanding, and the intensity of his application to study, were not in the smallest degree impaired. During the period of his humiliation, under the disadvantages of declining health, dejected spirits, and embarrassed circumstances, he employed himself in writing and revising those valuable works, which have, in a great measure, redeemed his name from disgrace, and placed him in the first rank of modern philosophers. He died at Highgate on the 9th of April 1626, from the effects of some incautious experiments on the preservation of bodies. He was buried in St Michael's church at St Albans, where a monument of white marble was erected to his memory. He is represented sitting in a

contemplative posture, and underneath is an inscription, written by Sir Henry Wotton, to the following purpose: *Franciscus Bacon Baro de Verulam, St Alb. Vic., seu notioribus titulis, Scientiarum Lumen, Facundia Lex, sic sedebat: Qui, postquam Omnia Naturalis Sapientia et Civilis Arcana evolvisset, Natura decretum explevit.*

The countenance of Bacon was strongly expressive, and his ordinary conversation indicated the quickness and universality of his talents. In his person he was of the middle stature, and his figure was good; but his constitution was by no means athletic. He had a spacious forehead, dark hair and eye-brows, a black penetrating eye, generally looking upward, a very grave cast of features, and a capacity of speaking like a master on every subject. "At one time, (says Osborn,) he would entertain a country lord, in proper terms, relating to horses and dogs; and at another time outcant a London surgeon." His opinions and assertions were received as oracles; but he always encouraged others to speak their sentiments, and, in repeating the observations which he thus drew forth, he never failed to clothe them with a new dignity and grace, and to enrich them with the additions of his own wisdom. Thus, (to use the words of his chaplain, Dr Rawley) "he would light his torch at every man's candle." A remarkable peculiarity in his constitution is gravely attested by the same biographer. "It would seem the moon had some principal place in the figure of his nativity; for she never was in her passion, but he was seized with a sudden fit of fainting, and that though he took no previous knowledge of the eclipse." He was married about the age of forty, to a daughter of Alderman Barnham, a lady of considerable fortune, by whom he had no progeny. In the discharge of his public functions, it is said, that he always acted with courteousness and humanity, or, as the king expressed it, "*suavibus modis;*" but there is too great reason to suspect that his urbanity was altogether artificial, and his affections cold and selfish. As a lawyer, he attempted to rival Sir Edward Coke, one of the greatest ornaments of the bench; and in point of eloquence, he was perhaps superior to that great man. Over his moral infirmities truth forbids us to throw the veil of silence. His grosser corruptions, which drew down on him the vengeance of the laws and the contempt of all honest men, are sufficiently blazoned in the page of English history. But it is perhaps equally mortifying to reflect on that deficiency of principle, that absence of ingenuous feeling, that tendency to dissimulation, that everlasting struggle to aggrandize himself by menial arts and beggarly importunities, and even by the more sordid instrumentality of detraction; all of which may be traced in the undoubted memorials of his private life, from the inauspicious moment when his father thought fit to direct his steps into the tortuous paths of political intrigue. To the early bias which he acquired in the train of an ambassador at the court of France, we are disposed to ascribe many of his future aberrations. It may seem harsh, to pronounce so freely concerning the abject disposition of a man whom posterity reveres. But he has taken care to perpetuate the remembrance of his own servility. We cannot accuse his biographers of having imprudently rifled the repositories of a departed friend, that they might add to the magnitude of his remains, by recording the garrulity of his private hours, and even the traces of his frailties. He bequeathed his letters and speeches to Dr Williams, bishop of Lincoln, (his suc-

cessor as lord keeper) leaving him at liberty to publish them; and this, according to his own account, he did in imitation of Demosthenes, Cicero, and Pliny, who carefully preserved their orations and epistles. Not content with writing a letter to this purpose, he thought fit to give his injunction greater solemnity, by inserting it in his will. What can be more disgusting than the fulsome parasitical flattery contained in his letters to the favourite Villiers? Who would believe that the immortal Bacon, at the age of fifty-five, was capable of bending so low as to profess it to be his greatest ambition to be the best servant of the king's stripling minion? His letters to this dissolute youth, when only in the dawn of his honours, are most elaborately written, and, as several copies of some of them, with considerable variations, have been preserved, it is evident that he made repeated attempts, before he could satisfy himself with the laboured compliments and specious pretences, by which he strove to make Villiers believe, that in forwarding his wishes, he would gain lasting honour to himself.

From this humiliating picture, we turn with satisfaction to review the unperishable monuments of Bacon's genius. In the intervals of his professional studies at Gray's Inn, he had conceived the design of a great undertaking, to the accomplishment of which he applied with incredible vigour, amidst the multiplied interruptions and dissitudes of a bustling life. We have already noticed his early dissatisfaction with the Aristotelian doctrines; and though he was not the first, who discerned the inutility of the scholastic logic as an instrument of discovery, he was certainly the first, who endeavoured to reduce into a methodical digest, the legitimate rules of philosophising. His first work, which in some degree unfolded his plan, was printed in 1605, and professed to treat "Of the Proficiency and Advancement of Learning." It was afterwards greatly enlarged and improved; and, having been translated into Latin by the Rev. George Herbert and some other scholars, was published under the well known title, *De Dignitate et Augmentis Scientiarum*. The important object which the author proposed was, to trace the boundaries of the sciences then known, to point out their mutual connections and dependencies, to exhibit a view of their relations to the different faculties of the human mind, to introduce a natural classification of their various branches, and to enumerate the defects and omissions in all the attempts made by former inquirers. According to Bacon, all the varieties of human knowledge may be ranged under history, poetry, and philosophy, corresponding to his division of the intellectual faculties into memory, fancy, and reason. He distributes history into natural and civil; poetry into narrative, dramatic, and parabolic; science into theology and philosophy; the latter relating to the Deity, nature, and man; which is merely a repetition of Aristotle's classification. An analysis of this work could convey no adequate idea of its value. Though debased by a considerable proportion of trifling matter, it contains many profound, acute, and original observations, and evinces an extent of erudition, a clearness of apprehension, and a solidity of judgment, which claim the highest admiration. A number of the particulars which he marks as *desiderata*, or as undiscovered regions in the world of science, are indeed more fantastical than solid; and it is greatly to be regretted, that the whole of the performance is obscured by a cumbersome load of un-

couth and affected phraseology. Thus he divides natural philosophy into the mine and the furnace, and the philosophers into pioneers and smiths, or diggers and hammerers; the former engaged in the acquisition of causes, the latter in the production of effects; the former speculative, the latter operative. Our limits do not permit us to enter into a critical examination of Bacon's arrangement of the sciences, against which it is easy to propose many objections; but no less exceptionable arrangement has hitherto been offered to the world.

The work which Bacon esteemed the chief of his writings, the *Novum Organum Scientiarum*, was printed in 1620, a short time before his fall. It was intended to supply one of the great defects which he had noted in the method of directing the human faculties, the want of a rational or inventive logic. His opinions on this subject are condensed into the form of aphorisms. Instead of the ancient method of syllogism, he proposed to conduct philosophical inquiries by what he called induction, in which we rise from an extensive collection of particular facts to general conclusions. He laid down a series of rules for making observations and conducting experiments. But the most essential service which he has rendered to science, is the investigation of those causes of false judgment, which are most intimately connected with the natural and acquired dispositions of the mind. These sources of error he has numbered under four heads, which he calls *idola tribus*, *idola specus*, *idola fori*, and *idola theatri*; by which terms he means the prejudices arising, 1. From the original and universal dispositions of the human mind; or, 2. From the peculiarities of individual constitutions and habits; or, 3. From the imperfections and abuses of language, the medium of communication between man and man; or, 4. From the attachment to prevalent theories and erroneous rules of judging. The object of the whole work was, to reclaim men from the devious and intricate paths in which they had long wandered, to the sound and profitable application of their understandings. Its principal fault is the obscurity resulting from the want of illustrations; a fault not chargeable on the author, who could not be expected to invent specimens of a mode of proceeding hitherto little cultivated. James I. said of this book, that it was like "the peace of God, which passeth all understanding."

These works formed the two first parts of the plan, to which the author gave the name of *Instauratio Magna*; the first containing a distribution of the sciences, and the second unfolding a mode of procedure in the interpretation of nature. His plan embraced four other objects, for the accomplishment of which he had thrown together many detached hints under various titles. His third object was to prepare an arrangement of the phenomena of the universe, with a view to establish natural philosophy on the basis of observation and experiment. The execution of this object was attempted in his *Sylva Sylvarum*, a work of very indifferent merit. The fourth part of his labours, which he called *Scala Intellectus*, he intended to devote to a progressive series of inquiries, containing a detailed exemplification of his method in the various sciences. The fifth part, denominated *Prodromi, sive Anticipationes Philosophiæ Secundæ*, was intended as a temporary disposition of his materials till there was leisure to complete the whole structure, by the addition of the sixth part, which he called *Philosophia Secundæ, sive Scientia Activa*, to

which all the other steps were preparatory. This ultimate object of all his labours was to establish a system of philosophy on the severe and chaste principles of experimental research; but he had not the temerity to expect that he would ever be able, personally, to conclude this arduous task.

What his lordship did accomplish was unquestionably a vast accession to the progress of the human mind; but his merit is probably overrated by many, who know little of the real value of his writings. The minds of men had been gradually preparing to cast off the yoke of authority. The revival of letters in the 15th century, the invention of printing, the reformation of religion, and various other causes, had introduced a freedom of discussion, over which the doctrines of the schools had little controul. Individuals had sprung up in different kingdoms, who had the hardihood to revolt from the dogmas of Aristotle; and others, who, by devoting themselves to experimental inquiries, had demonstrated the fallacy of many opinions hitherto deemed infallible. John of Salisbury, Grosthead bishop of Lincoln, Roger Bacon, Occam, Erasmus, Ludovicus Vives, Faber, and even Paracelsus, Montaigne, and Bruno, as well as Luther and his coadjutors, had taught men to question the decrees of the Lyceum, and to set at nought the thunders of the Vatican. Dr Gilbert had ascertained the laws of magnetic action, and furnished an admirable specimen of the inductive method. Copernicus had discovered the true theory of the planetary revolutions; a theory which Bacon impotently endeavoured to refute. Other eminent men, contemporary with Bacon, and unaided by his writings, particularly Galileo, Kepler, and Gassendi, were pursuing a course similar to that which he delineated, and acquiring immortal fame by improvements in geometry and physics, of which sciences he had scarcely learned the rudiments. It must not be disguised, that Bacon had never formed a fair estimate of the praise due to his predecessors and fellow-labourers. His *Censure of the more Eminent Philosophers* is expressed in the most acrimonious strain of scurrility. He was too ambitious of innovation, and too fond of paradox. In violation of his own rules, he often assumed facts without sufficiently scrutinising the evidence on which they rested, or sometimes without any examination at all; and very frequently, in his attempts to account for facts, he negligently acquiesced in hypothetical principles, which had obtained a popular currency. His distinctions are often perplexed, or indefinite, particularly with regard to physical and metaphysical science. His language also is destitute of precision, being extravagantly metaphorical, and also replete with unnatural conceits and obscure allusions. It is much more reprehensible than Aristotle's, which he has blamed for abounding with new words. Lord Bacon professes to retain the ancient terms, but to alter their uses; a practice which is apt to puzzle and mislead ordinary readers. With all these faults, and others on which it might seem invidious to dwell, Bacon must be allowed the merit of having bequeathed to the world a larger and more precious mass of sound logical instructions, deduced from his own reflections, than are to be found in the writings of all the authors who preceded him.

Of his English productions it is unnecessary to say much. His *Essays* have obtained a considerable share of popularity; but the observations contained in them, though frequently just and striking, are not always very

consistent with one another. His speeches, law tracts, and historical or political papers, are heavy and uninteresting compositions, containing many specimens of bad taste and spurious wit, interspersed occasionally with useful and profound remarks. The treatise on the *Wisdom of the Ancients* is ingenious, but extremely whimsical and puerile. His *Aphorisms* are not of higher dignity than *Joe Miller's Jests*; indeed, the one book appears to be the prototype of the other. His *Letters* have neither ease nor dignity; and the greater part of them are full of teasing solicitations for preferment.

Lord Bacon professed a great veneration for religion. Some theological disquisitions, and sacred meditations, are found among his remains; and one of his prayers has, with little discrimination, been applauded by Addison as if it rivalled the devotion of an angel. His *Christian Paradoxes* are so extravagantly expressed, that Bolingbroke has adduced them as proofs of his insincerity rather than of the strength of his faith. But of all his devotional exercises, his versions of some of the Psalms are the most despicable. The following notable passage from the 104th Psalm, versified by the chancellor of England, the contemporary of Spenser and Shakspeare, cannot be matched by the sorriest rhymes of Hopkins and Sternhold:

The fishes there far voyages do make,
To divers shores their journey they do take,
There hast thou set the great Leviathan,
That makes the seas to seeth like boiling pan.

With regard to his style, it is generally harsh and inelegant, evidently laboured with extreme care; often obscure or affected, but more frequently nervous and emphatic. His eloquence, according to Ben Jonson, was irresistibly impressive, and pleasing.

We now close our observations on the character and works of Bacon, a man, whose mind, indefatigably active, was capable of the mightiest efforts; whose powerful imagination suggested to him many original views; and whose literary ambition urged him to the bold attempt of demolishing the fabric reared by Aristotle, and rebuilding science on a more impregnable foundation. While the story of his public life affords a salutary memorial of the ravages effected by inordinate ambition, the perusal of his philosophical labours tends to abate the keenness of our scorn, and to mingle admiration and gratitude with the sympathies claimed by fallen greatness. We would earnestly recommend the *Novum Organum* to the attention of all speculative men, as one of the best means of facilitating and guiding their inquiries. From want of acquaintance with this excellent auxiliary, many ingenious men, in the present day, proceed empirically in their investigations, as if rules were altogether superfluous, or at least as if they were not aware that any code of rules exists preferable to the random suggestions of imagination.

The best edition of the treatise *De Augmentis* was published in 1623, under the author's inspection. A very accurate edition of the *Novum Organum* was published in 1620. The whole works of Lord Bacon were edited by Blackbourne, in four volumes folio, London, 1730; and by Mallet, London, 1740, also in four volumes, folio. The most complete editions are, one in five volumes, quarto, London, 1778, and one in ten volumes octavo, London, 1802. There is a book in three volumes quarto, entitled, *The Philosophical Works of Lord Bacon, by Dr Shaw*; but its accuracy is not to be relied upon. Some other translations and abridg-

ments appear to be still less correct. See Rawley and Mallet's *Life of Bacon*. Rushworth's *Historical Collections*. Voltaire *Melanges de Littérature*. *Journals of Parliament*, 1621. Birch's *Memoirs of Elizabeth*.

BACON, JOHN, an eminent English sculptor, was born in the year 1740. His father, who was a cloth-worker in Southwark, was descended from an ancient family in Shropshire. Though, in the age of childhood, Bacon discovered a propensity for drawing, his first opportunity of exercising it was on becoming an apprentice at a porcelain manufactory, at the age of fifteen. There he was employed in painting china, and in forming small ornamental pieces in clay, which betrayed early indications of that genius which afterwards led him to such celebrity. The sight of the models of different sculptors, sent to a pottery near the manufactory to be burnt, excited a great desire in Bacon to make something similar to them; and, in the year 1758, he formed a small figure of Peace, after the antique. In 1763 he first tried the sculpture of marble, without previously having seen it attempted; and then he invented a useful instrument, since adopted by many others, for the purpose of obtaining correct measurements and proportions. The progress of this artist was so rapid, that, between the years 1765 and 1766, he obtained no less than nine different premiums from the Society for Encouragement of the Arts. The Royal Academy being instituted in 1768, Bacon attended it, and received what may be called his first instructions in sculpture, having never before seen either it or modelling regularly executed. In the following year, the gold medal, the first ever given for sculpture by the Academy, was decreed to him. He was soon afterwards elected a member of the Academy; and his reputation was further established by a statue of Mars, which introduced him to the notice of the Archbishop of York. Bacon was now employed to model a bust of the king; on which occasion, having answered his majesty's question, whether he had ever been out of the kingdom, in the negative, "I am glad of it," said the king, "You will be the greater honour to it." The king was so well satisfied with this performance, that he ordered Bacon to prepare another bust of him, intended as a present to the university of Göttingen, and the queen ordered a third.

By this time the reputation of Bacon as a sculptor and modeller was firmly established. In 1773, after executing two statues, of Mars and Venus, in plaster, he presented them to the Society for the Encouragement of Arts: they were received with much approbation, and the society voted him their gold medal, inscribed EMINENT MERIT. He was now employed in many sculptures: He executed two groups for the top of Somerset House, in London, in 1780, and the monument of Lord Halifax in Westminster Abbey. Next year he began the famous statue of Judge Blackstone, for All Souls College, Oxford, and soon afterwards that of Henry VI., for the Anti-Chapel at Eton. He then finished what has been considered his *chef d'œuvre*, the monument of the Earl of Chatham in Westminster Abbey, which was commenced in 1773. His skill in the antique had been frequently called in question, but he modelled a head of Jupiter *Tonans*, which was inspected by several eminent connoisseurs, and mistaken for an antique; some even inquired, "from what temple abroad he had obtained it?" Numerous pieces of sculpture were produced from the chisel of Bacon. Lord Rodney's monument at Jamaica, Lord Heathfield's at Buck-

land, near Plymouth, Mr Howard's and Dr Johnson's in St Paul's Cathedral. This artist was attacked by a disease, which quickly terminated his existence, in 1799.

Bacon was certainly one of the most distinguished sculptors whom England has produced: There is an invention, a variety, and appropriate distribution of his characters, which proves that his conceptions were no less just than his execution. It was considered surprising, that one who had never studied abroad should be able to produce what the best stile of sculpture has seldom excelled; a fact which shews, that real genius, if duly fostered, will always soar paramount to mere imitation. In competitions with rival artists, Bacon was remarkably successful: He failed only once in sixteen trials. Besides statuary, he is said to have turned his attention to poetical composition, and to have written on subjects connected with the arts. He also afforded materials and observations for treatises on sculpture. Simplicity of manners in domestic life, and piety, eminently characterised him. Though he had sculptured many splendid monuments for others, he ordered his own grave to be covered only with a plain stone, inscribed, *What I was as an artist seemed to me of some importance while I lived; but what I really was as a believer in Christ Jesus is the only thing of importance to me now*. See Cecil's *Life of Bacon*. *Gentleman's Magazine* 1799. Dallaway's *Anecdotes of the Arts in England*. (c)

BACOPA, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY. (w)

BACTRIA was a kingdom of Asia, which, in ancient times, appears to have been distinguished by the extent of its territories, the number of its inhabitants, and the magnitude of its exploits. But the glory which the Bactrians merited, by the wisdom of their councils, and the valour of their arms, has been obscured in the depths of remote antiquity; and the exalted station which their sages and heroes might hope to obtain on the page of history, has been occupied by the more fortunate candidates for fame which future ages have produced. Acquainted, as we are, with the uncertainty and contradiction of ancient annalists, it is with some hesitation that we attempt to mark the limits of this dynasty, which, being nearly the same with modern Chorasán, appears to have been separated, on the south, from India, by the lofty summits of the Paropamisus; on the west, from Margiana, by the hills which surround that province; on the north, from Sogdiana, by the river Oxus; and, on the east, from Asiatic Scythia, by a chain of mountains which rises as a barrier between the two countries. After employing some investigation, we imagine there are reasons for concluding, that this country was first peopled by the descendants of Gomar, the grandson of Noah, and that, for some time, they were called Chomarians, and their metropolis Chomara, appellations derived, with very little corruption, from the name of that patriarch. Afterwards Bactria became the capital of the kingdom; and, if we believe Q. Curtius, both the kingdom and its capital were denominated from the river Bactrus, which fertilized the fields through which it rolled, and washed the walls of that famous and almost impregnable city. But though we are inclined to follow Curtius, yet we are not ignorant, that the name of the river upon which Bactria was built, according to Pliny, was Zariaspa, and, according to Ptolemy, Dargidus. It will not, however, be impossible to

reconcile the accounts of Curtius and Pliny, if what the latter affirms be allowed, that the ancient name of Bactria was Zariaspe, which is also affirmed by Strabo. In the same manner the river, upon which the city was built, may have also changed its name, or borne different names in different countries. Ptolemy's account, however, is inconsistent with both; for he places the city in the interior of the kingdom, while they assert that it was situated at the foot of the Paropamisus, the southern boundary of the country. Bactria, in latter ages, was called Balk, a name which it bears at the present day.

At what time Bactria assumed the name and the glory of an independent kingdom it is impossible to determine. If we admit the authority of Ctesias, which we have more than questioned in our account of Assyria, it must have been at a very early period. According to him, Oxyartes filled the throne of Bactria, when Ninus and his Assyrians endeavoured to reduce all Asia under their power.* But though the progress of that monarch, to the universal empire of the East, was long checked by the wisdom and valour of the Bactrians, yet the walls of this capital, and the spirit of its inhabitants, yielded at last to the repeated attacks of their numerous foes, and that kingdom became a province of the Assyrian empire. It is inconsistent with our plan to relate the various wars in which the Bactrians, as auxiliaries, engaged, while their governors were appointed by their conquerors. In this state of degrading dependency, Bactria remained, till the Assyrian empire was itself overturned by the aspiring spirit and the fortunate arms of Cyrus the Great. To conduct that consummate warrior at the head of the confederate forces of Media and Persia, till the ascendancy of his genius extinguished the glories of the Lydian and the Assyrian empires on the field of battle, and levelled the walls of Babylon with the ground, belongs to the historian of these nations. But though the Bactrians might rejoice, that the kingdom which reduced them to bondage was thus reduced to the same humiliating dependency, yet, under the yoke of the Persians, they were still doomed to wear the fetters which the Assyrians had first forged for them, and they soon found that they had changed their masters, but not their state. The names of the governors of Bactria, under Cyrus and his successors, are unworthy of a place in the page of history; and our attention is not drawn to the subject which we are treating till the time of Darius Hystaspes. During the reign of that monarch, according to the most authentic accounts, flourished Zoroaster, the great restorer of that religion which bears his name, and which has extended its influence, not only over Persia, but over almost all the East. After he had established his opinions in Media, where, as we shall narrate in our account of that kingdom, he first assumed the character of a divine teacher, he migrated into Bactria, and there propagated his opinions with singular success. It was in the capital of this country that he fixed his chief residence, and con-

secrated to the worship of fire that magnificent temple, to which every true disciple was bound to make a pilgrimage, once in his life, to propitiate the deity which in a peculiar manner resided there. Having accomplished several journeys into the neighbouring nations for the propagation of his doctrines, he returned to Bactria, where, according to his own institutions, he was principally to reside, and endeavoured to convert Argasp, king of the Oriental Scythians, not so much by the force of reason, as by the dread of the arms of Darius. The indignation of that high spirited monarch was roused against a man, who thus dared to insult his understanding and his power, and at the head of his native bands he invaded Bactria, slew Zoroaster, and the priests who adhered to him, and destroyed all the temples which he had consecrated. Had he returned to his own country in safety, his triumph would have been complete; but before he could reach his dominions, he was overtaken by Darius, and was doomed to behold his forces annihilated by the Persian arms. Darius immediately, by his example and authority, restored the temples, and confirmed the religion of Zoroaster in Bactria.

Under the dominion of Persia, Bactria remained till the reign of Darius III. surnamed Codomannus. When that monarch beheld his mighty army dissipated, on the plains of Arbela, by the consummate skill of Alexander the Great, and the irresistible valour of his hardy veterans, he fled from the last and the most disastrous of his fields to Media, where, collecting the wrecks of his conquered forces, he resolved to make another effort to prop his falling fortunes. But when he heard that Alexander was advancing to give him battle, he shrunk from the unequal contest, and determined to retire into Bactria, to augment his army with the brave inhabitants of that province. Bessus, a Persian nobleman, to whom the government of that province was committed, was then in the army of Darius, at the head of the Bactrians, consisting of 4000 slingers, and 3000 horse. When he perceived that the spirit and the power of Darius yielded to the rising fortunes of the Macedonian hero, instead of supporting his lord and benefactor, he formed a conspiracy against him, and hoped to rise on his ruins to the empire of the East. No sooner did the Persian prince set out from Ecbatana, than, dead to gratitude and justice, and regardless of future fame, Bessus seized the person of the unfortunate monarch, and carried him to Bactria. Finding, however, that he was pursued by Alexander with implacable resentment, he put Darius to death, assumed the sovereignty of the East, and collected an army to defend his throne. But though, to excuse his treason, and to advance his ambition, he had formerly condemned the flight of Darius, and imputed the misfortunes of that monarch to his pusillanimity, yet he now trembled at the approach of Alexander, imitated the most indefensible part of Darius's conduct, destroyed the country through which his enemies had to pass in pursuit of

* Justin, in the first book of his History, informs us, that Zoroaster was king of Bactria, when Ninus invaded that kingdom, (*Ninus bellum cum Zoroastre rege Bactrianorum fuit.*) Before this assertion can be admitted, all the land marks of ancient history must be removed. Yet such is the discernment of some writers, that this assertion has been believed. Euseb. in *Chron. Diog. Laert. in Proemio.* The truth is, Zoroaster did not live till many ages after, as all the oriental writers assert, such as Abulfaragius, Ishmael, Abulfeda, Sharastani, &c. Ligerius, however, informs us, that in some ancient manuscripts of Justin, Oxyartes is found instead of Zoroaster, which, in all probability, was the true reading. Some ignorant transcriber may have changed the name, because he found in the text, that the king mentioned was said to have been the first inventor of magic arts, (*primus dicitur artes magicas invenisse,*) and as the invention of this science has been commonly attributed to Zoroaster, he might imagine that he was restoring or correcting the text of Justin, when he was corrupting it. We may easily perceive, that Oxyartes, if he ever existed, might have been addicted to these arts long before Zoroaster was born: for Zoroaster, though the great restorer of magic, was by no means its founder.

him, transported his army over the Oxus, and, after burning his vessels lest they should fall into the hands of Alexander, fled to Nautaca, a city of Sogdiana, where he imagined he would be secure. But neither the ravages of Bactria, nor the breadth of the Oxus, nor the bulwarks of Nautaca, could protect the usurper. Bessus was delivered into the hands of Alexander by his own officers, when they could no longer defend him; and Alexander, detesting the traitor, though he reaped the harvest of his treachery, yielded him to the revenge of Oxatres, the brother of Darius, and the regicide expiated his crimes by a death embittered with every torture which ingenuity could invent, or cruelty execute.

The conquered kingdoms, which formed the extensive empire of Alexander, were united only by the terror of his arms. At his death the chain was broken, and the chiefs, who governed the provinces by his authority, aspired at independence, and each claimed the sovereignty of his own state. Diodorus Siculus advances Philip to the throne of Bactria at that time; while Justin gives the sceptre to the hand of Amyntas. But the Bactrian prince, whatever was his name, was not long able to vindicate the fame and the freedom of his country. Seleucus, who had ascended the throne of Syria, having gained possession of Babylon, and subdued Media, carried his victorious arms into Bactria, and again reduced it to slavery. In this state of degradation the nation groaned, till Antiochus Theos gave the government of the province into the hands of Theodotus, a man not more distinguished by the greatness of his ambition, and the magnitude of his designs, than by the wisdom and valour which he displayed in accomplishing them. Perceiving that his master was engaged in a bloody war with Ptolemy Philadelphus, king of Egypt, and that all the resources of his kingdom were employed, he determined to shake off his allegiance, and vindicate the freedom of the country which he governed. We may reasonably conclude that, preparatory to the discovery of his great design, he employed his administration to establish the discipline and power of his army, to promote the cultivation and prosperity of his country, and to repair the fortifications of its cities. But we shall hesitate to believe, upon the authority of Justin, that the kingdom which Theodotus claimed could boast of a thousand cities; yet certainly whatever were the energies of that country, they were employed with singular ability by the illustrious usurper. His example was followed by many of the neighbouring states, which revolted from the power of Antiochus, and, deriving confidence and assistance, each from the success of the others, gained the liberty at which they aspired. The martial virtues, which enabled Theodotus to take possession of the kingdom, preserved it in his hand during the remainder of his life, and, at his death, placed the crown upon the head of his son.

This prince inherited the name as well as the dominions of his father. He began his administration by forming an alliance with Arsaces, who had wrested Parthia and Hyrcania from the Syrian yoke. But though, by this means, he secured himself from the attacks of Antiochus, and considerably extended the limits of his kingdom, yet he yielded to the superior abilities of Euthydemus, who aspired to the sovereignty of Bactria, and who, at the head of his bold and determined adherents, submitted his pretensions to the decision of the sword. Theodotus had the misfortune to behold the best blood of his army shed in his cause; and in order

to save his life, but not his honour, he fled from the field of battle, and from his dominions, and his victorious rival ascended the throne. But though the wisdom which Euthydemus displayed might have bent his valour to endure, if not to enjoy, the tranquillity of peace; yet we may be assured, that his brave and aspiring spirit, equally formed for counsel and for action, was not displeased when the defence of his country again summoned him to the field of fame. Antiochus, having made peace with Parthia, was still indignant at the revolt of the Bactrians, and, with all the forces of his mighty empire, endeavoured once more to reduce them to subjection. But in a long and bloody war, which was chequered with various success, Euthydemus proved that he was worthy of the crown, which he owed not to his birth, but to his ambition; and that all the efforts of Antiochus would be unable to wrest the sceptre from his hand. But as kings should resort to war only to procure peace, the moment when he understood that Antiochus despaired of success, he sent ambassadors to that monarch. Being admitted into his presence, the picture which they drew of the calamities of war, of the resources of their monarch, and, above all, of the designs of the Scythians, who were then rejoicing at their mutual destruction, and preparing a mighty army to overwhelm whichever of them should at last gain the ascendancy, had such an effect upon the mind of Antiochus, that he immediately consented to a peace, which was confirmed by the marriage of the son of Euthydemus and his own daughter.

But the throne of Bactria, which was thus established, did not, at his death, descend to the son, but to the brother of Euthydemus. Menander, who, however, assumed the government in the name of his nephew, as soon as he had secured his authority, longed to signalize his reign on the field of battle, and, at the head of his forces, passed the river Hypanis, and extended the boundaries of his dominions, by subjugating the kingdom of Sigertis, the extensive province of Pattalena, and some other eastern countries. Proud of past victories, and meditating victories to come, he was arrested by the hand of death when just ready to invade Syria. So much was he beloved by his subjects, that the principal cities of Bactria were in arms to claim the honour of his sepulchre, and, to prevent a civil war, his ashes were divided amongst them, and the magnificent monuments which they raised perpetuated the memory of his fame, and of their affection. Demetrius, the son of Euthydemus, then ascended the throne. The wisdom and vigour of his administration proved, that he was not unworthy of the sceptre which had been wielded by the martial talents of his uncle, and he not only secured the conquests of his predecessor, but added to them several new provinces, and raised his kingdom to the summit of prosperity. He left his dominions to his son Eucratides, who, pursuing the career of victory which his father had marked out for him, burst, with the whole force of his empire, through the barriers which nature seemed to have placed between his dominions and India, and kindled the flames of war in that country. The dangers which he encountered, and the defeats which he sustained, at the beginning of his enterprize, seemed to detract as much from the wisdom of his counsels, as they added to the fame of his valour; and it is difficult to determine, whether we ought more to blame the temerity of that prince, who could rashly expose himself, with only three hundred soldiers, in an enemy's country, to

be besieged by an army of forty thousand men, or to admire the consummate skill, and the undaunted courage, by which he could not only extricate himself from such perilous circumstances, but obtain a victory over the besiegers. This victory was only the prelude of future conquest: many extensive provinces in the interior of India were subdued, and the glory of his exploits vindicated his claim to the proud appellation of *The Great King*, an appellation which the monarchs of Persia wished to arrogate to themselves, when exalted to the sublimity of empire. Returning to his paternal dominions, his son, who bore his name, and to whom he had committed the administration in his absence, conspired against his life, insultingly drove his chariot over the mangled body of his father, and inhumanly denied his remains the rites of sepulture.

Eucratides II. gained a kingdom by the murder of his father, but the vengeance of heaven pursued the parricide. While he was preparing to resist the Parthians, who were invading his dominions, a numerous and hardy band of barbarians, issuing from the inhospitable wilds of Scythia, passed the river Jaxartes, poured over the four kingdoms of Bactria with irresistible violence, rolled the forces of Eucratides before them, and expelled the monarch from his dominions. Collecting, however, another army, and endeavouring to rouse his countrymen to assert their liberty, Eucratides returned to the doubtful contest; but on the field of battle, where he lost his life, the glories of his country were finally extinguished, and Bactria was precipitated into slavery, from which it has not emerged to the present day. The power of Scythia, under which Bactria groaned for ages, was at last broken by the Huns; but as this warlike people conquered that unhappy country for themselves, and not to exalt it to its former rank amongst the nations of Asia, that revolution does not fall within the range of our rapid narrative.

By Herodotus, and other ancient annalists, we are informed, that the Bactrians were well made, vigorous and healthy; admirably adapted for supporting the fatigues and dangers of war, by the habitual temperance which they cultivated, and by that restless activity which disdained repose. Their soldiers were deservedly famous for the skill which they displayed in the use of the sling and the bow, with which they levelled the ranks of the enemy at a great distance. As they drew near to battle, they employed short darts, till, joining man to man, the slaughter which they made with the sword, or with a large dagger that hung from their girdles, evinced that the strength of their arm, and the valour of their soul, were equally formed for close combat. Their government was monarchical, hereditary, and despotic. Their religion was idolatrous; for though they held the opinion of one Supreme God, yet the adoration which they paid to the sun, and to fire, even after Zoroaster had reformed their theology, will warrant this conclusion. We shall not have a very exalted idea of their morality, when we are informed, that incontinence was not accounted a blemish even in the female character, that incest was permitted, and that the finer feelings, which dignify human nature, and are the source of the purest pleasures of our existence, were so completely eradicated from their hearts, that they trained fierce mastiffs to devour their aged parents, when they could no longer support themselves, and which, from that horrid employment, were emphatically denominated *Sepulchral dogs*. Their learning, however, during the latter period of the

state, appears to have been considerable; and it is, perhaps, more than a conjecture, that from this country the rays of science first dawned upon the Hindoos. During the same time, they seem to have cultivated commerce to a great extent with the various nations of India. They wore tiaras, tunics, and breeches, like the Medes.

Perhaps no country of the same extent ever discovered a greater variety of soil than Bactria. The northern provinces, which extended along the banks of the river Oxus, were intersected with many streams and fountains, which adorned and fertilized the fields. The ancient topographers of this country, whose account is confirmed by Sir John Chardin, inform us, that there is a fountain in Bactria, whose waters are so pleasant to the taste of the musaliman, or albemice, a fowl about the size of a hen, and of a black and red colour, that it attracts it to its streams from a great distance. As this fowl is gregarious, and feeds upon locusts, whenever these insects settle upon any fickle in such numbers as to endanger the crop, the inhabitants convey the water of this fountain in vessels to the place, and the flocks of musalimans, which are immediately drawn thither, deliver the country from the locusts. Bactria could boast of many extensive plantations; vines, and other fruit-trees, were in great abundance, and the crops which they produced were not only liberal, but of an exquisite taste and flavour. That species of tree which produced manna of a yellowish colour and of a large size, and which was allowed to be the most valuable, grew to greater perfection there than in any other country. The fields were equally well adapted for every species of grain; and the flocks and herds which ranged their pastures were all excellent in their kind. The goats of this country are said to have produced the best kind of bezoar, a stony substance which is formed within the animal, and is so famous in the annals of medicine. The southern regions of this country, however, being in a great measure destitute of water, and covered with sand, are equally remarkable for their sterility. The whirlwinds, which with irresistible violence sweep along the surface, not only blot out every vestige of the roads which lead through these regions, and bury the unhappy travellers with the clouds of sand which they roll before them, but with their continued eddies raise lofty mountains on the plains. Travellers, whom necessity compels to traverse these pathless wastes, generally journey by night, which from the brightness of the sky resembles day, and direct their course by the stars, as if they were at sea. BACTRIS, a genus of plants of the class Monœcia, and order Hexandria. See BOTANY. (x)

BADAJOZ, the *Pax Augusta* of the Romans, is the capital of Spanish Estramadura. The town was formerly situated on the high ground where the castle now stands, and the splendour and extent of its buildings are still apparent in the deserted churches, and in the remains of Roman, Gothic, and Moorish architecture, which mark its ancient site. The modern town is situated on the lower ground, and extends into a beautiful plain on the banks of the Guadiana. The cathedral is the only public edifice deserving of notice, and some of the chapels are adorned with excellent painting.

The town has five gates, and the streets are narrow and irregular. Without the gate of Las Palmas there is a fine bridge over the Guadiana, built in 1596, and containing 28 arches, the largest of which has a span of 78 feet, and the smallest of 20. The length of the bridge is 1874 feet, and its breadth 20.

Being one of the frontier towns of Spain, and nearly about a league and a half from Portugal, Badajoz is defended by strong fortifications, and by the castles of Christobal and Las Pardaleras. It was conquered by the Goths in the fifth, and by the Moors in the eighth century, and has undergone numerous sieges in subsequent wars.

Badajoz is the residence of a captain-general and intendant of the province of Estremadura, of a military and civil governor, a military governor of the castle of Christobal, an Alcade mayor for administering justice, and a principal contador of war. It has also an arsenal called La Maestranza, which contains all kinds of arms and military engines.

Badajoz is the seat of a bishop, suffragan of the metropolis of San Jago; and there are in the town five parish churches, seven monasteries, five nunneries, and five hospitals.

The only manufactory in this city is one of hats, which was established a few years ago by a Frenchman. Population 14,500. West Long. $6^{\circ} 43'$, North Lat. $38^{\circ} 44'$. See Laborde's *View of Spain*, vol. i. p. 556; and Semple's *Second Journey in Spain*, p. 28. (τ)

BADEN, a margravate of Germany, in the circle of Swabia, situated on the eastern bank of the Rhine. It comprehends the territory which lies between the rivers Pfiz and Swarzback, and is watered by the Eus, the Wurm, the Nagoed, and several other tributary streams of the Rhine. It is divided into two marquises, which were formerly named the marquise of Baden-Baden, and marquise of Baden-Durlach. But since the union of these states under one prince, they are merely distinguished by the names of the Upper and the Lower marquise. The Upper marquise, of which Baden is the capital, comprehends the northern part of this country, situated between the rivers Pfiz and Alb; all the rest of it is included in the Lower marquise, the capital of which is Durlach. Besides these two cities, the principal towns are, in Upper Baden, Rastadt, Stolboffer, Steinbach, and Etlingen; and, in Lower Baden, Carlsruh, Pforzein, Muhlburg, and Emmingen.

The country of Baden is fertile and beautiful. Its streams are shaded by forests of excellent wood; its fields wave with luxuriant crops of corn, hemp, flax, and hay; while its orchards abound with the finest kinds of fruit; and rich clusters of grapes are seen hanging from its vines. Numerous herds of deer range among the woods and mountains, which are likewise frequented by large flocks of wild fowl. The meadows, irrigated by the Rhine, pasture great numbers of horses and black cattle; the hogs, fed upon chestnuts, furnish bacon of a delicious flavour; and valuable fisheries are established on the islands of the Rhine. The mines of Oberweilli and Canderon produce excellent iron; and quarries of free-stone, and various kinds of marble, are also found in this country, as well as agates, which the inhabitants polish and export in considerable quantities. Manufactures are much encouraged in Baden, and are in a very flourishing condition. Among others, there is at Durlach a manufactory of that kind of varnished

pottery which is called Fayenza, from a town in Italy where it was first invented. The margrave has established at the same place, a few years ago, a fine manufactory of clock-work, of which a particular description will be given under the article DURLACH.

The margrave of Baden is a sovereign prince, and has two votes in the college of princes; one for Lower Baden, and the other for the margravate of Stockberg, which is situated along the Brisgaw. His territories are said to be 832 square miles in extent, and to contain 200,000 inhabitants. His whole revenue amounts to 1,200,000 florins, or about 120,000*l.* sterling; but as the reigning prince has been occupied for many years in improving his finances, suppressing arbitrary imposts, and substituting in their stead a regular land tax, his revenue will, without doubt, be considerably increased. The military establishment of Baden consists of 3000 men, 500 of whom are cavalry. The reigning prince, and his subjects in general, are Lutherans; but other sects are tolerated. (μ)

BADEN, the capital of the Upper marquise of that name, is situated on the river Oelbach, at the foot of a mountain covered with vineyards, near the Black Forest. It is celebrated for its hot baths: they are supplied by boiling water issuing from twelve springs, which the inhabitants convey by subterraneous pipes to almost every house. N. Lat. $48^{\circ} 46'$, E. long. $9^{\circ} 24'$. (μ)

BADEN, a small town in the archduchy of Austria, seated on the river Schwocha, and much frequented on account of its baths. N. Lat. $48^{\circ} 3'$, E. Long. $16^{\circ} 12'$. (μ)

BADEN, a county of Switzerland, lying on both sides of the river Limat. It is bounded on the north by the Rhine; on the east by the canton of Zurich; on the south by the Reuss; and on the west by the Aar and the canton of Bern. This county is fertile in corn and fruits, and vines grow in some places along the banks of the Limat. Its extent is about 158 geographical square miles; it has three large towns, a borough, and several villages, and contains about 24,000 inhabitants. About the 10th century, Baden was incorporated in the German empire; and, after being successively subject to the dukes of Zæringen, the counts of Kyburgh, and Rodolph of Hapsburg, the canton of Zurich obtained possession of it in the year 1413, and made it a bailliage of the eight ancient cantons, Lucern, Uri, Schweiz, Underwalden, Zug, Bern, Uri, and Zurich. Thus it continued till the civil war broke out between the Protestants and Catholic cantons, (A. D. 1712.) It was then seized by the troops of Zurich and Bern, and at the peace of Araw was ceded to those two cantons and Glarus, which, having remained neuter, preserved its right of joint sovereignty. Till this time the diet had always assembled at Baden, but it has since been transferred to Frauenfeld. The three cantons alternately appointed a bailiff, who resided in the castle of Baden, the capital. The inhabitants enjoy the right of electing their own magistrates, and have their own judicial courts. In civil proceedings an appeal lies to the bailiff, and from his decision to the syndicate, composed of the deputies of the three cantons, and, in the last resort, to the cantons themselves. In penal causes the criminal court condemns, and the bailiff has power to pardon, or to mitigate the offence. By a decree of the French government, in 1801, Argovie, united with Baden, and the upper part of of the Frickthal, was made

one of the 17 departments, or cantons of Swisserland, from which 6 representatives were to be deputed to the diet. (μ)

BADEN, the capital of the above canton, stands on the bank of the Limat, which there flows through a plain flanked by two hills. Its hot baths, from which it derives its name, are much frequented, and were famous even in the time of the Romans, by whom they were called *Aqua*, or *Therma Helveticæ*. Baden was originally a Roman fortress, erected for the purpose of checking the Germans; and still retains many monuments of Roman antiquity, such as alabaster statues of several heathen gods, bronze coins, and medals of the emperors, made of gold, silver, copper, and bronze. There is a stone pillar too, erected in honour of the emperor Trajan, who paved in this country a road eighty-five Italian miles long. The baths are about a quarter of a league distant from the city, and their waters, which are mixed with sulphur and alum, are conveyed to the houses by means of pipes. N. Lat. $47^{\circ} 21'$, E. Long. $8^{\circ} 12'$. (μ)

BADENOCH, a district in the county of Inverness in Scotland. See **INVERNESS-SHIRE**.

BADGER. See *Ursus*, under **MAMMALIA**.

BADINAGE, the name given in France to a method of hunting wild ducks, practised in some parts of that country, and which M. Gerardin, one of the authors of the *Dictionnaire des Sciences Naturelles*, describes as very amusing. The sportsmen provide one or more boats, which they cover with green boughs, or green reeds, and row, as silently as possible, along the pond, or lake, which the ducks frequent. They have also a little dog, trained to the sport, whom, as they approach the ducks, they slip unobserved into the water. The ducks, who were dispersed here and there on the surface of the water, no sooner perceive this unexpected intruder, than they collect themselves together, and endeavour to escape to another part of the lake. Pursued by the dog, and attracted by the appearance of the green boughs, or reeds, they swim for refuge to these insidious islands. The sport now begins; for the hunters, anticipating the success of their purveyor's assiduity, are prepared to slaughter the poor birds, either singly, by means of a kind of spear, or in dozens, by discharging among them a volley of large shot from a blunderbuss, or other gun of large calibre. This comprehensive execution by the gun will not, it seems, succeed oftener than once in a season, as the noise makes such an impression on the ducks, that they remember the effects, and ever after avoid a similar decoy. (f)

BÆTOEN, a serpent described by Forskal in his *Fauna Arabica*, whose bite proves almost instantaneously mortal, and produces an universal swelling of the whole body. The characters of this formidable animal are not sufficiently marked to fix its place in a systematic arrangement, little more being known of it, than that it is freckled with black and white spots. (f)

BÆCKIA, a genus of plants of the class Octandria, and order Monogynia. See **BOTANY**. (w)

BÆBOTRYS, a genus of plants of the class Pentandria, and order Monogynia. See **BOTANY**. (w)

BÆTICA, the name of one of the ancient provinces of Spain, comprehending modern Andalusia and Grenada, taken from the river Bætis, now the Gaudalquivir. (j)

BAFFIN'S BAY, a large bay lying between North America and Greenland, which derives its name from

William Baffin, who endeavoured, in 1616, to discover a passage through Davis's Straits. Its limits have not yet been ascertained by any accurate observations. See Crantz's *History of Greenland*. (j)

BAGAUDÆ, the name of a band of turbulent peasants, who frequently disturbed the tranquillity of the Roman empire. See Crevier's *History of the Roman Empire*, vol. ix. p. 282. (j)

BAGDAD, a city of Turkey in Asia, and capital of the Pachalek of Bagdad, and of the Babylonian or Arabian Irac, is situated on the banks of the river Tigris, in N. Lat. $33^{\circ} 22'$, E. Long. $44^{\circ} 21'$, and was founded by the Caliph Abu Jaafar Almansor, in the 145th year of the Hegira, A. D. 762. It has been very erroneously supposed to occupy the same spot on which ancient Babylon formerly stood; and the mistake may have originated, from the circumstance of its being built upon the site of Seleucia, which was frequently styled New Babylon; but the old city of that name stood upon the banks of the Euphrates, about 50 miles farther up the river. Bagdad is indeed the last of a succession of magnificent cities, which were built at different periods in the same extensive plain, and each of which was raised from the ruins of its predecessor. Babylon was exhausted of its inhabitants and its ornaments by the city Seleucea; Seleucea, again, was supplanted by Ctesiphon; which, in its turn, yielded to Almadayen; and, last of all, Bagdad supplied a residence to the sovereigns of the East.

Almansor, the second Caliph of the family of the Abassides, having disgusted, by his cruelties, the inhabitants of Hasomia, where he usually resided, and having thus given occasion to insurrections against his government, as well as conspiracies against his life, he resolved to abandon a place, which was so determined in its disaffection, and to remove the seat of the empire to a city founded by himself. The following account is given by the Persian writers of the foundation of the new city, and the origin of its name. Khosru, named Amishirwan, had given the plain on which it stands to one of his wives, who built and dedicated there a chapel or oratory to her favourite idol Bagh; and from this circumstance the whole of the neighbouring district was called Baghdad, *i. e.* in the Persian language, "the gift of Bagh." This little temple, in process of time, served as a place of retreat to a hermit of extraordinary sanctity, who happened to meet with Almansor, while he was riding on the banks of the Tigris, and meditating on his new scheme; and who, upon learning from one of the attendants the design of the caliph, mentioned an ancient tradition, that a city was to be built in that place by a person named Moclas. Almansor, having been informed of the hermit's observation, declared to his officers, that the name of Moclas had been given to him by his nurse; gave thanks to God for having destined him to be the author of so great a work; and instantly fixed upon the spot where he stood as the situation of his intended capital.

According to the Arabian authors, however, there was none of these marvellous and romantic occurrences in the caliph's proceedings. The ground was deliberately chosen near the confluence of the Euphrates and the Tigris, as being a favourable situation, both for the defence of the city, and for the conveyance of provisions; and it was called Baghdad, *i. e.* the garden of Dad, because a Christian monk, of the name of Dad, had been residing on the spot where it was built.

The first part of the city was situated on the western bank of the Tigris; and was of a circular form, with the caliph's palace and the great mosque in the centre. While the buildings on the eastern side were erecting, Almansor detached a body of troops, under his son Al Mohdi, to protect the workmen from the attacks of the Persians; and the young prince having fortified, with a wall, the place on which he encamped, that part of the city was afterwards called "the Camp or Fortress of Al Mohdi." The caliph had a palace in the eastern as well as in the western division of the city, both of which had the appellation of "the House of the Caliph;" but that on the eastern bank was the most magnificent, and was called, by way of eminence, "the Garrison," or "the Royal Inclosure." It was surrounded, on the land side, by a semicircular wall, with six gates, the chief of which was called "the Gate of the Præfects;" and its entrance was generally kissed by the princes or ambassadors, who came to the court of the caliph. The city was completed in the 149th year of the Hegira, A. D. 766; and received the name of Medinat al Salam, "the city of peace," alluding either to the name of Jerusalem, or to the quiet which prevailed throughout the empire at the time when it was finished, or to the name which was frequently applied by the Orientals to the river Tigris, viz. Vadi Assalam, "the torrent of peace." But whatever was the reason of this appellation, it was generally adopted by the neighbouring nations; and hence the city of Bagdad is often called by the Greeks, Irenopolis, which is equivalent to the Arabic, Medinat al Salam. The city, when completed, was of a circular form, inclosed with a double wall, and defended by a considerable number of towers. Its gates were disposed in such a manner, that those of the first wall were in a sloping or oblique direction with respect to those of the second; and from this circumstance, it was sometimes called by the Arabians, Zaura, *i. e.* "the crooked." In the centre of the whole was the castle, or citadel, which commanded every part of the town; and a bridge was constructed over the Tigris, to facilitate the communication between the two divisions of the city. Bagdad was much enlarged and beautified by succeeding caliphs; but particularly by Mostanser Billa, who founded there the famous college, which the Arabs called Al Madrasah Al Mostanseriah; and which was remarkable for the elegance of its structure, the greatness of its revenues, and the number of its students. It contained also several other well endowed colleges; was renowned for the elegance of the Arabic spoken within its walls; and produced a greater number of learned men, than any other place in the Mahomedan dominions, except Mecca and Medina.

The city of Bagdad continued to be the seat of the caliphs of the house of Abbas, and the capital of the Moslem empire, for the space of more than 500 years. During this long period it sustained several obstinate sieges, and was the scene of many a bloody revolution. In the 197th year of the Hegira, A. D. 812, it was attacked by Al Mamon, the second son of Haroun Al Raschid, who had rebelled against his elder brother Al Amin; and by a siege of twelve months, almost the whole eastern part of the city was laid in ruins. In the 341th of the Hegira, A. D. 945, it was afflicted by so severe a famine, that many persons were punished for feeding upon the flesh of children; and this dreadful calamity was followed by pestilence, which swept away

great numbers of the inhabitants. In the 417th of the Hegira, A. D. 1026, it was besieged by a numerous army of Turks, who plundered, and set it on fire; by which means the best part of the city was consumed, and the inhabitants reduced to a state of extreme poverty. In the 447th of the Hegira, A. D. 1055, it was pillaged by the troops of Trogrud, or Trogrul Beck, who assumed to himself the office of Emir-al-omra, and made great encroachments upon the power of the caliphs. At length, in the 656th of the Hegira, A. D. 1258, Bagdad was taken by Hulaku, or Hulagou, the grandson of Zengis, the Mogul, or Tartar; its reigning prince, Al Mostasom Billah, put to death; the caliphate itself abolished; and the city given up to pillage and massacre for the space of seven days. It remained in the possession of the Tartars or Moguls till the year of the Hegira 796, A. D. 1393, when it was taken by Timur Beg, or Tamerlane the Great, from Sultan Ahmed Ebn Weis, who abandoned his capital to the conqueror, and took refuge in the territories of the Greek Emperor; but who found means to regain the city in a short time, and to keep possession till the 803d of the Hegira, A. D. 1400. It was then attacked a second time by Timur, and vigorously defended by Ahmed's governor Farruj. At the end of forty days, however, it was taken by assault, the inhabitants barbarously massacred, and the principal building levelled with the ground. From this period, it was alternately in the hands of Sultan Ahmed, of Abubekr, grandson of Tamerlane, and of Kara Yusef the Turkoman, till the year of the Hegira 815th, A. D. 1412, when it was completely secured by the last mentioned prince, and remained in the possession of his descendants, till the year of the Hegira 875th, A. D. 1470. It was then occupied by Usun Cassan, in whose family it continued till the 916th of the Hegira, A. D. 1510, when it was taken by Shah Ismael, surnamed Sofi; and, for 120 years after, it was the object of perpetual contest between the Turks and Persians. In the year of the Hegira 1048th, A. D. 1658, it was besieged by Amurath, or Morad IV. and though the Persian garrison, after a brave resistance, had procured an honourable capitulation, they were treacherously massacred, and the town given up to pillage by the cruel conqueror.

From this period Bagdad has greatly declined in extent and magnificence; but is still a place of great consequence, of considerable trade, and of more wealth than any other city in the world of the same size. It is the resort of great numbers of traders and travellers, who pass into Persia from Natolia, Syria, Palestine, and Egypt. It is visited from a principle of religion, by multitudes of devout Mussulmen, who imagine that Ali once resided in the city. All the pilgrims also who go to Mecca by land, must pass through Bagdad, and pay to the Basha a kind of tax or toll, of four piastres. The professed religion is the Mahomedan; but the greater part of the people are called Rahedis, a sect of heretics, who are peculiarly strict in separating themselves from persons of a different religious persuasion, and who would not drink out of the same cup with a Christian, or a Jew, and scarcely even with an orthodox Mahomedan. Various sects of Christians, however, are tolerated in the city, of which the Nestorians are the most numerous. There are several Jews, who are confined to a remote quarter of the town. They are hated and continually insulted by the Turks, and live here, as in most other places, in a state of political degrada-

ion and oppression. Many also repair hither annually to visit the sepulchre of the prophet Ezekiel, which they suppose to be in the neighbourhood of the city.

The inhabitants of Bagdad are composed of Persians, Armenians, Turks, Arabs, and Jews; but their number has been estimated very variously at different times by different travellers. By Tavernier, in 1652, they were supposed not to exceed 15,000; and by an officer of the East India Company, in 1779, they were computed at 100,000. They are not, however, the vile slaves we imagine them, and which we consider as the invariable consequence of a despotic government; but are, on the contrary, proud, enterprising, active, and inclined to mutiny. The higher classes are civil and generous, and obliging to strangers, whom they always treat with regard and distinction. It is true the lower classes are the same as in all the other cities of Turkey, ignorant, rude, full of superstition and insolence, and enervated by debauchery and idleness.

The form and fortifications of the city seem to have undergone little alteration; and the different descriptions which have been given of its appearance during the last 150 years are very much the same. It looks, at a distance, like a grove of trees; and stands in the midst of a very fertile soil, which is left almost entirely destitute of cultivation, but which nevertheless produces all the European fruits and vegetables in their proper seasons, and in the greatest perfection. The city is in the form of an irregular oblong square, about 1500 paces long, 800 broad, and not above three miles in circuit. The walls are built with brick, terraced in several places on the top, strengthened with large towers like bastions, mounted with 60 pieces of cannon, of which the largest are five or six pounders, and surrounded by a wide ditch, about five or six fathoms in depth; but these fortifications are very much broken down in several places, and the ordnance in such a decayed state, as to be scarcely fit for service. There are four gates, one of which is on the side of the river; and the entrance to the city in that quarter is by a bridge of boats, or rather pieces of timber fastened upon goat skins, which are blown like bladders. Near to one of these gates, on the north side, stands the castle or citadel, which has the command of the river, and which is planted with a number of cannon, but is not capable of very much resistance. Some of the public buildings, the mosques, minarets, hammams, and the palace of the bashaw's lady, are built of hewn stone, and make a handsome appearance; but there are neither public schools, nor public libraries. The bazars, or markets, are very extensive, protected by arches from the excessive heat of the sun, divided into different streets, and filled with shops to the number of 1200, in which all kinds of merchandize are to be found. There are also to be seen the remains of several ancient edifices, of lofty structure and beautiful workmanship; especially a large khan, supposed to have been built about 850 years ago, and of which the bricks appear as fresh as if they had been newly made. "The houses," says a late traveller, "are generally large, built of brick and cement, and arched over; many of the windows are made of elegant Venetian glass; the ceilings are mostly ornamented with a kind of chequered work, which has generally a noble appearance; most of the houses have a courtyard before them, in the middle of which is a little plantation of orange trees, &c. that has a very pleasing effect." *Journey from Bassora to Bagdad in 1779*, p. 46.)

In the months of June, July, and August, (we are informed by the same traveller, as well as by Tavernier,) the weather is so extremely hot, that the inhabitants are obliged to live in subterraneous apartments, or at least to sleep upon the terrasses of their houses. The Samiel rages here from the beginning of July to the middle of August, but is neither of such a pestilential quality, nor followed by those fatal accidents which often attend it in the desert. (See ARABIA, vol. ii. p. 275.) The women of Bagdad are very richly habited; and are loaded with jewels and rings, both at their ears and nose. Except they be very poor, they never go out but on horseback; and on these occasions, it is said, the courtezans are distinguished by putting their feet into the stirrups, while others use only the leathers.

The city is governed by a Pacha of three tails, who assumes also the title of caliph, from his capital having been the ancient residence of the Arabian pontiffs. He exercises an authority almost entirely independent of the Porte, and is looked upon as the most powerful vizier in the Ottoman empire. The present governor *Ali*, is a native of Georgia, who, from being the slave of Soliman Pacha, became his son-in-law, and successor; and it is worthy of remark, that for nearly a century past, almost all the Pachas of Bagdad have been Georgian renegados, whom intrigues and good fortune have drawn from the horrors of slavery, to conduct them to the honours of unlimited power. In the time of Tavernier, the forces of Bagdad consisted of about 2000 troops of different descriptions, within the walls; and about 3000 or 4000 cavalry in the suburbs and neighbouring towns. But, at present, these can be increased to more than 30,000, as many cavalry as infantry. The cavalry, particularly those of Kurdistan, are armed with a pistol, a lance, and a sabre, and sometimes also with a carbine. The Arab horsemen, however, use only the lance; and the infantry carry a sabre and musket. *Ali* Pacha has, besides, 500 foot disciplined after the European fashion; and he can carry into the field 30 pieces of cannon, served by skillful soldiers. His army, however, is wretchedly paid, and ill treated, so that it is composed chiefly of the refuse of the populace. The civil government is executed by a *cadi*, who acts in all capacities, and discharges at once the offices of judge, *mufti*, and *tofterdar*, or treasurer for the grand signior.

The revenues, which are drawn chiefly from the customs, the annual contributions of governors and intendants of cities, and the tribute of the Arab tribes, which are dependant upon the government of Bagdad, may be computed at seven millions and a half of piastres, or 337,500*l.* sterling. This would be considerably increased, were not the Kurdes (inhabitants of Kurdistan) exempted from all fixed contributions, on account of their eminent services in the field, and the frequent campaigns they are obliged to make; and were not the products of the city of Bassora so impoverished by the ruin of its commerce, that they are scarcely adequate to defray the expense which it demands for its defence. But even this sum is seldom fully collected, on account of the slothfulness of the Turks, who often suffer themselves to be plundered by the Arabs.

In the reign of Soliman Pacha, Bagdad was the centre of a rich and extensive commerce; but many obstacles have since arisen, which have paralysed the exertions, and almost destroyed the activity of its merchants. The dangerous navigation of the Mediterranean, occasioned by the war between Britain and France; the

intestine disorders of Persia; the monopoly of Indian produce by the English; the frequent excursions and robberies of the Wahabees; the continual discord which reigns in Turkey, and the unprotected state of agriculture and industry in that empire; are the principal causes which have led to the present derangement of the commercial affairs of this city. Notwithstanding, however, these obstructions, and the comparative inferiority of Bagdad to its former opulence as a place of trade, it may still be considered as the great emporium of the East. The productions of Arabia, India, and Persia, are landed at Bassora, from which they are carried in large boats, that ascend the Tigris or Euphrates to Bagdad, where they find a ready market, and from thence are spread over the other cities of Turkey. Europe furnishes it with merchandize of every description, as also with the productions of America. Muslins, rich silks, and cotton stuffs, are brought from Coromandel; indigo from Bengal; shawls and aromatics from Cashmere; sugar from Java; cloves from the Moluccas; and pepper from the coast of Malabar. In return for these it has nothing of its own to offer; and, except dates, tobacco, and a small quantity of woollen stuffs, which are its only exports, the trade of Bagdad consists entirely in the distribution and exchange of foreign commodities. According to a late traveller, "the commerce of this city suffers also greatly from the oppression and cruelty of the Pachas, who are continually extorting money from the poor inhabitants; and none suffer more than the unfortunate Jews and Christians, many of whom are put to the most cruel tortures, in order to force their property from them. This series of tyranny has almost entirely driven them out of the city, in consequence of which the trade must suffer considerably, they being generally the principal merchants in the place. Were the city mildly governed, it is so well situated for traffic, that it certainly would be the residence of a number of Christian merchants, which would make it one of the richest and most flourishing places in the world." *Journal of a Journey from Bassora to Bagdad*, in 1779. BAGLAFECHE, in Zoology, a variety of the *Loxia Philippiana*, or Philippine grosbeak, found in Abyssinia, and distinguished from this latter bird by having the tail and quill feathers of a greenish brown, edged with yellow. The *baglafecht*, like another species of this tribe, (See ORNITHOLOGY,) displays admirable care and instinctive foresight in the construction and position of its nest, which it builds of a spiral form, somewhat like the shell of the *nautilus*, with the entrance below, and suspends at the very extremity of a slender twig, so as to turn with the gentlest breeze, and be out of the reach of predacious animals. See Buffon, *Histoire Naturelle des Oiseaux*; and *Dictionnaire des Sciences Naturelles*, tom. iii. (f)

BAGLANA, or **BAGLANEH**, a mountainous but fertile province of the Mogul empire, defended by no fewer than nine strong fortresses, built on the summits of lofty rocks. It was long an independent province, and its

revenue before the Mogul conquest was 80,000*l.* See Rennel's *Memoir*, p. 259. (π)

BAGPIPE, the *ασκαυλος* of the Greeks, and the *Tibia utricularis* of the Romans, is a well known musical instrument, which has erroneously been supposed peculiar to Scotland and Ireland. The ancients, both Greeks and Romans, however, were acquainted with it; and in many countries it is a favourite and popular instrument at this day.

The bagpipe, as constructed at the present period, consists of a large leather bag, inflated by the mouth, or by means of bellows. Connected to it is a flute part, or chaunter, as it is called, into which is inserted a reed, and the action of the air from the bag on this reed produces the music. The chaunter is perforated with holes like a common flute, for the different notes. The other parts are three drones, also consisting of reeds and tubes, two of which are in unison with D, on the chaunter, or the first note of the German flute, and the third, or long drone, is an octave lower.

The bagpipe is an extremely defective and imperfect instrument in all its different kinds, of which there are four. First, The Irish or soft pipe, in which the chaunter takes a range of ten or twelve notes with tolerable precision, and which is always played with bellows: the reeds are softer, and the tubes longer, whence the Irish pipe is more suitable for performance in an apartment. An improvement has been attempted, by adapting three or four keys like flute keys on one of the drones; by pressing one of these with the arm, a third or fifth to the note of the chaunter is produced, which forms an intermediate chord with the drone, and has a pleasing effect. The second kind of this instrument is the Scottish or Highland bagpipe, which is played either with the mouth or with bellows, like the Irish pipe; and excepting that, as far as we know, keys have never been adapted to it, is almost the same in every respect. The principal difference consists in the reeds being constructed to produce a louder sound, and the drones are shorter. Third, The small, or Northumbrian bagpipe, which is the Scottish bagpipe in miniature. Properly speaking, the Scottish bagpipe has but eight or nine good notes: one or two more may be gained by what pipers technically call pinching, that is, half covering the thumb hole, which sometimes is attended with the most disagreeable tones. Nothing is so well adapted for the bagpipe as tunes consisting of few notes, and all set on the same key; for its compass is really very limited, and by no means of that extent of which most performers endeavour to persuade themselves. From the limited compass of the instrument, and its imperfections, we find but little music written for it; to which may be added another reason, that those in general who can play cannot write. The favourite and peculiar music is the Highland Pibrach, which we confess has always appeared to us utterly unintelligible. It is supposed to be a battle piece, a march, a lamentation, or the like; and sometimes occupies a complete half hour or more in performance.

Of the progressive history and improvement of the bagpipe to its present state, we know very little. It is supposed that there are allusions to an instrument of similar construction in sacred writ; and there is no doubt that it is the origin of the organ. Perhaps it first consisted of an inflated bag alone, with the pipe and reed; and in such a form it seems to have been used by

the Greeks, and also at a later period by less civilized nations. By the Romans it was called *tibia utricularia*, and, as certain authors have conceived, *chorus*, or *choraulus*, and it was probably played in the same way as the modern Highlanders play it.

Et cum multifori tonius cui tibia buxo
Tandem post epulas et pocula multicolorem
Ventriculum sumpsit, buccasque inflare rubentes
Incipiens oculos aperit, cilisque levatis
Multotiesque alto fature pulmonibus hausto
Utrem implet, cubito vocem dat tibia presso
Nunc huc nunc illuc digito saliente.

VIRGIL.

Suctonius speaks of the bagpipe; and it appears that Nero, the Roman emperor, played on it. On one of his coins a bagpipe appears, and we are told of a piece of sculpture, not long ago in Rome, of this instrument, greatly resembling its present form. The sculpture was supposed Grecian. St Jerome, in his epistle to Dardanus, alludes to the bagpipe in its more simple shape: *antiquis temporibus fuit chorus quoque simplex fellis cum duabus cicutis areis, et per primam inspiratum secunda vocem emittit*. In France it appears likewise in its simple state, in the *Danse des Aveugles*, in the 15th century; and it is among the instruments represented in the Dance of Death, at Basle, in Switzerland.

The bagpipe is said to be of great antiquity in Ireland, and to have been early known in Britain. In the twelfth, or thirteenth century, we see it represented without drones, or with only one, having a flag, bearing a coat-armorial, such as was recently used in the Highlands of Scotland. King Edward III. had pipers; and Chaucer, speaking of the minstrels, a vagrant tribe, describes the bagpipe under the name of *cornmusc*, which is the appellation at present given to it in France:

Cornmusc and shalmes, many a floyte and lytlynge horn.

Among the musicians of Queen Elizabeth's household are named pipers.

With regard to the introduction of the bagpipe into Scotland, we are altogether uncertain. Eminent authors have affirmed, that it was not known at the battle of Bannockburn, in 1314. But a bagpipe, with one drone, appears among the sculptures on Melrose Abbey, which, we are told, is a very old edifice. James I. of Scotland, who was murdered in 1436, is said to have been a performer on this instrument. We only know of its being in general use during the last, or perhaps the preceding century. At present it enters the list of military instruments, for every Highland regiment has a piper; and, as a national instrument, we have heard of institutions for teaching it in the isles of Mull and Skye. Neither pupil nor preceptor, however, being able to read, musical notes were represented by pins driven into the ground. To encourage the cultivation of this instrument, annual premiums have been recently distributed by the Highland Society to the most eminent performers. A competition, generally in the end of July, takes place before a committee of that Society at Edinburgh, who decide on the merits of the candidates. The competition lasts several hours; and Highland dances, introduced by way of interlude, are performed with uncommon skill and agility. We doubt if this kind of music can ever be brought to great perfection, on account of the defects inseparable from the instrument. But the

passionate attachment which the Highlanders display for it, and the use of which it has actually been in gaining victories on the day of battle, render it a fit subject for encouragement. See Bartholinus *De Tibiis Veterum*. Montfaucon *Antiquit. explic. Essai sur la Musique*, tom. i. Fordun *Scotichronicon*. Pennant's *Tour in Scotland*, vol. i. ii. Kotzebue's *Travels in Italy*. Strutt's *Sports and Pastimes of the People of England*. (c)

BAHAMA ISLANDS, a name given by the English to that cluster of small islands, rocks, and reefs, called by the Spaniards *Lucayos*, which stretch, in a north-westerly direction, from the northern coast of Hispaniola to the Bahama strait, opposite the Florida shore; a space of near 300 leagues, from about 22° to 25° of N. Lat. and from about 70° to 80° of W. Long. The whole number of these islands, comprehending those, whose smallness, barren soil, or want of water, render them uninhabitable, amounts to about 500. Of these, the principal are—Providence, 27 miles long, and 11 broad, whose capital, Nassau, is the seat of government; Abaco, Harbour Island, Eluthera, Exuma, St Salvadore, called by the Indians Guanahani, Long Island, Andros, and Bimini. These islands, though unimportant in themselves, and but little known to European geographers, are entitled to particular notice, as it was on one of them that the great Columbus first landed, after a voyage, the most adventurous and magnificent in design, and the most important in its consequences to the two hemispheres, that had ever been undertaken. The island which was thus honoured was St Salvadore, to which English mariners have given the name of Call Island. Here Columbus erected a cross; and, taking possession of it in the name of his Catholic majesty, gave it the appellation which it still bears. The more important and inviting regions, however, which he afterwards discovered, prevented him from making any permanent settlements in St Salvadore; and the Bahamas were completely neglected, till, about the year 1629, the English, then animated with all the ardour of adventure, began to plant on the island of Providence, which had hitherto been uninhabited. Some years after, captain Sayle, an English mariner, then on a voyage to Carolina, was forced, by stress of weather, to land on one of these isles; and, on his return to England, made so favourable a report of their soil and climate, that a grant of them was solicited and obtained by six of the proprietaries of Carolina. Sayle soon after visited them a second time, and gave the English government such a flattering account of the advantage which might be derived from the possession of the island of Providence in particular, that they were induced to send out thither a governor and colony, about the year 1672. This settlement, however, was so much harassed by Spanish pirates, that it became necessary to abandon Providence, and all the Bahama islands. They now became the resort of pirates, who annoyed the American trade to such a degree, that the English government was at length compelled to take some strong measure in order to reduce them. In the year 1721, King George I. on the conclusion of peace with Spain, sent out a force to dislodge these outlaws, and to fortify and settle the island of Providence. The Bahamas, however, have never risen to any degree of importance among the other islands in this immense commercial archipelago. Such, indeed, was their insignificance, that scarcely any information could be obtained concerning them, even by the lords of the committee of council for the affairs of trade and plantations. "To

the inquiries of their lordships, in 1789," says Mr Bryan Edwards, "as to the extent of territory in these islands, the quantity of land in cultivation, the number of white inhabitants, productions, exports, &c. the only answer that could be obtained from the governor, was, that it was at that time impossible to ascertain any of those particulars. It appears, however, from the testimony of other persons, that these islands are in general rocky and barren; that the only article cultivated for exportation is cotton, of which the medium export is 1500 bags, of 2 cwt. each; that the inhabitants (who, in 1773, consisted of 2652 whites, and 2241 blacks) have of late years been considerably augmented by emigrants from North America; but of their present numbers no precise account is given." See Edward's *History of the West Indies*, vol. i. p. 574, 8vo edit. (x)

BAHAR, the name of one of the eleven provinces into which Hindostan was divided by Acbar. It is situated to the west of Bengal, and is about 250 miles long, and 200 broad. Wheat, rice, and pease, are produced in considerable quantities, and the province furnishes the greater part of the saltpetre which is imported by the East India company, and a considerable proportion of the cotton sent to England to be printed. The chief produce of this province is opium, which is now become a most important article of commerce, from the great demand for this drug in China, into which it is smuggled with the connivance of the government. The revenue of Bahar under Aureng-zebe was 101½ lacks of rupees. Patna is the capital of the province, the greater part of which belongs to the British. See Fraser's *History of Nadir Shah*, p. 34.; Hodge's *Travels in India*, p. 44.; and Valentia's *Travels*, vol. i. p. 91. (o)

BAHIA DE TODOS LOS SANTOS, or SAN SALVADOR, the name of the chief town of a rich province of the same name in Brazil. It is situated on the eastern side of All Saints' Bay, on a rocky foundation, often 600 feet above the level of the sea, and is defended by a numerous garrison, and by several forts and batteries. The revenue of the city is partly derived from exorbitant duties on merchandize, but chiefly from the Brazil wood and from the produce of the gold and diamond mines in the neighbourhood. The trade of Bahia with Lisbon and Oporto is carried on by means of about 50 vessels, which supply the province with linen, woollen, silks, hats, wheat, flour, rice, wine, furniture, bacalhao, cheese, salt, and the manufactures of Europe and India; and carry back gold, cotton, sugar, coffee, tobacco, skins, and a variety of woods, balsams, and gums. The province of Bahia extends about 50 leagues along the coast. Provisions are very dear, and the climate unhealthy. The population of the city is nearly 100,000; of which 30,000 are whites, 30,000 people of colour, and 40,000 negroes. E. Long. 59°, N. Lat. 12° 30'. See Lindley's *Narrative*, 8vo. 1805, p. 271.; and sir G. Staunton's *Embassy to China*, vol. i. See also BRAZIL and ST SALVADOR. (o)

BAHR EL ABIAD. }
BAHR EL AZREK. } See ABYSSINIA.

BAHRIN, or BAHREIN, or BAHAREM, a word signifying *two seas*, is the name of a group of small islands situated on the western side of the Persian gulf, and long famous for their pearl fishery. The chief islands are Aval or Bahrin, Samahe, and Arad, or Ennebi Sa-behh. The Bahrin islands once belonged to the Portuguese, but afterwards fell into the hands of the Per-

sians and Arabians, who obtained alternate possession of them. They now belong to the Schiek of Busheer; but the revenue which he derives from them has been much diminished by the obstinacy of the Houls, a tribe of Arabs between Gombroon and Cape Bardistan, who refuse to pay duty for the privilege of fishing pearls. The unequal pearls are sent to Constantinople, and other parts of Turkey, and the perfect ones are exported to Surat, from which they are diffused over the whole of Hindostan. The fishing vessels, amounting according to some to 3000, and only to 300 according to others, pay several duties, one to the king of Persia, another to the sultan of Bahrin, and a third to the prince to whom the fishermen are subject. The pearls found here sometimes weigh 50 grains, but in general their weight is only about 10 or 12 grains. The inhabitants of Bahrin obtain from Surat their cloths and silks, by means of Moorish merchants. A lack of rupees, the annual amount of the Schiek's revenue, is scarcely sufficient to support the fortifications of Bahrin, and maintain the garrison. We are informed by Niebuhr, that at some distance from these islands, at the depth of 2½ fathoms, the fishermen have found good spring water, and are in the habit of diving to the bottom to fill their bottles. The whole group of islands contain about forty or fifty mean villages. The inhabitants are Shiutes, and speak the Arabic language. E. Long. 48° 10', N. Lat. 26° 40'. See Niebuhr's *Travels*, sect. xxiii. chap. vi. and Peuchet's *Dict. de Geograph. Commerç.* See also AVAL. (j)

BAIÆ, or BAIAS, now BAIA, an ancient village of Campania, now the province of Lavora in Italy, celebrated for its hot baths, and for the mild temperature of its climate. Owing to the vast demand for buildings, and to the smallness of the place on which they could be erected, the sea was driven back by huge moles and buttresses, and Baia became a large and opulent city, and flourished till the time of Theodoric. After the irruption of the northern hordes, however, Baia declined in wealth and splendour. The sea broke down the barriers which confined it, and frequent earthquakes completed the devastation of this enchanting retreat. See Martial, xiv. ep. 81; Horace, i. ep. 1; Strabo, lib. v.; Keyser's *Travels*, vol. iii. p. 144, 145; Kotzebue's *Travels in Italy*, and Swinburne's *Travels*, vol. iii. p. 42. (o)

BAIANUS SINUS. See Swinburne's *Travels*, vol. iii. p. 48, and Pozzuolo.

BAJAZET I., sultan of the Turks, and a celebrated warrior, was the son of Amurath I., whom he succeeded in the throne of Bursa, in the year 1389. He was 44 years of age when he assumed the government, and, during a period of 14 years, he ravaged alternately, with savage fury and enthusiasm, the continents of Asia and Europe. Bred in the camp of his father, his youth was spent in the exercise of arms. He had shared the dangers, and he inherited the warlike spirit, of the victorious Amurath; but the mildness and modest demeanor of the father, was lost in the haughtiness and cruelty of the son. The first act of his reign was marked with the blood of his brother, whom he accused of aspiring to the throne; and Lazarus, prince of the Servians, was beheaded in his presence, to expiate the guilt of his countrymen, who were charged with the death of Amurath. The love of conquest was Bajazet's ruling passion, and Christian and Moslem equally felt the effects of his ambition. After having overrun Caramania, and

the northern regions of Anatolia, he crossed the Hellespont, and reduced to subjection the Bulgarians and Serbians. Passing the Danube, he overthrew Stephen, prince of Moldavia, on the banks of the Siret; but the triumphant Othman was checked in the career of victory by a handful of Moldavians. Stephen, animated by despair, having collected 12,000 of his countrymen, returns to the field of battle, disperses the enemy scattered abroad in quest of plunder, and afterwards defeats them with dreadful slaughter near his capital Jassi. The sultan of Bursa, the terror of the world, is compelled to fly with a few attendants to Adrianople; and seven huge piles of Turkish bodies proclaim the valour of Stephen, and the disgrace of Bajazet. Disturbances in Caramania demanded his immediate presence in Asia; and the haughty Othman, more enraged than discouraged by his late disasters, hastily raises an army in Europe, and, by the incredible rapidity of his march, falls upon the astonished Caramanians, while they believed that he was still on the north of the Hellespont.

The Grecian empire was confined by Bajazet within the walls of Constantinople, which was suffering all the horrors of a blockade. The princes of Christendom, moved by the suffering situation of their brethren, determined to crush at once the presumptuous Moslem, who had threatened to annihilate the power of the emperor of the East. Sigismund, king of Hungary, commanded the bravest knights of Germany and France, who were eager to try their prowess against the "usurping infidel;" and 100,000 warriors boasted, that if the sky should fall, they could uphold it on the points of their lances. Bajazet met them at Nicopolis. The Christians were routed. The greatest number were either slain or drowned in the Danube, and Sigismund escaped only with his life. A train of noble captives graced the triumph of the Othman sultan; and 200,000 ducats redeemed the count of Nevers, and twenty-four lords of France. It was stipulated, that they should never carry arms against the person of their conqueror; but the pride of Bajazet relieved them from the ungenerous restraint: "I despise," said he to Nevers, "thy oaths and thy arms. Thou art young, and mayest be ambitious of effacing the disgrace or misfortune of thy first chivalry. Assemble thy powers, proclaim thy design, and be assured that Bajazet will rejoice to meet thee a second time in a field of battle." Bajazet now returned to the destruction of Constantinople. His haughty mandate was delivered to the emperor: "Thou hast nothing left beyond the walls of your capital. Resign that city, and stipulate thy reward, or tremble for thyself and thy unhappy people." But this city was preserved by the appearance of an enemy equally hostile to the Christian powers. Tamerlane the Great had entered Armenia with a mighty army, and demanded of Bajazet submission and obedience. The epistle of the Tartar breathed defiance and contempt, and concluded with these insulting words: "Thou art no more than a pismire; why wilt thou seek to provoke the elephants? Alas! they will trample thee under their feet." Bajazet had been accustomed to the language of adulation and dependence, and could ill brook the scoffs of an equal. The feelings of his indignant soul burst forth in the keenest reproaches. He branded Tamerlane as the thief and rebel of the desert, who had triumphed only by his perfidy. He dared him to try the arrows of his flying Tartars against the scymitars and battle-axes of his invincible Janizaries: "The cities of Arzingan and

Erzeroum are mine," said he, "and unless the tribute be duly paid, I will demand the arrears under the walls of Tauris and Sultania." The armies of the rival chiefs encountered on the plains of Angora. Bajazet displayed all the qualities of a soldier and a general, but he could not prevent the flight and desertion of his troops, some of whom had been tempted by the promises of Tamerlane. After a most obstinate and sanguinary conflict, in which 340,000 combatants are said to have fallen, the Turks were defeated, and Bajazet was taken in the pursuit.

The conduct of Tamerlane towards his captive rival has been variously described. The "iron cage," in which Bajazet was confined, and against the bars of which he is said to have dashed out his brains in vexation and despair, has been rejected by some as a popular tale. But though the Persian historians are altogether silent upon this subject, we see no sufficient reason for discrediting the testimony of Poggius, Phranza, and their contemporaries, who assert, with confidence, the imprisonment and harsh treatment of Bajazet. We confess, however, that we cannot enter into all the circumstances of the story; but allowing for the exaggeration of some, and the inaccuracy of others, a fair and warrantable conclusion may be deduced, that Bajazet owed his premature death to the severity of Tamerlane. Taking even the relation of Tamerlane's panegyrist as an authentic record, the generosity of the Tartar towards his captive was at best but a mockery. It was the generosity of a barbarian, who sacrificed nothing to his humanity, and who wished to attract the applause of his followers by his condescension. At a splendid banquet, amidst a crowd of dependants, he invested Bajazet with the ensigns of royalty, bestowed upon him the kingdom of Anatolia, and promised to restore him to the throne of his fathers; but he still kept him in confinement, and exposed him as a trophy of his valour and good fortune. Bajazet died of an apoplexy at Akshehr, about nine months after his defeat, A. D. 1403. Tamerlane dropt a tear over his expiring victim; reflecting upon the instability of fortune, which, by the chance of war, might have rendered the fate of Bajazet his own. His corpse was conveyed with royal magnificence to Bursa, and there interred in his own mausoleum.

The ambition of Bajazet kept him almost continually in the field. After the battle of Nicopolis, he proudly threatened to lay siege to the capital of Hungary, to subdue the adjacent countries of Germany and Italy, and to plant the crescent on the capital of the Romish Hierarchy. The fiery energy of his soul, the secrecy with which he concealed his designs, and the rapidity of his march, procured him the appellation of "Ilderim," or lightning; and in the pride of conquest he compared the march of the Tartars to the creeping of a snail. His justice was that of a despot, who disdains to balance the weight of evidence, or to measure the degrees of guilt. He ordered the belly of one of his chamberlains to be cut open for drinking the goats-milk of a poor woman; and his clemency was an act of condescension rather than of humanity. In the midst of war, he forgot not the arts of peace. He was a great lover of architecture; and temples, academies, and hospitals, were erected by him every year. He was the first Othman sovereign who assumed the title of Sultan, his predecessors having contented themselves with that of Emir; and a fleet of galleys, stationed at Gallipoli to

guard the passage of the Hellespont, were built at his command, and was the first navy ever possessed by the Othmans. See *Mod. Un. Hist.* vol. xii. p. 68—89. *Memoires de Boucicault.* D'Herbelot, *Biblioth. Orientale.* Gibbon's *Hist.* chap. 64, 65, 4to, vol. vi. p. 321—357. (f)

BAIDARS, the name of a kind of canoe used by the natives of the Kurilly Islands, and of the north-west coast of America. See Sauer's *Account of Billing's Expedition to the Northern Parts of Russia from 1785 to 1794*; and Sarytschew's *Account of the Voyage of Discovery to the N. E. of Siberia*, chap. vii. (j)

BAIKAL, a lake situated in the government of Irkutsk in Siberia, and, next to the Caspian Sea, the largest expanse of water within the limits of the Russian empire.

Nowhere perhaps, could a person, who should traverse the globe, meet with an object more truly interesting than the Baikal, whether we consider the rude sublimity of its scenery, or the singular phenomena which both the lake itself and the surrounding country present to the observation of the naturalist. Those who have visited this wonderful place, seem at a loss for language adequate to the feelings which it excites when first beheld. After travelling through a vast extent of country, diversified by neither lake nor sea, the traveller at length reaches a chain of rugged mountains, which, forming an immense amphitheatre, enclose a lake that stretches far beyond the reach of sight, and, by the violent agitation and dreadful roaring of its billows, sometimes assumes all the magnificence of a mighty ocean, while, at other times, the clearness of its unruffled bosom emulates the lustre of the finest mirror.

The traces of those tremendous concussions, by which our world has once been agitated, are here extremely discernible. The lake itself can only be regarded as an enormous gulf, formed by the rending of the mountains, and intended by nature as a reservoir for her immense stores of water; while its rocky shores bear in almost every spot the visible marks of some terrible revolution, of which they indicate, at the same time, the remote antiquity. Its channel consists of the broken fragments of hills, the largest of which still rise above the surface in the form of islands. Its coast is one heap of broken rocks piled above each other to the height of forty fathoms. Cliffs, whose bases are sunk in unfathomable pits, lift their shattered summits to the clouds; and on the pinnacles of the loftiest mountains are found enormous stones in whimsical shapes, which could only be projected thither by some violent convulsion of the earth.

Nature seems to have exhausted herself by one great effort in forming the Baikal; for, though earthquakes are still frequent in the surrounding regions, they are in general so slight, that their shock is not felt at any considerable distance. The most remarkable effect of these earthquakes is visible in the lake itself, which even in the serenest weather, and while its surface is smooth as glass, sometimes undergoes the most violent internal agitations. At times, too, in a particular part of the lake, a single wave will suddenly rise, which is succeeded by several others in the same spot. Most of the phenomena, indeed, observable in the Baikal, seem to be peculiar and anomalous. The state of its surface is almost entirely independent of the violent storms to which it is subject. Even in a very moderate breeze it

often rages with alarming fury, while the strongest gales scarcely produce any perceptible increase of agitation.

These peculiarities render the navigation of this lake extremely hazardous; for, however inviting the weather may be, and however propitious the gale, a vessel may suddenly be wrecked by one of those violent commotions, which no sagacity can foresee, and no activity controul. Furious hurricanes, too, often burst in a moment from the surrounding mountains, and if, on these occasions, the bark happens to be in a narrow or shallow part of the lake, its destruction is inevitable. At a distance from the shore, the danger is less imminent; as in the middle of the lake there are no hidden rocks nor banks against which a vessel can strike. The mariners who navigate the Baikal have a compass peculiar to themselves, in which they distinguish only three winds. Those which blow between the north and south are called *Bargusin*, because they proceed from the direction of the river Bargusin: when they prevail, the passage is expeditious from the mouth of the Selenga to the opposite shore. Those which arise between the north-west and south-west are called *Koultouk*, as coming from the extensive bay of that name: while the north-winds, which are by far the most dangerous, are named *GORNATA POGODA*, or *winds of the mountains*; because the northern shore, from which they spring, is particularly mountainous.

The Baikal extends from the 51° to above the 55° of North latitude. It is upwards of 300 miles long, and its breadth varies from sixteen to fifty miles. Its depth, though unequal, is in some places incredibly great. In some of the central gulfs a line of more than three thousand fathoms could not reach the bottom; and Pallas mentions that from the middle of this lake to its northern shores, the depth was in general so immense, that a clue of packthread more than an ounce in weight was insufficient to sound it. Of the rivers that discharge themselves into the Baikal, the principal are the Upper Angara, the Bargusin, and the Selenga, which join it from the north, the east, and the south. The only outlet from this enormous reservoir is the Lower (or Great) Angara, which, bursting from its western side with impetuous rapidity, through a channel more than a mile broad, interspersed, too, with huge fragments of rock, presents a scene of awful sublimity, and stuns with its thundering noise the inhabitants of all the adjacent regions, to the distance of many miles. It cannot be supposed, however, that this single channel is at all adequate to the discharge of such a prodigious body of water; yet the lake seldom rises, even in the spring season, more than three feet above its ordinary level; so that it appears probable that part of it may be absorbed by some subterraneous drain. The water of the Baikal is so clear, that at the depth of eight fathoms the bottom is distinctly seen; yet at a distance it assumes a greenish hue. It is very agreeable to the taste, except in the month of July, when it is thrown into a kind of fermentation, called its flowering, which renders it somewhat nauseous, and gives it a turbid appearance, as if mixed with yellow sand.

A lake, distinguished by such bold and singular features, fills all who behold it with astonishment and awe; and is regarded by the superstitious inhabitants of the surrounding country with a very natural veneration. They dignify it with the name of the Holy Sea; and to call it simply a lake, they consider such a degree of pro-

fanity as cannot fail to provoke the immediate vengeance of heaven. A pilot, who had the hardihood to give it that contemptuous appellation, was tossed with his crew from shore to shore, till, exhausted by fatigue and hunger, and in danger of immediate shipwreck, he was at length compelled to implore the compassion of the Holy Sea. His prayers were heard—he reached the shore in safety; and from that moment never named the sea but with the most profound reverence. At a small distance from the lake there is a chapel dedicated to St Nicolas, to which the mariners repair to conciliate the favour of the saint by oblations, and to prefer vows and supplications for a prosperous voyage. As soon as they set sail, they throw various presents into the lake, either of money or of victuals, and if after all they happen to be overtaken by a storm, they uniformly ascribe it to the profanity of some Jonah on board.

In the neighbourhood of the Baikal the climate is extremely severe, owing chiefly to the elevation of the ground, and the want of sufficient shelter from the north winds. Scarce a night in the short summers which there diversify the year passes without frost; and even in August the approach of winter is announced by frequent falls of snow. The lake, however, is never frozen over till late in December, and the ice generally dissolves about the beginning of May. Ice-fields, several miles in length, are first formed in the bays, and while congelation is going on, the rest of the lake is covered with a thick fog, till the whole becomes one solid mass, which, according to the calmness or agitation of the surface during the process of freezing, is either smooth as a mirror, or so rough as to be scarcely passable. The violent winds prevent the snow from adhering to it, so that to travel over it at first is an undertaking of extreme difficulty. Sometimes the driver, while running by the side of his sledge, is thrown forward by a sudden squall, to the distance of several fathoms; and is thus in danger either of being frozen, or of falling into chinks still left in the ice. As the time of breaking up approaches, these chinks become wider and more frequent; boards are then laid across them for the accommodation of travellers, and when the apertures can no longer be passed in that manner, canoes begin to ply between the fields of ice. This dangerous mode of conveyance, however, is not long necessary; for, when the thaw once commences, the ice is very rapidly dissolved. In some of the bays, however, which are shaded by the impending mountains from the sun, large masses of ice lie unmelted throughout the whole summer.

Of the islands of the Baikal, which are not numerous, the most remarkable is the island Olkhon, near the northern shore, and separated from the main land by a sound. This island is 50 versts in length, and nearly ten in breadth, and is inhabited by about 150 families. It terminates in a promontory towards the north; on the south-east it is low and bare; but its south-western coast is finely diversified by groves of poplars, willow, birch, and pines. Here the pasture is so rich, that large droves of cattle are maintained through the whole winter, without any particular care or tending from the inhabitants, who spend almost their whole time in drinking, or in idleness.

The coasts of the Baikal present many objects which well deserve the attention of the naturalist. Springs, impregnated with sulphur and naphtha, are to be found in various places, many of them remarkable for their medicinal virtues. One of these springs, in particular,

opposite the western side of Olkhon, is so extremely copious, as to yield 582 gallons every hour. Its water, being highly sulphureous, has a loetid taste; and is so hot, that birds are boiled in it in the space of twelve minutes. In cutaneous disorders, this spring has been found to produce the happiest effects. It is employed for bathing, as well as taken internally. To the south of the Bargusin peninsula, there is a lake, called Dukhovoi, or *Vapoury*, the water of which is slimy and yellowish, and has a nauseous acid taste. The whole district is annoyed by its fetid exhalations; yet the water itself, when taken in a vessel, has no offensive odour. The lake even swarms with various kinds of fish, which are often stifled, however, during winter, when the putrid water is covered by an impenetrable coat of ice. Perhaps, therefore, the intolerable stench of this region may be owing, not so much to any peculiar quality in the lake itself, as to the quantity of fish that lie putrifying on its shores. Of all the mineral waters on the coast of the Baikal, none is more celebrated than the Turkobad, which, issuing from seven springs, some of them cold and others hot, flows into one reservoir, and is found very beneficial in many disorders. Near the same spot, there is found naphtha, which the lake throws out into the spring, incrustrated in lumps with ice, and sometimes two or three inches in diameter. It is a dark brown clammy substance, capable of being kneaded, soluble in water of a moderate heat, of a pleasant odour, and an excellent salve for wounds and running sores. These coasts likewise abound in alkaline salts of different kinds.

In enumerating the wonders of these regions, we must not forget a curious *lusus naturæ*, which is to be seen on the Shamane promontory. Three rocks, adjacent to one another, tower more than two hundred feet above the level of the lake; and their tops bear such a striking resemblance to human heads, that the Tunguses revere them as the sea-god Dianda, with his two subordinate deities. The nose of this Dianda, who stands between the other two, and overtops them considerably, is seven feet long; his eyebrows seem two projecting cliffs overshadowing his face; flocks of sea-fowl find harbour in his mouth; but he is altogether unprovided with ears. Notwithstanding this defect, however, his votaries believe that he hears acutely, and in all their fishing expeditions prefer to him their prayers, that he may save them from being drowned, and grant them a plentiful draught of fishes.

The plants most frequent in the sandy coast of the Baikal, and the neighbouring forest, are such as generally grow on very cold mountains. Those enumerated by Pallas, are the *finus cembra* the *empetrum nigrum*, the *campanula*, with round leaves and large flowers, the *fumaria imbricatis*, the *polygonum divaricatum*, the *polygonum sericeum*, a superb species of knotgrass, quite indigenous to the shores of this lake, the *scrophularia scorodonia*, the *dracocephalum nutans*, the *lycofisis vesicaria*, and the *triticum littorale*, which grows upon the shores in as great abundance as if it were sown, and is so like the gross kind of barley, that the peasants call it ДИКАЯ КОЧУ, or wild barley. Besides these, M. Pallas observed in the forest the *lonicera carulea et pyrenaica*, the *linnea*, the *rubus arcticus*, the *pedicularis paniculata*, the *ledum palustre*, the *andromeda polifolia*, and various kinds of *pyrola*, and among others the *pyrola uniflora*, called by the Siberians КИЛЛЕРЕКА. The growth of these plants is occasioned by the cold and hazy air which prevails during summer on the lake, the high mountains which

stretch along the southern part of the country, and the snow-clad summits which border the western side of the Baikal. In the lake itself there grows a kind of sponge, which is very sweet and thick, and has never been discovered in any other part of the world. In the language of the country it is called MORSKAYA SOUBA, or sea sponge; and Pallas has given it the name of *Spongia Baikalensis*. It is employed by the goldsmiths of Irkutsk to give the first polish to their silver-plate, and to vessels of copper and of brass.

The animal productions of the Baikal are still more curious and unaccountable than the wonders of its coasts. Of these, the most remarkable is a fish entirely peculiar to this lake, called by the Russians in that neighbourhood, СОЛОМЯНКА, and known to naturalists by the name of *Callygnomus Baikalensis*. It exactly resembles a clupe of blubber, and when exposed on a gridiron to the most gentle heat, melts so completely away, that nothing remains of it but a slender bone. It is impossible to catch these fish in nets, nor indeed are they ever seen alive. They seem to confine themselves to the deep gulfs in the centre of the lake, and are generally thrown up to the surface in summer, during the violent hurricanes which burst from the mountains. When the lake has been strongly agitated, they are forced up in such quantities as to form a kind of parapet upon the shore. They are so rank and oily, that neither sea-fowl nor ravens will touch their carcase, and after remaining near two hours on shore, are dissolved by a slight pressure in the hand. The oil made of their blubber is sold to the Chinese, who value it highly.

Seals, likewise, abound in the Baikal;—a very remarkable phenomenon, as these animals are never seen elsewhere at any distance from the ocean, nor do they frequent rivers or lakes of fresh water. It appears probable, therefore, that they have been introduced into this inland sea by some extraordinary revolution, which has produced a considerable change in the level of the globe. Their skin is of a silver grey, and their number is so great, that no fewer than two thousand are taken annually. The hunting of these animals commences in April. They assemble in great flocks, where the rapid currents, or warm springs, make chasms in the ice, and frequently come out of the water to bask and sleep in the sunshine. The hunters, who are perfectly acquainted with their haunts, place themselves in small sledges, which they conceal with a screen of white linen. As this screen perfectly resembles the ice, it can be moved towards the seals without alarming them; and the hunters, who are provided with muskets, can thus approach so near as to fire upon them without the possibility of missing their aim. Another mode of catching these animals was employed when that country was visited by Mr Bell of Antirionny. Holes were cut in the ice at certain distances, and nets were extended from one hole to another by means of long poles. The seals, unable to remain long under the ice, come to these apertures for air, and thus entangling themselves in the nets, became an easy prey.

But the most important fish in this lake is the Omul, which, both from its abundance and its excellent quality, is of inestimable benefit to all the surrounding country. The Omuls vary in size in different parts of the lake. Those caught near the mouth of the Selenga, rarely exceed two spans in length; while those which frequent the bay of Tschivirkoui, are represented by Pallas as enormous, though he does not state their particular di-

mensions. They bear a considerable resemblance to the herring, though Gmelin asserts, that the only property which they have in common with that fish is the glittering of their scales. Their flesh is white and tender; and they are so extremely delicate, that they die as soon as they are taken out of the water. They are generally caught in the month of October, and, instead of being salted, are left by the fishermen to stiffen with the frost, which enables them to convey them fresh to the various markets, and to sell them at a higher price. Towards the middle of August, they begin to divide into shoals, and to ascend the rivers for the purpose of spawning. It is remarkable, that they generally resort to the same stream in which they themselves were spawned, and there are some rivers that flow into the Baikal, which they never visit, though shoals of them may be seen near their mouths. They advance up the rivers very slowly, halting regularly where the current is least rapid; and when they reach the ice, they are compelled to return. This fish, to which naturalists have given the name of *salmo migratorius*, is not confined to the Baikal. They are supposed, indeed, to have come originally from the Frozen Ocean, from which they force themselves up the Yenisey, and several other rivers. Besides the species of fish which we have already mentioned, several other varieties are found in the Baikal, such as sturgeon, carp, and tench, devil's lampreys, (called by naturalists *salmo oxyrinchus*.) and lenki, or *salmo salvelinus*.

The fishery of this lake is farmed, and is extremely productive and valuable. It is prosecuted during the whole summer with large drag nets, upwards of two hundred fathoms long, to which is fastened a strong cord of about fifteen hundred feet. The net is drawn up by means of a windlass, to which the cord is attached. Pallas describes a net which is likewise employed on the Baikal, and which is precisely the same as the stake-nets used in our salmon fisheries. "These nets," says he, "are formed by a small enclosure (or park,) with branches which extend some fathoms into the water. At the extremity of this park there are other small ones, which form two oval chambers, which are entered by a sharp angle. This angle is formed by the two chambers and the park which descend from the shore. The fish, entering the park, proceed towards the bottom; they find at the angles a passage to penetrate into the chambers; they cannot get out, because the branches, or rods, are pointed at the opening, as in a net. This invention bears the name of KORSI. It is not known elsewhere." (k)

BAIKAL MOUNTAINS. These mountains follow nearly the same direction with the lake, accompanying it on both sides from south to north and north-east; and flattening on the west into a morassy steppe, or plain, of prodigious extent: to the east they stretch from the source of the Lena, along both sides of the river, till at length they dwindle away into a spacious ridge of fletz. This range is generally very high and craggy, consisting partly of granite, partly of flint-breccia, and lime-stone. Coal is frequently found in the lower regions of the Angara and Lena, where the fletz mountain greatly declines. A branch of this range seems to run westward through the region between the Podkammenia, and the Nishnaia Tunguska, away over the Yenisey; this branch probably consists of mere fletz mountains. Along the north-eastern part of the Baikal, the upper Angara, and the river Vitim, where lie the famous pits of Muscovy-glass, the mountain is wholly composed of granite. The mineral contents of these mountains are far from being tho-

roughly known. The principal minerals discovered in them are coals, asphaltum, sulphur sources, native sulphur, alum, common salt sources, lapis lazuli, Muscovy-glass, cornelians, natural prussian blue, and specimens of iron, copper, and lead. Some of the Baikal mountains are so high, that they are clad in eternal snows. Some of the cliffs, which tower above the surface of the lake, consist of solid white quartz. The mountains, though partly bare, are in general covered with forests, and present many scenes no less beautiful than sublime. They contain the sources of many noble rivers, the principal of which are the Selenga, the Angara, the Lena, the Vilui, and the Tungusa. See Tooke's *View of the Russian Empire*, vol. i. p. 166, 170, 241, 242; and vol. iii. p. 170, 171. *Voyage de Pallas*, octavo, vol. v. p. 220, 226; and vol. vi. p. 108, 123. BAIL, in law, (from the Fr. *bailler*, to deliver,) signifies the security given for the defendant's appearance in a process.

Bail is given both in civil and in criminal actions. In civil cases, bail is either *common* or *special*. Common bail is taken when the defendant has been served with a writ of *capias*, by the sheriff or his officer, and with notice to appear by his attorney in court, to defend the action. If the defendant thinks proper to appear upon this notice, his appearance is recorded, and he puts in sureties for his future attendance and obedience. These sureties are called *common bail*, being the same two imaginary persons, John Doe, and Richard Roe, that were pledges for the plaintiff's prosecution. And if the defendant does not appear upon the return of the writ, or within a short period after, the plaintiff may enter appearance for him, and file common bail in his name, as if the defendant had done so himself.

Common bail is taken only in actions of small concernment. But in causes of greater weight, such as actions upon bond or speciality, &c. where the plaintiff makes affidavit, or asserts upon oath, that the cause of action amounts to 10*l.* or upwards, the defendant must put in substantial sureties for his appearance, which is called *special bail*. And in such cases it is required by statute 13 Car. II. st. 2. c. 2, that the true cause of action should be expressed in the body of the writ or process.

Upon the return of the writ, or within four days after, the defendant must *appear*, according to the exigency of the writ. This is done by putting in and justifying bail *to the action*; which is commonly called putting in bail *above*. If this appearance be not made, and the bail taken by the sheriff *below* are responsible persons, the plaintiff may then take from the sheriff an assignment of the bail-bond, and bring an action against the sheriff's bail. And if the bail accepted by the sheriff be insolvent persons, the plaintiff may have recourse against the sheriff himself.

The bail *above*, or bail *to the action*, must be put in either in open court, or before one of the judges of that court; or, if in the country, before a commissioner appointed for that purpose, and transmitted to the court. The bail, or sureties, to the number of two, at least, must enter into a recognizance before the judge or commissioner, whereby they jointly and severally undertake, that if the defendant be condemned in the action, he shall pay the costs and condemnation, or render himself a prisoner, or that he will pay it for him: which recognizance is transmitted to the court in a slip of

parchment, entitled a *bail-fiance*. And the bail, if required, must *justify* themselves in court, or before the commissioner in the country, by swearing that they are housekeepers, and each of them worth double the sum for which they are bail, after paying all their debts. This practice is in some degree analogous to the *stipulatio* or *satisfactio* of the Roman law.* *Inst.* l. 4. t. 11. ff. l. 2. t. 8.

Bail, in criminal cases, is taken in most offences inferring an inferior degree of guilt; but not in felonies, and other capital crimes, because, in these cases, no bail could be a security equivalent to the actual custody of the offender's person. Both by the common and statutory laws, it is an offence against the liberty of the subject, for any magistrate to refuse or delay to bail any person bailable; and it is expressly declared, by statute 1 W. & M. st. 2. c. 1, that excessive bail ought not to be required; † but it must be left to the courts to determine, according to the circumstances of the case, what bail shall be called excessive. Bail may be taken either in court, or, in some particular cases, by the sheriff, coroner, or other magistrate, but most frequently by the justices of the peace.

Bail can be taken only where the imprisonment is for safe custody, before conviction, and not from prisoners already convicted. By the old common law, all felons were bailable, till murder was excepted by statute; so that persons might be admitted to bail, before conviction, almost in every case. But the power of bailing in treason, and in divers instances of felony, has been taken away by sundry statutes.

The offences not bailable, according to Sir William Blackstone, are: 1. Treason; 2. Murder; 3. Manslaughter, if the prisoner be clearly the slayer. 4. Persons committed for felony, who have broken prison; 5. Outlawed persons; 6. Such as have abjured the realm; 7. Approvers, and persons by them accused; 8. Persons taken with the mainour, or in the fact of felony; 9. Per-

* The *special bail* of the common law is analogous to the civil law stipulation *judicio sisti*, to be present in court and abide by the final judgment of the cause, but it differs from that of *judicatum solvi*, by which the fidejussor is bound to pay the amount which the tribunal may award. In the United States, the practice of special bail in civil actions, obtains with very little variation, in the same manner as in England. Bail is not, however, always taken in double the sum sworn to by the plaintiff: in some of the states, and particularly in Pennsylvania, it is sufficient if bail is given in the amount of the debt, and as much more as will be amply sufficient to cover the interest and costs. But bail is demanded of the defendant in every suit for the payment of money, however small the sum may be, and in this the law of England, which does not require bail to be given for debts under 10*l.* is certainly more humane. In the state of Pennsylvania, freeholders are exempt from giving special bail; they cannot, except in certain cases, be sued by *capias*, but must be proceeded against by writ of summons; which is conformable to the rule of the civil law, *possessores immobiliarum rerum satisfacere non compelli*. ff. l. 2. t. 8. l. 15.

DE PONENTE.

† There is a similar provision in the constitution of the United States, and in the constitutions of the different states. *Ibid.*

sons charged with arson; 10. Excommunicated persons, taken by writ *de excommunicato capiendo*. The following are of a dubious nature, and it seems to be left to the discretion of the justices, whether they are bailable or not: 1. Thieves openly defamed and known; 2. Persons charged with other felonies, not being of good fame; 3. Accessories to felony, that labour under the same want of reputation. The following *must* be bailed upon offering sufficient surety: 1. Persons of good fame, charged with a bare suspicion of manslaughter, or other inferior homicide; 2. Such persons, charged with petit larceny, or any felony not before specified; or, 3. With being accessory to any felony. It is agreed, however, that the court of King's Bench, or any judge of that court in time of vacation, may bail for any crime whatsoever, whether treason, murder, or any other offence, according to the circumstances of the case. See Blackst. *Comment.* Jacob's *Law Dict.* (z)

BAILIFF, (from the Lat. *ballivus*; * Fr. *baillif*, i. e. *Præfectus provincie*) signifies an officer appointed for the administration of justice within a certain district. The office, as well as the name, appears to have been derived by us from the French; and it is probable that our sheriffs of counties were also anciently called *bailiffs*, as the county is still often called *balliva*, or *hailwick*. In the statute of Magna Charta, c. 28, and 14 Edw. III. c. 9, the word *bailiff* would appear to comprehend sheriffs, as well as bailiffs of hundreds. As the kingdom is divided into counties, so every county is divided into hundreds, within which, anciently, the people had justice administered to them: by the several officers of every hundred, who were the bailiffs. And it appears from Braeton, (lib. iii. tract. 2. cap. 34) that bailiffs of hundreds might anciently hold plea of *appeal* and *approvers*. But these hundred courts, certain franchises excepted, have been, since that time, swallowed up by the county courts: and the bailiff's name and office is now grown into contempt, they being, in general, merely officers or messengers employed to serve writs, &c. within their liberties. In other respects, however, the name is still in good esteem; the chief magistrates in many towns

* There is no such word as *ballivus* in the Latin idiom; it is a barbarism of the same species with *attornatus*, on the subject of which see note to the word *attorney*. It is more probable that *ballivus* is derived from *baillif*, than the latter from the former. The true origin of both appears to be from the Italian *balia*, power, authority, and *balio*, *baillio*, a magistrate, which name not long ago was still given to the Venetian ambassador at the Poite, and by courtesy to the foreign consuls throughout the Levant. A *bailiff* originally was, as defined in the article to which this note refers, "an officer appointed for the administration of justice within a certain district." Most of the countries of Europe were formerly divided into bailiwicks, being districts of moderate size, like the counties in England, under the government of a civil officer, called in the southern languages of Europe *balio* or *bailiff*, and in the northern *Vogt* or *Amtmann*. France before the late revolution was divided into similar districts called *baillivages*, and that was the proper territorial division of the country for the purpose of national representation in the states general, and for the primary administration of justice. The American states for similar purposes are also divided into counties, which in legal proceedings are sometimes called *bailiwicks*. DE PONCEAU.

being called bailiffs: and sometimes the persons to whom the care of the king's castles is committed are termed bailiffs; as the Bailiff of Dover Castle, &c.

The ordinary bailiffs are of several sorts.

Bailiffs of Liberties, are those who are appointed by every lord within his liberty, to execute processes, &c. Bailiffs of liberties and franchises are to be sworn to take distresses, truly impanel jurors, make returns by indenture between them and sheriffs, &c. and shall be liable to punishment for malicious distresses, by fine and treble damages. 12 Edw. II. st. 1. c. 5; 14 Edw. III. st. 1. c. 9; 20 Edw. III. c. 8; 1 Edw. III. st. 1. c. 5; 2 Edw. III. c. 4; 5 Edw. III. c. 4; 11 Hen. VII. c. 15; 27 Hen. VIII. c. 24; 3 Geo. I. c. 15. § 10.

Bailiffs of Sheriffs, or sheriff's officers, are either bailiffs of hundreds, or special bailiffs. Bailiffs of hundreds are officers appointed by the sheriffs to collect fines in their respective districts; to summon juries; to attend the judges and justices at the assizes and quarter sessions; and also to execute writs and processes in the several hundreds. But as these bailiffs of hundreds are generally plain men, and not thoroughly skilful in this latter part of their office, it is now usual to join *special bailiffs* with them. The sheriff being answerable for the misdemeanors of these bailiffs, they are therefore usually bound in a bond for the due execution of their offices, and are thence called *bound bailiffs*; which the common people have corrupted into a much more homely appellation.

Bailiffs of lords of manors, are those that collect their rents, and levy their fines and amercements, &c.

Bailiffs of Courts Baron, summon those courts, and execute the process thereof, &c.

Bailiffs of husbandry, are the officers belonging to private persons of property, who superintend the inferior servants, regulate their labour, &c.

Bailiff, Water, is an officer anciently established in all seaport towns, for the searching of ships. 28 Hen. VI. c. 5.

Such an officer still exists in the city of London, who supervises and searches all fish brought thither, and gathers the toll on the river Thames. He also attends the Lord Mayor in his excursions by water, and marshals the guests at table. He can also arrest for debt, &c. on the river Thames, by warrant of his superiors.

There are different other denominations of bailiffs to be met with in this and other countries; such as, *provincial, royal, itinerant, and heritable bailiffs*; *bailiffs of France*, of the empire, of boroughs, &c. See Blackst. *Comment.* Jacob's *Law Dict.* (z)

BAILLY, JEAN SYLVAIN, a celebrated French astronomer, was born at Paris on the 15th September 1736. A genius for painting having been hereditary in the family for four successive generations, Bailly was bred to the profession of his ancestors, and made considerable progress in that delightful art. A passion, however, for poetry, and other branches of literature, distracted the attention of the young artist, and unfitted him for that intense and undeviating application to the practice of his art, which can alone raise the painter to opulence and fame.

The friends of Bailly soon perceived that his mind was bent upon subjects foreign to his profession, and regretted that a genius so promising and ardent should be chained down to the practice of an art, when it aimed at the highest flights of literature and science. An accidental acquaintance with the celebrated astronomer

La Caille, determined the general train of his studies, and inspired him with the most passionate enthusiasm for the science of astronomy. His first effort in this new career was the calculation of the orbit of the famous comet of 1759, which was published in the memoirs of the academy for that year. On the 29th January, 1763, Bailly was admitted a member of the academy of sciences, and in the same year he published three memoirs on the theory of Jupiter's satellites, and his reduction of the numerous observations made by La Caille in 1760 and 1761, on 515 zodiacal stars. These reductions were published in 1763, at the beginning of the Ephemerides computed by La Caille for the years 1765—1774.

The importance which was now attached to the method of finding the longitude by the eclipses of Jupiter's satellites, turned the attention of astronomers to the theory of these secondary planets. This interesting subject was proposed by the academy as the prize question for 1764, and Bailly engaged in the investigation with the utmost ardour. In the illustrious La Grange, however, who was almost exactly of the same age with himself, he found a formidable and a successful rival. In applying the problem of the three bodies to the satellites of Jupiter, Bailly considered only the action of one satellite upon another, while Le Grange viewed the subject in a more general aspect, and took into account the mutual derangements of all the four satellites. The results of Bailly's investigations were published in 1766, in a separate treatise, entitled, *Essais sur la Theorie des Satellites de Jupiter, suivis des tables de leur mouvement*; which likewise contained the history of that branch of astronomy. In this treatise he happened to mention as his own, the discovery of the cause of the variation in the inclination of the orbits of Jupiter's satellites. This circumstance occasioned a dispute between him and La Lande, who laid claim to the same discovery. Bailly asserted his own claim in the *Journal Encyclopedique* for June 1773, but he had afterwards the candour to state in his history of astronomy, the opposite claims of La Lande and himself, and to leave the subject to the decision of his readers.

The difficulty of finding the exact instant of the immersions and emersions of the satellites of Jupiter, stimulated Bailly to make a number of observations on this curious subject, which he has published in an interesting paper in the memoirs of the academy for 1771. The great discrepancy which was perceived in the observation of these eclipses, obviously arose from the diameters of the satellites, and from the different apertures of the telescopes with which they were observed.* In order to determine the exact diameters of the satellites, Bailly observed an immersion with a telescope, whose aperture was so much contracted that the satellite could scarcely be seen, so that it became entirely visible when the smallest portion of its diameter had entered into the shadow. He then observed the immersion of the same satellite with the whole aperture of the telescope, and from the interval of time which elapsed, he obtained the values of the diameters of the satellites, which we have given in ASTRONOMY, Table LX. p. 813.

Bailly had long meditated an extensive work on the

history of astronomy, and in the year 1775, he completed the first volume of that profound work, entitled, *Histoire de l'Astronomie Ancienne*. The second and third volumes, entitled, *Histoire de l'Astronomie Moderne*, appeared in 1779, and the fourth in 1782, which completed the history of ancient and modern astronomy. The return of M. Gentil from India, with a new set of astronomical tables, the epochs of which extend to such a remote period as the year 3102 before Christ, attracted the attention of philosophers to this curious branch of the history of astronomy. These tables were put into the hands of Bailly, who diligently compared them with modern observations, and who found that they must either have been constructed from actual observation, or that the Indians must have been acquainted with the most refined and intricate theories of physical astronomy. The profound researches, the nice calculations, and the ingenious and acute reasonings by which he has supported the antiquity of the Indian astronomy, were published in 1787, in his *Traité de l'Astronomie Indienne et Orientale*, which completed the great work to which his life had been devoted.†

The *Histoire de l'Astronomie*, by Bailly, is perhaps one of the most interesting books that has ever been written upon a scientific subject. His ingenious speculations respecting the early history of astronomy;—the copious brilliancy of his descriptions;—the eloquence with which he pleads the cause, and paints the sufferings of neglected genius;—and the glowing imagery with which his lively fancy every where embellishes the general narrative, throw an air of enchantment round the most common details. Even amid the driest enumeration of facts, the attention is perpetually arrested and kept alive by the most delicate touches of nature, and by the nicest discrimination of character. The loose and scattered materials which the history of astronomy often presents, are chained together in one connected narrative, and one astronomer follows another, and new discoveries spring from those which precede them, as if the progress of discovery had been under the controul of causes less accidental than those which nature has prescribed. But it is in those great and general views which constitute the peculiar province of philosophy, that Bailly shines above all praise. In tracing the effects of moral causes and political institutions on the advancement of astronomy, and on the general progress of our species;—in painting the baneful effects of an unholy superstition upon the happiness and improvement of mankind;—in describing those alternate periods of languor and renovation, which accompany the mighty convulsions of nations, which follow the tyranny or munificence of princes, or in which the human mind, without any apparent cause, sinks into torpid inactivity, or soars beyond its wonted flight;—in marking the connection between the various sciences, and estimating the mutual aid which each imparts to the advancement of the rest;—and in anticipating the conquests which human genius has yet to achieve over vice and error, throughout every region of Nature—Bailly rises to a sublimity of eloquence, which could be inspired only by the powerful interest which he felt for the progress of science, and for the happiness of his fellow creatures.

* On the 25th January 1762, Maraldi observed the immersion of the fourth satellite at $6^h 16^m \frac{1}{2}$, with a good telescope of 15 feet, while Messier, with a Gregorian telescope of 30 inches, observed the same immersion, at $6^h 29^m$. See ASTRONOMY, part. i. chap. i. sect. xi.

† A general view of the arguments employed by Bailly and Professor Playfair, in defence of the authenticity of the Indian tables, will be found in the history of ASTRONOMY, p. 585.

Besides this extensive work, Bailly published the following papers in the Memoirs of the French Academy. "Memoir on the Epochs of the Moon's Motions at the end of the last Century." "On the Comet of 1762." "Astronomical Observations made at Nolson 1764." "On the Eclipse of the Sun of the 1st April 1764." "Observations made at the Louvre, from 1760 to 1764." "On the Cause of the Variation of the Inclination of the Second Satellite of Jupiter." "On the Motion of the Nodes, and on the Variation of the Inclination of Jupiter's Satellites." "Essay on the Theory of the Satellites of Jupiter." "Observations on the Opposition of the Sun and Jupiter." "On the Equation of Jupiter's Centre," &c. "On the Transit of Venus in 1769, and on the Eclipse of the Sun on the 4th June of the same year."

Like D'Alembert, his illustrious contemporary, Bailly was highly distinguished by his literary attainments. His Eloge upon Leibnitz, published in 1768, carried off the prize of the Academy of Berlin, and the eloges which he composed upon Charles V., Corneille, La Calle, Cook, Moliere, and Gresset, extended his reputation as an elegant writer. The speculations contained in the first volume of his History of Astronomy, respecting the early state of Upper Asia, led to a correspondence with Voltaire; the substance of which he afterwards published in two volumes, the first of which was entitled, *Lettres sur l'Origine des Sciences, et sur celle des Peuples de l'Asie*, Paris 1777; and the second, *Lettres sur l'Atlantide de Platon, et sur l'ancienne Histoire de l'Asie*, Paris, 1779. These two works, and the Eloges already mentioned, were published in two volumes in 1770, under the title of "Discourses and Memoirs;" and were reprinted in 1790, along with other discourses of Bailly, that had been pronounced when he was President of the National Assembly, and Mayor of Paris.

A similarity of opinion with the celebrated Buffon, occasioned such an intimacy between Bailly and that able naturalist, that when the office of secretary to the Academy of Sciences became vacant in 1771, Bailly offered himself as a candidate, and was supported by all the influence of Buffon. The interest of D'Alembert, however, was powerfully exerted in favour of Condorcet, and Bailly lost his election. He did not, however, long enjoy the friendship of Buffon. The opposition which he made to the admission of the Abbé Maury into the French Academy, irritated Buffon, and dissolved the friendship which they had mutually cherished. Besides those works which we have already mentioned, Bailly composed in the years 1781 and 1782, a work on the Fables and religious creeds of antiquity, entitled, *Essai sur les Fables et sur leur Histoire*, two volumes of which were published in 1799.

In the year 1784, Bailly was elected secretary of the French Academy, and, in 1785, he was chosen a member of the Academy of Inscriptions and Belles Lettres; the only case since the time of Fontenelle, in which the same person was at once a member of the three learned academies which then flourished in Paris.

The public attention having been attracted to the subject of Animal Magnetism, Bailly was appointed a member of the committee for examining the miraculous effects which were said to be produced by this new art. The report which he drew up for the Academy of Sciences was translated into English, and was universally admired for the elegance of its composition, and the

sound philosophy which it displayed in developing the effects produced upon the body, by the influence of moral causes.

In the year 1786, a committee was appointed by the academy, to examine a plan for a new hotel-dieu by the architect Poyet. Bailly, who was one of the number, drew up a long report, of 250 pages, which did great credit to the genius and the humanity of its author.

It would have been fortunate for Bailly had his life now terminated, when worn out with the labours of science, and loaded with the high rewards which are reserved for genius and learning. A fatal necessity, however, dragged him from the hallowed retreats of philosophy upon the stage of public life, and compelled him to act a conspicuous and a zealous part in that bloody struggle by which his countrymen sought for the blessings of a free government. Those who have witnessed the atrocities of this barbarous revolution, and have seen it terminating in a military government, more oppressive than the despotism of the House of Bourbon, may well question the prudence of a people who throw themselves loose from the wholesome restraints of the law, and seek for a reformation of their government from the assistance of an unbridled populace, and amid the selfish tumults of contending factions. But they are not entitled to sit in severe judgment upon the conduct of those who listened to the groans of an oppressed people, and who lent the courage of their hearts, and the vigour of their minds, to impose a salutary check upon the licentiousness of arbitrary power, and to establish, without the waste of blood, the eternal and immutable principles of rational freedom. Bailly was one of those true patriots, who panted for the deliverance of his country, and proffered his most ardent exertions in her sacred cause. On the 26th of April 1789, he was chosen secretary by the electors of Paris; and when the states-general assembled in the same year, he was elected deputy to the *Tiers Etat*, or Commons, and was afterwards appointed president of that magnanimous body. When the National Assembly was constituted, Bailly was appointed president for four days. The proclamation of the king to disperse this illegal combination, bound together by new ties the members of the National Assembly. They resolved to assert the rights of the people; and Bailly dictated the famous oath to the members of the *Tiers Etat*, "that they would resist tyrants and tyranny, and would never separate till they had obtained a free constitution." On the 15th of July 1789, the day after the surrender of the Bastille, M. Bailly was appointed, by general acclamation, Mayor of Paris, an office which had long been dormant. The courage which he displayed in fulfilling the duties of this high trust, was uniformly tempered with moderation; and while in the rigorous execution of the laws, he avoided the extreme of harshness and cruelty, he never forgot the imperious duty of forwarding the views of the popular party, and baffling the plans of the court faction, who resisted every restraint, however rational, upon despotic power. In testimony of the high esteem in which his public conduct was held, his bust was placed with great pomp in the municipality, and likewise in the academy of sciences, where those of living academicians had never before been admitted.

Though a deserved favourite with the people, the temperate measures which he pursued did not well accord with the passions of an unbridled mob, from whom

the letters of despotism had been but newly broken. Bailly saw with regret, the dreadful extreme to which their fury was hurrying them on. He resolved to make one effort for the preservation of tranquillity, and hoped that by measures of decisive energy he might yet oppose an effectual barrier to the swelling tide of universal anarchy. He therefore opposed the violent proceedings of Marat and Hubert. He arrested the deputies from the military insurgents at Nancy. He exerted himself to persuade the populace to allow the royal family to depart for St Cloud; and on the 17th July, 1791, when the mob demanded the abolition of monarchy, and assaulted the troops that were called out to disperse them, he ordered the soldiers to fire, by which about forty persons were killed, and above four hundred wounded. By these measures he lost the favour of the populace, and resigned the mayoralty on the 16th November 1791, when the constituent assembly was dissolved.

The ill health into which he had now fallen, induced him to travel through different parts of France in 1792 and 1793, and to pursue in the bosom of peaceful retirement those delightful researches which the political convulsions of his country had so cruelly interrupted. During this seclusion, he amused himself in composing memoirs of the events in which he bore such a conspicuous part;* and when employed in this occupation, he was arrested by the orders of Robespierre, and condemned to death on the 10th of November, 1793. Clothed in the red shirt, Bailly was placed in a cart, with his hands tied behind his back, and driven to the fatal guillotine, erected on the spot where he had ordered the military to fire upon the people. The very populace who had once adored him, and whose best interests he had so near his heart, threw mud upon him as he passed, and followed him with the most insulting reproaches; whilst the cold rain incessantly poured on the grey head of the venerable sage. Having reached the fatal spot, it became necessary to remove the guillotine to firmer ground. During this operation, Bailly was taken from the cart, and compelled to walk round the field, to glut the insatiable cruelty of the mob. The brutal multitude spit upon him as he passed, and, notwithstanding the exertions of the executioners, some of them even struck him upon the face. When the apparatus of death was again prepared, Bailly, drenched with rain, and shivering with cold, ascended the platform. "You tremble, Bailly," cried one of the mob, in a tone of insult. "I tremble, it is true," replied the philosopher, "but not with fear."

Such were the last words of a man, who, during a life of 57 years, acquired the highest reputation as a philosopher and an elegant writer. Even in the turmoils of a political life, so foreign to his temper and his studies, he obtained the approbation of the most opposite factions, and left behind him a character of the most disinterested integrity. When he held the office of mayor, he spent part of his fortune in relieving the wants of the poor; and he exhibited the same affectionate disposition in educating eight nephews with all the tenderness of a father. The person of Bailly was considerably above the middle size, his deportment was sedate and grave, and his countenance expressed the intelligence and the goodness which he possessed. In the year 1787, he married Jeanne Leseigneur, the widow of Raymond Gaye, the treasurer of the clergy, who had been his intimate friend for 25 years. See Bailly *l'or.*

De l'Astronomie, tom. iii. p. 69, 70, 133. *Journal Encyclopedique* de Juin 1777. *Decade Philosophique, litteraire et Politique*, 13 Fev, 1795. *La Lande Bibliographique Astronomique*, p. 730. Rioulle, *Memoires d'un Detenu.* (2)

BAILMENT, in the law of England, is a delivery of goods in trust, upon a contract expressed or implied, that the trust shall be faithfully executed on the part of the bailee, to whom they are delivered, and that the goods shall be restored, as soon as the purposes of the trust are fulfilled.

Bailment comprehends, 1. Deposit; 2. Loan (*mutuum, accomodatum*); 3. Hire (*locatio or conductio*); 4. Pledge; 5. Carriage of goods for reward; 6. Mandate, or acting by commission.

In Bailment there is a special qualified property transferred from the bailor to the bailee, together with the possession. It is not an absolute property in the bailee, because of his contract for restitution; and the bailor hath nothing left in him but the right to a *chose in action*, grounded upon such contract, the possession being delivered over, in the mean time, to the bailee. The bailee being responsible to the bailor, if the goods should be lost or damaged by his wilful default or gross negligence, it is reasonable that he should have a right to recover either the specific goods, or else a satisfaction in damages, against all other persons who may have purloined or injured them. The degree of responsibility undertaken by the bailee, and the species of diligence which he is bound to use in the performance of the trust, will depend upon the specific nature of the contract. See sir William Jones's *Essay on the Law of Bailment*; Blackst. *Comment.*; Jacob's *Law Dict.* (2)

BAILYBOROUGH, a market town of Ireland, in the county of Cavan, celebrated for a lake or pool on the summit of a mountain in its neighbourhood, remarkable on account of the antiscorbutic virtues of its water, and of the mud which is deposited at its bottom. The mud, which is a greasy substance like tar, is brought up from a depth of 30 feet, and rubbed on the parts affected. The water has a chalybeate taste, and is pure to the depth of about 6 feet. The temperature is said to suffer no change either in summer or winter. See Cootes' *Statistical Survey of Cavan.* (j)

BAIRAM, the *Greater* and the *Lesser*, the name of two annual festivals among the Mahometans. See Sale's *Koran, Prelim. Dissert.* p. 150. (j)

BAIROUT, or **BAYREUTH**, the *Berytus* of the ancients, a town of Syria, situated near the foot of Mount Lebanon, and remarkable only as being the emporium of the commerce of the Maronites and Druses, who export to it their cottons and silks, and receive in return rice, tobacco, coffee, and specie. These articles are again exchanged for the corn of the Bekaa, and no fewer than 6000 persons are employed in this commerce. A full account of this insignificant town will be found in Volney's *Travels in Egypt and Syria*, vol. ii. p. 187. (j)

BAIT-EL-LAHAM, the name of the ancient Beth-lehem. See Volney's *Travels*, vol. ii. p. 323, and **BETH-LEHEM**.

BAITING. See **BULL-BAITING**.

BAKEWELL, called **BADECANWYLLAM** in the Saxon chronicle, is a market town in the hundred of High Peak, in the county of Derby, situated on the river

* These **Memoirs**, which are expected to be soon published, occupy 600 quarto pages, and come down to the 2d October 1789.

Wye, near its confluence with the Derwent. The church is an elegant piece of architecture, with a lofty spire resting upon an octagonal tower. From several pieces of antiquity dug up in the neighbourhood, Baking seems to have been built in the time of the Romans. Near the town is a large cotton mill, erected by sir Richard Arkwright, which gives employment to near 400 persons. Number of houses 280; population 1412, of which 523 are employed in trade. See the *Beauties of England and Wales*; and DERBYSHIRE. (q)

BAKING, the art of reducing meal or flour of any kind, or any other substance, into bread. This art, simple and necessary as it may appear, does not seem to have been discovered till a late period in the history of mankind. The earlier nations knew no other use of their meal than to make of it a kind of porridge. Such was the food of the Roman soldiers for several centuries, or at most their skill proceeded no farther than to knead unleavened dough into biscuits or cakes. Even at present there are many countries where the luxury of bread is unknown. To bake it properly requires many precautions, and a degree of skill which can only be gained by considerable practice.

It is owing, perhaps, to this circumstance, that those who first began to pursue baking as a profession, have, in their several nations, been held in very high respect. At Rome, into which regular bakers seem to have been introduced from Greece, about the year of the city 583, they were so much esteemed as to be occasionally admitted into the senate. To preserve them more upright and honourable, they were expressly forbidden to associate with gladiators or comedians; and to enable them to devote their whole time to their proper business, they were exempted from guardianships and other offices to which the rest of the citizens were liable. To the foreign bakers who first practised this art in Rome, a number of freedmen were added, forming together an incorporation, or college, from which neither themselves nor their descendants were allowed to withdraw. Even their effects were held in common, and no part of them could be alienated. Each bake-house was under the superintendance of a patron, and one of the patrons was annually elected to preside over the rest, and take charge of the general concerns of the college. By the statutes of England, too, bakers are considered as superior to the general order of handicrafts. "No man," says the 22d Henry VIII. cap. 13. "for using the mysteries or sciences of baking, brewing, surveying, or writing, shall be interpreted a handicraft." In London, and indeed in most of the towns throughout the kingdom, they are under the jurisdiction of the magistrates, who regulate the price of bread, and have the power of fining those who do not conform to their rules. The two kinds of bread made in London are distinguished by the names of white, or wheaten, and household, which differ only in their degrees of purity. Every baker is liable to a penalty if he does not mark his loaves, according to their different qualities, with the letters W or H.

The ingredients of bread are flour, yeast, water, and salt, which are mixed according to the following process: To a peck of flour are added a handful of salt, a pint of yeast, and three quarts of water, which in hot weather must be cold, in winter hot, and in temperate weather lukewarm. The oven must be heated more than an hour before the bread is introduced, which must remain there three hours to be properly baked. The

peck-loaf, whether household or wheaten, must weigh seventeen pounds six ounces avoirdupois, and smaller bread in the same proportion. Every sack of flour must weigh two hundred weight and a half; and from this there should be made, at an average, twenty peck loaves, or eighty common quartern loaves. Formerly, if the bread was deficient only one ounce in thirty-six, the baker was liable to the pillory; and the same offence is now punished by a fine imposed at the will of the magistrates, provided it be not more than five shillings, nor less than one for every ounce wanting. Suspected bread, however, must be weighed before a magistrate within twenty-four hours after being baked; as its weight diminishes the longer it is kept. For further particulars concerning bread, and the substitutes used for it in various nations, see BREAD. (v)

BAKU, or **BACCOR**, a sea-port town of the Caspian Sea, situated in the province of Schirvan in Persia. Although the entrance to the harbour is beset with shallows, islands, and sand banks, yet it is reckoned the safest in the Caspian, as ships can be moored head and stern, in seven fathoms of water, at the distance of forty fathoms from the shore, under the command of two strong bastions. The town, which is said to have been built by the Turks, is defended by a double wall, by strong redoubts, and by a dry ditch, which can be filled in twenty four hours with water from the adjoining mountains. On the north and west of the town are several lofty and rugged mountains, with strong watch towers built upon their summits. The rock-salt, brimstone, and naphtha, which are found in the neighbourhood of Baku, are carried to Ghiland, Mazenderas, and the surrounding countries. Saffron is also produced in great quantities. The trade of Baku is chiefly carried on with Shamachy, from which they receive an excellent red wine, and silks and silken stuffs.

Among the curiosities in the neighbourhood of Baku, is what is called the *everlasting fire*. About ten British miles north-east of Baku, where the land is dry and rocky, there are several small ancient temples, or arched vaults, about ten feet high, supposed to have been dedicated to fire. In one of these, where the Indians now worship, a large hollow cane is fixed to the ground near the altar, and from the extremity of it issues a blue flame, more gentle than that which is produced from spirits of wine, which the Indians suppose has burned since the flood, and will continue till the end of the world. From a horizontal gap on an adjoining rock, about 60 feet long and three broad, there issues a blue flame of a similar kind. According to Gmelin, the soil is a coarse marl mixed with sand, and effervesces with acids. The following interesting account of the naphtha springs is taken from Hanway's Travels, and shall be given in his own words. The revenue arising from them to the Khan of Baku has been computed at no less than forty thousand rubles.

"The earth round this place, for above two miles, has this surprising property, that by taking up two or three inches of the surface, and applying a live coal, the part which is so uncovered immediately takes fire, almost before the coal touches the earth: the flame makes the soil hot, but does not consume it, nor affect what is near it with any degree of heat. Any quantity of the earth carried to another place does not produce this effect. Not long since eight horses were consumed by this fire, being under a roof where the surface of the ground was turned up, and by some accident took flame.

If a cane, or tube even of paper, be set about two

inches in the ground, confined and close with the earth below, and the top of it touched with a live coal, and blown upon, immediately a flame issues without hurting either the cane or the paper, provided the edges be covered with clay; and this method they use for light in their houses, which have only the earth for the floor: three or four of these lighted canes will boil water in a pot, and thus they dress their victuals. The flame may be extinguished in the same manner as that of spirits of wine. The ground is dry and stony; and the more stony any particular part is, the stronger and clearer is the flame; it smells sulphurous like naphtha, but not very offensive.

Lime is burnt to great perfection by means of this phenomenon; the flame communicating itself to any distance where the earth is uncovered to receive it. The stones must be laid on one another, and in three days the lime is completed. Near this place brimstone is dug, and naphtha springs are found.

The chief place for the black or dark goez naphtha is the small island Wetoy, now uninhabited, except at such times as they take naphtha from thence. The Persians load it in bulk in their wretched vessels, so that sometimes the sea is covered with it for leagues together. When the weather is thick and hazy, the springs boil up the higher; and the naphtha often takes fire on the surface of the earth, and runs in a flame into the sea, in great quantities, to a distance almost incredible. In clear weather the springs do not boil up above two or three feet: in boiling over, this oily substance makes so strong a consistence as by degrees almost to close the mouth of the spring; sometimes it is quite closed, and forms hillocks that look as black as pitch; but the spring which is resisted in one place breaks out in another. Some of the springs which have not been long opened form a mouth of eight or ten feet diameter.

The people carry the naphtha by troughs into pits or reservoirs, drawing it off from one to another, leaving in the first reservoir the water, or the heavier part with which it is mixed when it issues from the spring. It is unpleasant to the smell, and used mostly amongst the poorer sort of the Persians, and other neighbouring people, as we use oil in lamps, or to boil their victuals, but it communicates a disagreeable taste. They find it burn best with a small mixture of ashes: as they find it in great abundance, every family is well supplied. They keep it at a small distance from their houses, in earthen vessels, under ground, to prevent any accident by fire, of which it is extremely susceptible.

There is also a white naphtha on the peninsula of Apcheron, of a much thinner consistency; but this is found only in small quantities. The Russians drink it both as a cordial and a medicine, but it does not intoxicate: if taken internally, it is said to be good for the stone, as also for disorders of the breast, and in venereal cases and sore heads; to both the last the Persians are very subject. Externally applied, it is of great use in scorbutic pains, gouts, cramps, &c.; but it must be put to the part affected only: it penetrates instantaneously into the blood, and is apt for a short time to create great pain. It has also the property of spirits of wine, to take out greasy spots in silks or woollens; but the remedy is worse than the disease, for it leaves an amoninable odour. They say it is carried into India as a great rarity; and being prepared as a japan, is the most beautiful and lasting of any that has yet been found. Not far from hence are also springs of hot water; which

boil up in the same manner as the naphtha, and very thick, being impregnated with a blue clay; but it soon clarifies: Bathing in this warm water is found to strengthen and procure a good appetite, especially if a small quantity is also drank." East Long. 59° 2', North Lat. 40° 21'. See Hanway's *Travels*, vol. i. p. 263; Kæmpfer, *Amanitates Exotice*; *Mem. Acad. Berlin*, 1756; and *Decouvertes des Russes*, vol. ii. p. 213. (o)

BALA, a town in the county of Merioneth in North Wales, situated on the east end of a large lake called Bala-Pool, or Pimblemere. The town is clean and pretty large; the single street, of which it consists, is wide, and the houses generally low. A considerable trade is carried on in fruit, stockings, gloves, and flannels. The antiquity of the town is manifest from the remains of three Roman camps, which seem to have been used as exploratory stations before the subjugation of the Ordovices. Bala-Pool is about 1200 yards broad, and four miles long. It produces fine trout, perch, and the gwyniad, an Alpine fish, from one to six pounds weight, which resembles a salmon in shape, and a trout in taste, and dies the moment it is taken out of the water. The river Dee, which runs into the lake, is said to pass through it without mingling its waters with those of the lake. Number of houses, 310. Population, 1463. See Aikin's *Journal of a Tour through North Wales*; and a *Tour in Wales, &c.* in 1805, p. 127, 129, in Philip's *Collection of Voyages, &c.* vol. iv. (o)

BALAAM, a famous prophet, or soothsayer, whose history may be found in the book of Numbers, particularly in the 22d, 23d, 24th, and 31st chapters. Referring to the sacred record, for all the particulars which are known of his life, we shall content ourselves with offering a few observations, with a view to elucidate this curious, but difficult part of scripture history. For this purpose, we shall consider his place of residence, his character, and his conduct.

He is said to have dwelt at Pethor. "Balak sent messengers unto Balaam to Pethor." *Num.* xxii. 5. Now Pethor signifies *to interpret*; and hence it is translated in the Vulgate, *Haribolum*, a soothsayer. The termination in the original, however, evidently denotes locality, and therefore the word is generally understood as pointing out the residence, rather than the designation of Balaam. Pethor is said to be on the other side of the river to the south, beyond the borders of Moab, and seems to agree, both in name and situation, with Petra, in Arabia. There was, probably, a college of priests settled in this place, over which Balaam presided; and from this circumstance it derived its name, signifying literally, *the place of interpretation*. There can be little doubt, that Patara, in Lycia, where there was a famous oracle of Apollo, hence called Patareus, derived its name from the same Hebrew original; and hence also the priests of Apollo, and the interpreters of the oracles, were called Pateræ. *Pateræ sacerdotes Apolloniæ, oraculorum interpretes.* Bochart. *Canaan.* l. 1. c. 40.

As to the character of Balaam, it has been disputed whether he was a prophet, and worshipper of the true God, or merely an uninspired diviner, or soothsayer, who prophesied according to the rules of augury, and vaticination, in use amongst the heathen nations. That he was not of the seed of Abraham, is certain; that he was not a righteous man, is equally certain; but we are not so sure that these circumstances disqualified him from being a real prophet. It is evident that the knowledge of the true God, in these early times, was not

confined to the descendants of Abraham. If the book of Job contains the history of real events, as we are inclined to think it does, it is a proof that God revealed himself to other nations, as well as to the Jews; for neither Job nor his friends were of the family of Israel. Jethro, the priest of Midian, also, had the knowledge of the true God. We need not be surprised, then, that Balaam, who was of the same country, should possess the same knowledge. If holiness be essential to the character of a prophet, Balaam's qualifications must indeed appear very doubtful. But it is evident from scripture, that the persons possessing the prophetic spirit, were not always distinguished by integrity and uprightness. We have a remarkable instance of this, in the conduct of two prophets, as recorded in the 13th chap. of the first book of Kings. Saul himself was, for a time, among the prophets: Caiaphas, the high-priest, who joined in the persecution of our Lord, had a sudden illapse of the prophetic spirit: and some wicked prophets are represented as saying at the day of judgment, "Lord, have we not prophesied in thy name?" Balaam, then, it appears, must be added to the number of those, who have sometimes been favoured with the spirit of prophecy, without always possessing the spirit of holiness.

With regard to his conduct, it does not appear, at first sight, what it was that rendered it so offensive in the sight of God. A little attention to the narrative, however, and to some subsequent intimations of scripture, will enable us sufficiently to explain it. Balak, king of Moab, sent to entreat him, that he would come and curse Israel. Upon this he consulted God, who said, "Thou shalt not go with them." The messengers therefore returned to Balak, who immediately dispatched others more honourable, and empowered them to make him the most flattering offers. Though strongly inclined to comply, yet he did not dare to disobey the positive command of God. He therefore consulted again, and received this instruction: "If the men come to call thee, rise up and go with them." Upon this we are informed, "Balaam rose up in the morning, and saddled his ass, and went with the princes of Midian; and God's anger was kindled because he went." The difficulty which this passage presents, will be solved at once, if we adopt Shucklord's translation: "God's anger was kindled because he went of himself." The meaning then would be, that Balaam had not waited till the princes of Midian called him in the morning, as he had been directed to do, but had abused the conditional permission which God had given him, by officiously offering to accompany them before he had been again solicited. This is the usual explanation of the passage, and may certainly be fairly inferred from the words in which it is expressed; or it may be, that God was offended because he went with a bad intention. That Balaam went with a disposition to curse, rather than to bless the children of Israel, is evident from what the angel says to him, "I went out to withstand thee, because thy way is perverse before me." It appears also, that he industriously sought for evil omens against Israel, and shifted his position several times, that he might, if possible, catch an unfavourable aspect, and pronounce that malediction which the king of Moab so earnestly desired. "But when he saw that it pleased the Lord to bless Israel, he went not, as at other times, to seek for enchantments," *Numb.* xxiv. i. His hostility to Israel is also clearly proved, by the counsel which he

afterwards gave to the Midianites. Finding himself restrained from cursing Israel, he advised the Midianite to seduce them, if possible, into idolatry. This stratagem was but too successful: the Israelites, however, soon returned to the service of God; and, when they avenged themselves on Midian, they slew Balaam with the edge of the sword, as the chief author of their sin and of their calamities, *Numb.* xxxi. 1.

Much has been said on the subject of the ass, and it has often excited the sneers and ridicule of sceptics and unbelievers; but if they had half the sense of Balaam's ass, they would not subject a miraculous event to the ordinary rules of ratiocination. If we admit the possibility of miracles at all, an ass speaking is neither more astonishing, nor less possible, than any other deviation from the laws of nature. Maimonides, however, and almost all the Jewish writers, suppose the whole of this scene to be an allegory, or a vision. Balaam indeed says, that "he saw the vision of the Almighty, falling into a trance, but having his eyes open;" but we cannot be sure that this applies to the particular scene of which we are speaking. St Peter seems to favour the literal interpretation: speaking of Balaam, he says, "the dumb ass, speaking with man's voice, forbade the madness of the prophet;" *2 Pet.* ii. 16. See Shuckford's *Connections*, vol. iii. p. 312. Calmet's *Dictionary*. Bryant's *Mythology*, vol. i. p. 310. Parkhurst's *Lexicon*, on the word *Pethor*. (g)

BALACLAVA, a sea-port town of Tartary, formerly S melon and Cembalo, is situated on the south side of the Crimea. This town appears to have been founded by the Greeks, and afterwards re-peopled by the Genoese; but being deserted by them, and having fallen into ruins, has now reverted to its original inhabitants. The port, which is situated to the west of the town, is about a verst long, and two hundred toises broad, and is sufficiently deep to receive vessels of the largest size. Being protected from every wind by high mountains, the water is always perfectly calm. The entrance to the south is so contracted by high rocks, that it is impossible for two vessels to pass together, without running foul of each other. Dangerous as this entrance appears, the harbour has been gladly made by vessels driven upon the peninsula, which could not double the point of Chersonesus. The port, however, is shut against ships of all nations, from the fear of contraband trade, which, by less cruel means, it would be easy to prevent.

The garrison is ordered to fire upon all vessels, even those belonging to the crown, which attempt to enter the harbour. These severe measures have consequently occasioned a great number of shipwrecks. In the year 1802, no fewer than four ships, in great distress, begged in vain for shelter. They struck opposite the monastery of St George, and the crew and cargo of two of them were entirely lost. The old Genoese fortress is situated at the entrance of the port, upon a high mountain to the east, defended by lofty walls and towers. The town is well peopled, and its position in the centre of the peninsula makes it a place of considerable trade. The population, consisting of Tartars, Greeks, Jews, Russians, and Armenians, amounts to 3000. East Long. 31° 24', North Lat. 44° 38'. See Reuilly's *Travels into the Crimea*, and along the Shores of the Black Sea, in 1803, chap. vi. (x)

BALÆNA, in Zoology, the whale, a genus of mammiferous animals, which in the Linnæan system ranks in the order Cete of the class Mammalia, but in the method

of Ray, and the system of Lacépède, constitutes a tribe of cetaceous fishes. See CEROTOLOGY. (*f*)

BALÆNOPTERA, a subdivision of the whale tribe, formed into a new genus by Lacépède, and including three species, distinguished from the balæna: in having longitudinal folds under the throat and belly, and dorsal fins. See Lacépède, *Histoire Naturelles des Cétacées*, p. 120; and *Dictionnaire des Sciences Naturelles*, tom. iii. p. 442. (*f*)

BALAKLAVA. See BALACLAVA.

BALANCE, the name of a simple machine for ascertaining the weight of any body, or for finding a quantity of any substance equal to a given weight. The balance has generally been arranged among the mechanical powers, but it is evidently only a particular species of the lever in which the two arms are equal, and in which there will be an equilibrium when the power and weight are equal.

The balance consists of a horizontal beam, which turns round an axis or centre of motion exactly in the middle of the beam. The two halves of the beam, on each side of the axis, are called the arms of the balance. From the two extremities of the beam, called the *points of suspension*, are hung two scales, in one of which is placed the substance to be weighed, and in the other are placed weights of a known magnitude. The equality of the weights in the two scales, or the perfect equilibrium of the balance, is known from the horizontal position of the beam. In the common balance, where the whole machine is suspended from the axis of motion, a slender arm, called the tongue of the balance, rises perpendicularly from the centre of the beam, and points to a particular part of the handle by which the whole is suspended when the beam is horizontal.

In balances where very great accuracy is required, the beam is not supported by suspension, but has a fine edge of steel for its axis, which rests upon steel planes. The horizontal position of the beam is in this case determined, by observing when the extremities of the arms point to the zero of two ivory scales fixed in the mahogany frame in which the instrument is placed, the line joining the two zeros having been previously placed in a horizontal position, by levels fixed in the mahogany frame. The beams of these delicate balances sometimes consists of a plain cylindrical rod, of a double cone, whose vertices form the points of suspension, or of a frame in the form of a rhombus.

In constructing an accurate balance, it is necessary, 1. *That the two points of suspension, and the axis or centre of motion, should be in the same straight line.* The energy of any weight in turning a lever round its fulcrum is proportional to the perpendiculars let fall from the fulcrum upon a vertical line passing through the points of suspension. When the points of suspension, therefore, and the centre of motion, are not in one line, the perpendiculars let fall upon the vertical lines are equal only when the line joining the points of suspension is truly horizontal. In every other position, the perpendiculars will be unequal, and there will not be an equilibrium between equal weights. When the points of suspension and the centre of motion, however, lie in the same straight line, the perpendiculars upon the vertical lines must be equal, in every position of the beam, and there will always be an equilibrium between equal weights, the beam being supposed without weight. 2. *The points of suspension must be precisely equidistant from the centre of motion, or; what is the same thing,*

the arms of the balance must be exactly of the same length. It is obvious, that when the arms are unequal there cannot be an equilibrium between equal weights, as the one weight acts at the extremity of a longer lever than the other. 3. *The centre of gravity of the beam should be placed a little below the centre of motion.* If the centre of gravity of the beam coincides with the centre of motion, the beam will rest in any position in which it is placed, whether it is unloaded or loaded with equal weights. If the centre of gravity is above the centre of motion, the beam will be upset by the slightest disturbance. But if the centre of gravity is below the centre of motion, the beam will not rest in any but a horizontal position, and when disturbed will recover this position with a degree of facility proportioned to the distance between the centres of motion and gravity. The nearer, therefore, that the centre of gravity is to the centre of motion, the more easily will the equilibrium be disturbed, and consequently the more delicate will be the balance. 4. *The beam should be as light as possible, but at the same time so strong as not to change its form when the scales are loaded to a maximum.* It is evident, that the friction upon the centre of motion will be diminished by the lightness of the beam, and that the inertia of a light beam will be more easily overcome by a small weight than the inertia of a heavy one.

Having thus stated very briefly the precautions that are necessary in the construction of a delicate balance, we shall proceed to describe three of the best balances that have yet been made. The two first were made by the celebrated Mr Troughton, and the last by Messrs Miller and Adie, mathematical instrument makers, Edinburgh. (*o*)

In Plate LI. Figure 1. AB represents the scale-beam in its most perfect state, as made by Mr Troughton. A strong mahogany box contains the whole; it has drawers below for holding weights, &c.; and a long one behind, wherein the beam is packed, when out of use or in carriage. There are doors in the ends, through which the pans, or scales, are loaded and unloaded, and through another at the top the beam may be taken out. The front and back are of plate glass. On the upper surface of the drawer department are shewn two spirit levels, L, L by means of which, and screws below, the balance is easily adjusted to its due position. There passes through the box, a little below the levels, an iron rod, having at each end a handle, by which it may be turned round. One of these is seen in the figure at H. This rod moves two pinions concentric with itself, and within the box, which act on props, P, P that support the pans, or allow their motion as business may require. A strong brass pillar F occupies the centre of the interior of the box, supporting at top a square platform; on the front and opposite side of this are erected two arches, *m, n* nearly semicircular; and, on their vertices, are fixed two horizontal planes of agate, which afford together the proper fulcrums for the beam. Within the pillar F a cylindrical tube is elevated or depressed by a lever, the handle of which is seen at G between the drawers below: from the upper end of the tube, just above the platform, springs an inverted arch *n*, of as much greater radius than the other two which it crosses at right angles, as brings its span on the outside of them. The beam is formed of two hollow cones of brass joined together by a short cylinder in the middle, and is altogether about 18 inches long. These are formed of a substance not exceeding 0,02 of an inch thick, but, by means of circular rings

driven hard into them at proper intervals, are rendered almost inflexible. The beam is crossed in the middle of its length by a cylinder of steel, the lower diameter of which coincides with its centre. The lower side of this cylinder being reduced to an edge, the angle of which is about 30° , hardened and well polished, forms the principal axis, and rests through a length of about 0,05 of an inch, before and behind, upon the agate planes. Exterior to the parts of action, the axis is worked into two small pivots; and the extreme ends of the inverted arch being formed into angles, the latter when lifted up by the lever below, carries with it the beam, and thus relieves the axis when the instrument is out of use. On lowering the beam, the angles leave the axis in its proper position on the centres of the planes. There being no contrivance to prevent the axis from wandering from the centres of the agates, when this is seen or suspected, the beam must have its position rectified by means of the inverted arch. A weight for adjusting the motion of the beam, respecting the time in which it performs its vibrations, is raised or lowered by a screw at top: its mean position is the centre of the beam. The points of suspension for the scales are both adjustable, the one on the left horizontally, for making the arms of the balance of equal length: the axis is here fixed in a piece which is pushed inwards by a screw, (Plate LI. Fig 2.) while a strong spring of coiled wire, in the inside of the cone, presses it in an opposite direction. The axis on the right is adjustable vertically, for the purpose of bringing the three points of action into a right line: this is brought about by fixing the axis in a sliding piece similar to the other, and it is acted on by two screws which press it in opposite directions. The action at the ends, like that at the centre, is on double bearings; but, instead of by two sharp edges resting upon two planes, is here performed by two concave edges acting at right angles on two other concave edges: the former pair formed in the axis itself being sharp upwards, and the latter pair sharp downwards, formed in the spur shaped pieces from which the scale-strings depend. The ends of the beam terminate in points, and play contiguous to divided ivory scales, which are fixed in the inside of the box: the value of these divisions is indefinite, and varied at pleasure by the adjusting weight: they are, however, of great use in estimating small quantities. For hydrostatical purposes there are only required to be added a common tumbler of water, and a brass wire hooked at both ends. (Plate LI. Fig. 3.) A set of accurately adjusted grain weights usually accompany the instrument; and perhaps, every thing considered, the following series may be as convenient as any:

,001	,01	,1	1	10	100	1000
,002	,02	,2	2	20	200	2000
,004	,04	,4	4	40	400	4000
,008	,08	,8	8	80	800	8000

Greater weights than these might endanger the parts of action.

The following instructions how to adjust this kind of balance may not be unacceptable. 1st, To bring the three points of action into a right line. Without weights, poise the beam by throwing into the scales any bits of light substance, and raise or lower the weight within the beam until the vibrations are thereby rendered very slow; now, put weights into the pans, equal to about half the greatest load you mean your instrument to carry, so that the beam may be poised again: if it now

vibrates slow just as it did before, it proves the adjustment to be perfect; but, in case it either oversets or vibrates too quick, you must restore it to slow motion by the adjusting weight, noting the number of turns of the screw, and parts of a turn, which were required to produce slow motion: now, turn the screw the contrary way, through double the noted quantity, and then produce the required slow motion by the proper adjustment at the right end of the beam. Repeat the operation until the adjustment is perfect. 2d, To make the arms of the beam of an equal length. With weights in the scales as in the last adjustment, poise the beam with the greatest care: now take off the scales by unhooking them, and hang them into contrary ends of the beam, which if now poised, the thing is done; but, if not, take as much hair or wire as when put into the apparently lighter scale, will restore the balance: take away half of it (which is accurately found by doubling and cutting), and poise the beam by the proper adjustment at the left end. Repeat this operation also for greater certainty. The above are the two grand adjustments of the balance: secondary ones, (as poising the beam itself, is done by simply screwing in or out a small screw at the right end; and equalising the pans and hook for weighing in water, which is done by scraping off a little of their substance,) can only require to be enumerated. When the instrument is adjusted in all its parts, the adjusting weight may be moved up or down at pleasure, according as exactness or dispatch may be required.

In Figure 4. of Plate LI. is represented a small beam of the common form, such as is used for assaying of metals, or nice chemical purposes, in which a load greater than 4 ounces is not required. It requires to be inclosed in a glass case, and is supported upon a pillar. A tube inside the pillar is acted on by a lever below, and connected with a square platform and two semicircular arches at top: on the summit of each of these arches is fixed an obtuse angle of hardened steel, which, supporting the very acute angle of the axis, forms the principal part of action. The circular ends of the beam are excavated in the middle of their thickness, on the lower side, a good deal above the centre: the axis is fastened in the two sides of the circular ends, with its sharp edge upwards, a little concave, having passed through a piece of hardened and polished steel of the shape of an 8; the inner edges of the two eyes being worked to sharpness: by the upper eye it hangs upon the axis within the part excavated, forming the point of suspension, and with the lower the scale-strings are connected by a ring. A piece of wire extending above the centre is worked into a screw, and upon this an adjustable ball of brass is placed for the purpose of procuring quick or slow vibrations. Opposite to this, extending downwards, is a long index pointing to a graduated scale of ivory for ascertaining the position of the beam. The lever below is fixed to the pillar, and by its action lowers the beam until the pans rest upon the bottom of the glass case, or raises it when in use. At the top of all there is a light index of brass-wire, which, by being turned round with the finger, serves to adjust the index below to the zero of the ivory scale: this, insignificant as it appears to be, is extremely convenient in practice. This kind of beam is adjusted, respecting equality of length in the arms, by the hammer, and bent by the hand for bringing the three points of action into a right line. (E. T.)

An ingenious balance constructed by Messrs Miller and Adie for Mr Jardine, is represented in Fig. 1. of Plate LII. where AA is the beam forged of one piece of steel, which, in order to give greater strength with lightness, has the form of a rhombus, whose acute angles coincide with the centres of suspension B, B. The ends of the arms pass through the pieces C, C, which are hollow, to receive the two rings D, D, from which the scales are suspended, and terminate in slender points, which serve as indexes to point out the inclination of the balance on the ivory arches EE. The axis or centre of support *f* is about $2\frac{1}{2}$ inches long, 1 inch deep, and three inches thick. Its under edge, worked away to form a right angle, passes through a box *g* in the middle of the beam, and is fixed in its place by 10 small steel screws. The edge of the centre turns on hard and highly polished steel plains *h*, from which it is lifted, when not used by Y's, which are moved up by turning the pinion I, which works in a rack within the hollow brass pillow that forms the stand for supporting the balance. Fig. 2. shews the pieces C, C on a large scale, that the different parts may be more distinctly seen. The rings D, D, which are hardened and well polished, are just allowed to move freely between the four hardened steel points screwed through the sides of the pieces C, C. One of the end centres C is fixed, and the other is made to move in a slit to or from it, by the four adjusting screws *k*. The balance is inclosed in a mahogany case with a glass front, to the back of which is attached the brass frame L, moveable up or down by a rack and pinion M, so as to stop the scales, and thus check the vibration of the balance when in use. The cross levels N on the bottom of the pillar, are intended to adjust the plains on which the centre turns, to a true horizontal position, by means of the four screws O, that form the feet of the mahogany case. In performing the adjustments of the balance, we must begin by placing the edges of the three centres in a straight line as nearly as possible, by pressing down the centre *f* with the two screws *h*, which, if lower than the centres of suspension, will be known by the balance preponderating to either side. In order to adjust the centre of gravity, so as to be just under the centre of support, the rings must be removed from the ends of the beam and the slider *g*, and moved up as long as the beam will librate. When it is too high, either end of the beam on being depressed, will remain in that situation. We must next try if the arms have equal lengths, by replacing the rings and suspending the scales, and then putting equal weights into them. If the balance now remains in equilibrium, the adjustments are complete; but if either side preponderates, that arm is longer than the other, and the moveable centre must be altered accordingly by the screws *k*. The previous adjustments must now be repeated, as every alteration, in a delicate balance, in a greater or lesser degree affects all the others, so that they can only be attained by approximation. A balance of the above construction, which we have tried, was sensible to $\frac{1}{1000}$ of a grain, when loaded with 10,000 grains in each scale. (y)

BALANTES, the name of a tribe of negroes, who inhabit a tract of country about 10 or 12 leagues long, to the north of the isle of Bussi, in West Lon. $17^{\circ} 10'$, and South Lat. $11^{\circ} 45'$. The Balantes have no intercourse whatever with their neighbours. They carry on a considerable trade with the foreigners who enter their roads, in rice, millet, culinary vegetables, oxen, goats, poultry, and particularly gold. The gold, which is of a very superior quality, is supposed to be obtained from mines in the interior of the country. They pay a tribute in gold to the king of Casamanca. In 1696, the Portuguese, joined by 300 Bissaux, attacked the Balantes, but were completely defeated, and lost the whole of their baggage. Several Europeans, who have landed among the Balantes with commercial views, have been plundered and assassinated. See Durand's *Voyage to Senegal*, chap. vi. (j)

BALANUS, in Zoology, a genus of testaceous *mollusca*, in the works of Cuvier, and some other continental naturalists, distinct from the tribe LEPAS, under which they are arranged by Linnæus. See CONCHOLOGY, and MOLLUSCA.

BALASORE HANDKERCHIEFS. A species of the cotton manufacture, in which the Indian fabric is imitated, and the name preserved. To those who are conversant with the general manufacture of muslins, the Balasore handkerchief will present little novelty. The fabric is similar to that of the *Jaconott muslins*, which are of an intermediate degree of closeness between the most dense and the lightest. The border of the handkerchief is formed in general merely by using coarser yarn than the body of the fabric; and this yarn may be so disposed, as to form many different patterns. The texture is merely plain or alternate; and the only additional care, which it is incumbent on the weaver to use, is that of rolling his cloth when finished on the receiving beam. When a piece of these handkerchiefs is newly begun, very little difference of tension will be perceived, but as it proceeds, the difference always increases, and it very soon becomes necessary that it should be counteracted, or the whole fabric would be inevitably injured. The cause of this is the accumulation of the coarser and more bulky material near to each selvage of the cloth. As the coarse warp occupies a greater space than the line, it follows that at every successive convolution, the diameter of the beam must increase in a greater ratio than the former. Again, as the tension of the warp is preserved by the action of the warp and cloth beams in contrary directions, it necessarily follows, that the ratio of tension must depend upon the measure of each diameter; but as by successive

convolutions, the diameter of that part where the borders are wound becomes progressively greater than that which is occupied by the intermediate cloth, the tension of the coarse warp is rapidly increased by the augmentation of the cylindrical measure of the beam. Hence the coarse borders would be burst asunder by excessive tension, before the bosom of the handkerchief had acquired so much as would moderately stretch the warp. To counteract this, layers of paper, or pasteboard, and sometimes small slips or rods of wood, are cut, so as to fill the bosom, and wound upon the beam between the folds of cloth. By the thickness of these being added to that of the cloth, the accumulation upon the beam is kept pretty nearly equal in all parts, and the defect is in a great measure removed. The fabric of the Ballasore handkerchief being nearly the same as the Jaconott, N^o 60, 62, or 64, may be taken as an average set for a 1200 reed, and the different gradations for finer or coarser reeds will be found by the rules laid down in that article. Some allowance, however, must be made for the finer fabrics, or they will appear much more dense than is generally desirable. The reason of this is also pointed out in that article. The difference being merely matter of taste, cannot be exactly specified. By the calculation for a 1500 reed, N^o 100 would be required. Now in common practice, N^o 110 may be considered pretty near the general standard; so that the difference is ten numbers. For a 1000, N^o 45 would be taken by the calculation, and this is very near the usual practice.

In warping the coarse yarn for the borders, different plans are used. It is sometimes warped separately, and beamed at either side of the fine, being crossed over it obliquely before it comes to the rods. At other times, it is warped along with the rest. The coarse yarn is sometimes doubled, to give it a bolder appearance in the cloth, at other times a great number of threads, as four and sometimes six, are crowded into the same interval of the reed. The latter produces much the finest appearance, but is vastly more troublesome to the weaver; for when so many threads are confined in one space, the friction becomes very great during the alternate rising and sinking of the warp; and every small knot or obstruction of any kind, produces much inconvenience both in the warp and woof.

Coloured or dyed yarn is also frequently used for the borders of these handkerchiefs, and may be disposed exactly as the common Balasore borders. In this species, although it is not necessary that the difference of fineness should be so conspicuous as in the white handkerchiefs, where the whole appearance is given by superior density; still the dyed yarn ought to be very considerably bolder than the body of the web, that the colour may appear conspicuously through the intervals of the woof. When coloured borders are composed of single threads of warp, and many threads are crowded together in the same interval of the reed, they appear to very great advantage, because the woof covers so little of the coloured yarn, as hardly to produce any perceptible diminution of the effect; but for the reasons formerly given, they are excessively troublesome to the weaver during the operation. When cords are used, the difficulty is still further increased, although these, when judiciously disposed, greatly heighten the brilliancy and appearance of the border. Balasore handkerchiefs are sometimes checked through the bosom, either with cording or coarse yarn, and the

coloured borders are also frequently checked. These are the only peculiarities of this fabric which, in every other respect, is merely a piece of plain Jaconott muslin. (J. D.)

BALBEC, a town of Syria, celebrated for its magnificent ruins. It is delightfully situated at the foot of Anti-Libanus, in that part of the country commonly called Cælo-Syria. The town is surrounded by a wall, of about four miles in circumference, according to Pococke, and the miserable hovels of the natives form a striking contrast to the venerable remains of ancient architecture. The chief object which arrests attention is, the ruins of the Temple of the Sun, which, even in its present dilapidated state, exhibits the magnificence and grandeur of the original design. The principal doorway has been particularly admired for the beauty of the workmanship. The transverse-stone at the top is adorned with the figure of an eagle, most exquisitely sculptured, holding in his claws a caduceus, and in his beak a large wreath of flowers, which falls down on each side, till it terminates in two genii, or winged figures, which appear as supporters to the eagle. The bird is supposed to be an emblem of the sun, to whom this temple was dedicated; and the two winged figures are supposed to represent the zephyrs, or the air. We must content ourselves with giving a very general account of these interesting ruins, as it will be impossible to render a minute description intelligible, without the assistance of plates. Referring, therefore, the lovers of the arts to Mr Wood's splendid work on *The Ruins of Balbec*, we shall chiefly adopt the account of M. Volney, the latest author who has particularly described these ruins, abridging it as much as is consistent with perspicuity. In entering the principal gate, which faces the mountain on the east, we come into a hexagonal court, which is one hundred and eighty feet in diameter. This is strewn with broken columns, mutilated capitals, and the remains of entablatures and cornices; around it is a row of ruined edifices, which display all the ornaments of the richest architecture. On passing through this court, towards the west, we enter a large square, three hundred and fifty feet wide, and three hundred and thirty-six in length. Along each side of this court, runs a sort of gallery, divided into various compartments, seven of which may be reckoned in each of the principal wings. It is not easy to conceive the use of this part of the structure; but this does not diminish our admiration at the beauty of the pilasters, and the richness of the frieze and entablature. Neither is it possible to avoid remarking the singular effect which results from the mixture of the garlands, the large foliage of the capitals, and the sculpture of wild plants with which they are every where ornamented. At the west end of this court, stand six enormous columns, which appear to be totally unconnected with the rest of the building. On a more attentive examination, however, we discover a series of foundations which seem to mark out the peristyle of a grand temple to which these columns belonged. Pococke supposes that this temple never was finished. We must examine them narrowly before we can conceive all the boldness of the elevation, and the richness of their workmanship. Their shafts are twenty-one feet eight inches in circumference, and fifty-eight feet high, so that the total height, including the entablature, is from seventy-one to seventy-two feet. These six pillars are all that now remain of fifty-four.

The southern side of the grand temple has, at some distant period, been blocked up to build a smaller one, the peristyle and walls of which are still remaining. This temple presents a side of thirteen columns, by eight in front, which, like all the rest of the ruins, are of the Corinthian order: their shafts are fifteen feet eight inches in circumference, and forty-four in height. We can form no idea of the roof which formerly covered this temple, except from the fragments which lie scattered amongst the ruins; these are to be found in the form of lozenges, on which are represented Jupiter seated on his eagle; Leda caressing her swan; Diana with her bow and crescent, &c.

Balbec was visited, in 1751, by Mr Dawkins and Mr Wood, the latter of whom has given a set of most faithful and splendid drawings of the ruins. Mr Bruce also visited Balbec, and made numerous drawings, which he presented to the king, and which he boasts of being the richest offering of the kind ever presented by a subject to his sovereign: if, indeed, they are in the style of Mr Bruce's other drawings, they must be very excellent. A great many plates of the ruins may also be found in Pococke. Several changes have taken place since the journey of Messrs Dawkins and Wood. Such a continual system of barbarous dilapidation is carried on, that perhaps at no very distant period, travellers will be forced to say, *Etiam periere ruinae*. The truth of this observation is confirmed by the words of M. Volney. "They (Dawkins and Wood) found nine large columns standing, and, in 1784, I found but six. They reckoned nine-and-twenty at the lesser temple, but there now remain but twenty. The others have been overthrown by the earthquake of 1759. It has likewise so shaken the walls of the lesser temple, that the stone of the soffit of the gate has slid between the two adjoining ones, and descended eight inches; by which means the body of the bird sculptured on that stone is suspended detached from its wings, and the two garlands which hung from its beak, and terminated in two genii. Nature alone has not effected this devastation: the Turks have had their share in the destruction of the columns. Their motive is to procure the iron cramps, which serve to join the several blocks of which each column is composed. These cramps answer so well the end intended, that several of the columns are not even disjunct in their fall; one among others, as Mr Wood observes, has penetrated a stone of the temple wall without giving way. Nothing can surpass the workmanship of these columns: they are joined without any cement, yet there is not room for the blade of a knife between their interstices. But what occasions more astonishment, is the enormous stones that compose the sloping wall, which surrounds the temple on the west and north. To the west, the second layer is formed of stones which are from twenty-eight to thirty feet long, by about nine in height. Over this layer, at the north-west angle, there are three stones, which alone occupy a space of one hundred and seventy-five feet and a half; viz. the first fifty-eight feet seven inches, the second fifty-eight feet eleven, and the third exactly fifty-eight feet long, and each of these is twelve feet thick. There is still lying in a quarry in the adjacent mountain, a stone, hewn on three sides, which is sixty-nine feet two inches long, twelve feet ten inches broad, and thirteen feet three inches thick.

"When we consider the extraordinary magnificence of the temple of Balbec, we cannot but be astonished at

the silence of the Greek and Roman authors. Mr Wood, who has carefully examined all the ancient writers, has found no mention of it except in a fragment of John of Antioch, who attributes the construction of this edifice to Antoninus Pius. The inscriptions that remain corroborate this opinion, which perfectly accounts for the constant use of the Corinthian order, which was not in general use before the third age of Rome: but we ought by no means to allege as an additional proof, the bird sculptured over the gate; for if his crooked beak, large claws, and the caduceus he bears, give him the appearance of an eagle, the tuft of feathers on his head, like that of certain pigeons, proves that he is not the Roman eagle: besides, the same bird is found in the temple of Palmyra, and is therefore evidently an oriental eagle, consecrated to the sun, who was the divinity adored in both these temples. His worship existed at Balbec, in the most remote antiquity." Mr Wood supposes that Balbec, or rather Balbeth, which signifies in Hebrew, *the city of Baal*, or the sun, had its name from the worship of this deity. It was literally translated *Heliopolis*, or the city of the sun, by the Greeks. There can be no doubt that Balbec is the ancient name, which has again recovered its place after it had been expunged by the Greeks: in the same manner as Tadmor, by which alone Palmyra is known by the Arabs, is undoubtedly the ancient name of that place. The Greeks have confounded both geography and history, by translating the names of places into their own language, instead of giving them their proper unalienable appellations. We know nothing of the state of Balbec in remote antiquity, but as it lies in the road between Tyre and Palmyra, it probably shared the commerce of these opulent cities. It was a garrison town in the time of Augustus; and we read of its garrison being strengthened by the emperor Heraclius, that it might be enabled to withstand the Arabs. On the wall near one of the gates, there is a Latin inscription, in Greek characters, still very legible, viz. *Kenturia prima*, evidently marking it out as a Roman station. When Christianity gained the ascendancy under Constantine, part of the temple was converted into a Christian church, a wall of which is still remaining.

When describing the temple of Palmyra, M. Volney says, "It is a remark worthy the observation of historians, that the front of the portico has twelve pillars, like that of Balbec; but what artists will esteem still more curious is, that these two fronts resemble the gallery of the Louvre, built by Perrault, long before the existence of the drawings which made us acquainted with them; the only difference is, that the columns of the Louvre are double, whereas those of Balbec and Palmyra are detached. The population of Balbec was estimated at five thousand, in 1751; in 1784, it did not exceed twelve hundred." See Volney's *Travels in Egypt and Syria*, vol. ii. Pococke's *Travels*, vol. ii. Wood's *Ruin, of Balbec*. Bruce's *Travels*. introduction. (g)

BALBINUS, one of the Roman emperors. See Crevier's *Hist. Rom. Empire*, vol. viii. p. 382; and Gibbon's *Hist.* chap. 31. (iv)

BALBOA, VASCO NUÑEZ DE, one of the celebrated Spanish adventurers, who, at the beginning of the 16th century, repaired to the New World in search of opulence and fame. He was the first who landed on the continent of South America. He received information that there was a mighty and opulent kingdom situated in the interior, and he transmitted an account of it.

important news to Ferdinand of Spain. The Spanish king, regardless of the claims of Balboa, appointed Pedrarias Davila to supersede him in the government of Darien, and provided him with 1200 soldiers, and a well equipped fleet. No sooner had the new governor assumed his office, than dissensions and sickness conspired to ruin the colony. Balboa sent remonstrances to the court of Madrid, and Ferdinand, sensible of his own imprudence, appointed Balboa lieutenant-governor of the countries in the South Sea. The animosities between Pedrarias and Balboa were now reconciled, and their friendship was cemented in 1515, by the union of Pedrarias's daughter with Balboa. Pedrarias, however, still harboured resentment in his breast; and having arrested Balboa, he accused him of disloyalty to the king, and of a design to revolt against the governor. Balboa was condemned to death, and, in spite of the ardent intercessions of the whole colony, he was executed in 1517, in the 42d year of his age. See Robertson's *Hist. of America*, p. 276. (j)

BALCASH. See **BALKASH.**

BALD EAGLE VALLEY, or *Sinking Spring Valley*, the name of a delightful valley, about 5 miles wide, on the frontiers of Bedford County, in Pennsylvania. Its bottom is limestone; lead ore and slate abound in its vicinity; and it exhibits strong marks of pit-coal. This valley is remarkable for a phenomenon called the swallows, which absorb several of the largest streams, and discharge them again on the surface, after a subterraneous passage of several miles. What are called the "arch springs," is a deep hollow about 30 feet wide, formed in the limestone rock, covered with a stony arch which transmits a fine stream of water. The subterraneous river enters the aperture of an extensive cave about 40 yards wide, in the bottom of which, a strong whirlpool sucks in the floating pieces of timber, and carries them out of sight. In the year 1779, the valley contained about 60 or 70 families, who had formed several valuable plantations. (q)

BALDIVIA. See **VALDIVIA.**

BALDNESS, a disease, or the effect of old age, by which the hair falls from the crown of the head and the parts immediately above the temples. Women and eunuchs are seldom afflicted with this disease, which, in young persons, often arises from excessive venery. See Buffon's *Nat. Hist.* by Smellie, vol. ii. p. 442. (j)

BALDOCK, a neat town of England, in Hertfordshire, built by the knights templars in the reign of Stephen, and standing on a chalky soil between two hills. There is a strange charity in this parish, which is deserving of notice. John Parker, Esq. left 10*l.* a year to purchase 26 penny loaves, to be distributed every Sunday after they had lain on his grave during the time that the bell tolls for the morning service. There are four ancient encampments on the hills in the neighbourhood. The town carries on a considerable trade in malt. Population in 1801, 1283, of whom 202 were employed in trade and manufactures. See Salmon's *History of Hertfordshire*. (w)

BALDWIN, I. and II. emperors of Constantinople, in the 12th and 13th centuries. See Gibbon's *Hist.* chap. 50, 61, vol. xi. p. 169, 232. (w)

BALEARES INSULÆ, the ancient name of the islands of *Majorca* and *Minorca*, off the coast of Spain, opposite the mouth of the Ebro. Of the name of these islands various etymologies have been given; all of them referring, however, to the dexterity in slinging, for

which the inhabitants were particularly celebrated. According to Bochart, the Baleares were peopled by a colony of Phœnicians; and their name is compounded of the two words *בגלל ירה*, *bal-iarah*, signifying *skilful in throwing*. M. Gebelin suggests, that, as *Baal*, the oriental name of the sun, came to be generally applied to all elevated objects, *Baleares* was the proper appellation of those, who were famous for throwing stones from slings to a great height. The more received and proper etymology, however, refers the name of these islands to the Greek word *βαλλειν*, *to throw*. If we may believe the accounts given by ancient historians of the manner in which the Baleares were educated, they could not fail to become the most expert slingers in the world. While yet infants, their breakfast was every morning suspended by their mothers on a tree, nor were they allowed to taste it, till they had struck it down with a stone from a sling. Their dexterity was seconded by great bodily strength, insomuch that the best tempered arms were often shivered by the stones which they discharged. They carried to battle three slings of different lengths, which they used according to their different distances from the enemy.

The Baleares lived for ages in a state of savage simplicity. The skins of sheep, or other animals, served to shelter them from the cold; and caves in the rocks, or holes burrowed out in the ground, were all their abodes. Their fertile soil supplied them with the necessaries of life; nor had they even an idea of its luxuries, till they were corrupted by their connection with the armies of Carthage. Their manners became then so dissolute, and their propensity so lascivious, that, to allure them into foreign armies, no other temptation was necessary than women and wine. Peaceful in their disposition, they lived unmolested by other nations, till some of them having leagued with the pirates who infested the seas, drew upon their country the vengeance of the Romans. About the 630th year of the city, Metellus, the consul, was sent to invade them. He overran their territories without difficulty, and, to secure his conquest, planted two colonies, named Palma and Pollentia, at the east and west extremities of the large island. For his success in this expedition, he was honoured with a triumph, and distinguished by the surname of *Balearicus*. The two islands, of which the larger (now Majorca) was called *Balearis Major*, and the smaller (Minorca) *Balearis Minor*, were about thirty miles distant from each other. They formed a part of the *Provincia Tarragonensis*; and, on account of their excellent harbours, and their commodious situation for navigators in that part of the Mediterranean, obtained the appellation of *Fortunate*. See Campbell's *History of the Balearic Islands*. Grasset St Sauveur, *Voyages aux Iles Baleares*. (u)

BALE. See **BASLE.**

BALI. See **BALLI.**

BALIOI, JOHN, king of Scotland, is remarkable only from his being the successful competitor for the throne of that kingdom, and from his having brought his country to the lowest degree of humiliation. On the death of the Maid of Norway, the nation was distracted by the claims of various competitors for the crown. Bruce and Baliol stood foremost on the list; and, to prevent the civil discord and bloodshed, which must of necessity have ensued from a protracted dispute, they agreed to refer their claims to the arbitration of the king of England. Edward, disappointed in his design upon Scotland,

by the premature death of the Maid of Norway, who had been betrothed to his son Edward prince of Wales, had determined, at every hazard, to gain an ascendancy in that kingdom. A favourable opportunity now offered itself; and his ambition was equalled by his injustice. He summoned the competitors to meet him at Norham, where he had assembled his parliament, and where he proposed to determine their respective rights. But what was the astonishment of the Scottish chiefs, when, instead of deciding their claims with the disinterested integrity of an umpire, he demanded, as a preliminary, that they should acknowledge him as the superior and liege lord of the kingdom. To procure proof, that this superiority had always belonged to the kings of England, he had ransacked the musty chronicles of every abbey in his dominions; and all he could produce consisted of mere fiction and unsupported allegation. But to supply the place of argument, he had assembled a numerous army on the borders, and seemed determined to support the weakness of his proof, by the strength of his power. The love of dominion, and the fear of weakening their cause by offending their umpire, seems to have quenched every spark of patriotism in the breasts of the competitors. None were found daring enough to resist such usurpation; and to the dishonour of our country it is recorded, that they all to a man signed a recognition of Edward's paramount power in Scotland—acknowledging the subjection, and sacrificing the independence of their country. Baliol was chosen by Edward, as the fittest person for assisting him in the prosecution of his ambitious designs. He was crowned at Scone, in 1292, and immediately recognized by the nobility. He then returned to Newcastle, to profess himself a vassal of England, and to do homage for his kingdom. But this was the least part of his humiliation. Edward soon discovered the extent of his ambition. Instead of being contented with the homage of the sovereign, he began to interfere with the internal regulations of the kingdom; and even cited Baliol, upon several trivial occasions, to appear at the bar of an English parliament, to answer as a private delinquent. The king of Scotland bore tamely for a while these grievous indignities; but a train of injuries and insults roused to resistance even the meek spirit of Baliol, who now seemed determined to wash out, by his future conduct, the ignominy of his former meanness and degradation, and to atone to his country for the injustice which he had done her. He openly renounced his allegiance to the king of England, and entered into a treaty with France to make common cause against Edward. But the resolution of the timid Baliol soon vanished in the midst of dangers. An invasion of his dominions compelled him to implore the clemency of Edward, who demanded from him the most abject and mortifying submission. Stripped of his regal ornaments, and mounted on a sorry horse, with a white rod in his hand, he was carried before his conqueror, to whom he acknowledged his deep penitence for the disloyalty of his conduct, and made a solemn and irrevocable resignation of his crown into the hands of Edward. Baliol was sent in chains to remain a prisoner in the Tower of London; but being soon after allowed to retire to France, he resided there, as a private gentleman, on his own estates. During his absence, a band of patriots arose to assert the independence of their country; and though they admitted the name of Baliol into their public acts and manifestoes, they proceeded as if no such person had existed. Some attempts were afterwards

made to restore him to his throne, but in vain. He died in 1314, in the 55th year of his age.

In the character of Baliol there is little either to praise or to blame. His conduct was the effect of a weak rather than of a wicked mind; and he yielded to the circumstances of the times, and to the example of others, rather than to his own ideas of rectitude and honour. He was ashamed of the part he had acted; and his short and unavailing struggle to extricate his country from the power of Edward, entitles him to our commendation and pity. When stripped of his kingdom, he regretted not the power which he had lost, but was contented to live in privacy and retirement in a foreign land. It has been asserted, much to his disadvantage, but upon what authority we know not, that Bruce, his competitor, was offered the crown upon the same terms, and that he generously refused to hold it as depending upon England. From the most authentic records we can affirm, that Bruce was the first who acknowledged the superiority of Edward; that he preferred a petition to him as liege lord of Scotland; and that his son and party were afterwards found under the banners of England, fighting against their country. In contrasting the characters of Bruce and Baliol, with regard to patriotism and integrity of conduct, our preference, however contrary to vulgar opinion, must rest with the latter. See *Biog. Brit. Dalrymple's Annals. Robertson's Hist. of Scotland*, vol. i. p. 10. *Guthrie's Hist. of Scotland*, vol. ii. p. 43—94. *Hume's Hist. of England*, vol. ii. p. 252. (*h*)

BALISTA. See ARMS and ARTILLERY.

BALISTES, in Zoology, a genus of cartilaginous fishes, belonging to the order *Branchiostigi* of the Linnæan system. See ICHTHYOLOGY. (*f*)

BALK, probably the ancient *Bactria*, is a large town of independent Tartary, situated on the river Dehash, which flows into the Amu. It is the capital of the province of Balk, which includes the whole of Great Bucharia, to the south of the Amu. In the beginning of the last century it belonged to the khans of the Usbecks, and was then the largest and the most populous of their cities. The greater part of the buildings are of brick and stone; the fortifications are mounds of earth, supported on the outside with a strong wall; and the castle or palace of the khan is built entirely of marble from the surrounding mountains. In the year 1221, when Zengis Khan plundered this city, and massacred its inhabitants, it is said to have contained 1200 temples, and 200 public baths for foreign merchants and strangers. The inhabitants of Balk were regarded as the most civilized and the most industrious of all the Mahometan Tartars. It is now the chief seat of the trade between Bucharia and Hindostan; and the most beautiful stuffs are made in the town, from the silk collected in the neighbourhood. The fine river of Dehash contributes much to the commercial greatness of Balk. The duty upon merchandise is only 2 per cent.; and those goods which pass through the country, pay no duty. See D'Herbclot, *Bibliothèque Orient.* p. 167. (*g*)

BALKASH, PALCATI, or TENGIS, a large lake in Tartary, belonging to the Kalmucks, subject to China. It is 140 miles long and 70 broad, and is the largest in Asia, excepting Aral and Baikal. (*j*)

BALLANDEN, JOHN. See BELLENDEN.

BALLANDEN, WILLIAM. See BELLENDEN.

BALLAST. See SEAMANSHIP.

BALLI, or BALI, or LITTLE JAVA, one of the Sunda

isles, situated at the eastern extremity of Java. It is about 75 miles long, and 45 wide; and though a great number of the inhabitants are sold for slaves, it contains a population of about 600,000. A great quantity of cotton is produced in the island, which, along with what is brought from Sumbawa, and the neighbouring cities, is made by the inhabitants into different kinds of stuffs.

Rice is produced here in great quantities; but the king does not permit any part of it to be sold. The surplus rice, above what is consumed, is carried annually into the fortresses on the summits of the mountains, for years of war and scarcity. The island produces great quantities of cocoa nuts, oranges, and citrons, with which the woods and uncultivated grounds are filled. The shores of Balli are covered with fish. The only trade which is carried on is in cloths and cotton stuffs, which they transport in their small boats to the coast of Java.

Mines of gold and copper are said to exist in this island; but the king does not allow them to be opened. Balli is an excellent place of refreshment for vessels that go to the Moluccas, to Banda, and to Macassar; and the Chinese sometimes visit it, and exchange their silver and their porcelains for the cotton stuffs of the country. E. Long. 115° 20', S. Lat. 8° 40'. See Peuchet's *Dict. Geograph. Commerç.*; and Forest's *Voyage to Patana*, p. 170. (q)

BALLIBAY, a market town of Ireland, in the county of Monaghan, remarkable for its linen market, and for the extensive bleachfields and mills of Crieve, where 50,000 webs are bleached annually. See Coote's *Statist. Account of Monaghan*. (j)

BALLINA, a town of Ireland, in the county of Moy, beautifully situated on the river Moy. Besides a linen market, it has one of the most considerable salmon fisheries in the island, which produces annually about 80 tons of salted fish, beside those which are sold fresh. See Beaufort's *Memoir*, and Young's *Tour*. (j)

BALLINAHINCH, the name of a barony in the county of Galway, in Ireland. See Beaufort's *Memoir*, Young's *Tour*, and GALWAY. (j)

BALLINASLOE, a thriving and well built town in the county of Galway, in Ireland, remarkable for its great wool fair on the 13th of July, and for several cattle fairs, at which no less than 10,000 oxen and 100,000 sheep are sold annually. See Beaufort's *Memoir* and Young's *Tour*. (j)

BALLINTOY, a small sea-port town of Ireland, in the county of Antrim, with a tolerably good harbour. At a little distance from Ballintoy, the rocky island of *Carrick-a-rede* is separated from the coast by a frightful chasm about 60 feet broad, and of great depth. A narrow pathway, supported by two strong cables, stretches across the chasm. See Hamilton's *Letters on the Coast of Antrim*. (j)

BALLISTA. See BALISTA.

BALLISTIC PENDULUM. See PENDULUM.

BALLOON. See AERONAUTICS.

BALLOTA, a genus of plants of the class Didymia, and order Gymnospermia. See BOTANY. (w)

BALLYCASTLE, a sea-port town of Ireland, in the county of Antrim. In a precipitous bank, which projects into the sea, between Ballycastle and Fairhead, are valuable collieries, which, though still wrought, are not very productive. Various parliamentary grants have been made for making a harbour at Ballycastle; but the pier, which was built to protect it, has been

washed away by the sea, and the harbour choaked up with sand. A vitriolic and a chalybeate spring have been found in the neighbourhood of Ballycastle. See Beaufort's *Memoir*, Hamilton's *Letters on Antrim*, and Ledwith's *Antiquities*. (j)

BALLYMENA, a neat thriving town, consisting of four principal streets, and several smaller ones, is situated nearly in the centre of the county of Antrim, on the banks of a small stream, having its source in the Claggan mountains which lie north of Slemish, and falling into the river Main, two miles west of this town. It contains about 2520 inhabitants, who are mostly presbyterians. The houses are built of stone, and generally slated, forming a striking contrast with some of the other wretched villages in that part of the county.

It consisted originally of a few thatched cabins, but owing to its central situation, and still more to the judicious plan adopted by the present respectable proprietor, Mr Adair, of granting *long leases* to the inhabitants, and otherwise encouraging them to build comfortable houses, it has, in these few years, become a place of some importance, having now one of the greatest weekly markets in Ireland, for the sale of $\frac{2}{3}$ wide brown linens, cows, horses, &c. About two miles distant is the Moravian settlement of Gracchill, a beautiful little village situated on the banks of the Main.

In the streets of Ballymena, a small engagement took place, on Thursday the 7th of June 1798, between a party of yeomanry and a large body of the insurgents, in which the former were defeated and made prisoners; the insurgents kept possession of the town till the Saturday following, by which time their number is said to have amounted to 10,000, and appeared so formidable, that a strong detachment of the king's troops, which lay near Randalstown, did not venture to attack them. They dispersed, however, on Saturday evening quietly to their homes, and, by some previous agreement made with the commanding officer, the town was neither burnt nor pillaged. The new established mail-coach runs through this town from Belfast to Derry. It is twenty-one miles N. W. of Belfast, and ninety-three from Dublin. West Long. 5° 57', North Lat. 54° 55'. (g)

BALLYSHANNON, the principal town of the county of Donnegal in Ireland, remarkable chiefly for a salmon and an eel fishery, both of which are very productive. The salmon leap which is near the town is a ridge of rocks about twelve feet high. Though the harbour is barred, vessels of 40 or 50 tons find a safe anchorage up to the waterfall. See Beaufort's *Memoir*, Young's *Tour*, and M'Farlane's *Statist. Account of Donnegal*. (w)

BALONTES. See BALANTES.

BALSAM, a fragrant, oily, and viscid juice, which exudes from various plants. They are incapable of putrefaction themselves, and have the property of preserving animal substances from putrefaction for a considerable time. See MATERIA MEDICA. (w)

BALSORA. See BASSORA.

BALTIC, or EASTERN SEA, next to the Mediterranean, the most important of the inland seas of Europe. Though it does not appear that the Baltic was ever visited by the Romans, it is mentioned under various names by several of their writers, as a place, of whose existence, at least, they were perfectly aware. It is the Venedicus Sinus of Ptolemy; the Mare Suevicum of Tacitus; and the Sinus Codanus of Pliny.

in the countries which bound it, its ancient name was Variatzkoïé Moré, or the sea of Variaghi. The modern Russians call it Baltiskoé Moré, and the Swedes, Oster Sjow.

The Baltic opens from the German Sea between the 57° and 59° N. Lat. by a gulph pointing north-east, and is there called the Skager Rack; it next passes several degrees south in what is called the Cattegat, to the south-east of which is the sound of Elsinour, a narrow streight between the coast of Sweden and the island of Zealand. This is the general passage for ships going from the North Sea into the Baltic; and a small toll is here paid by way of courtesy to the crown of Denmark, which, in return, erects light-houses, and keeps them in proper repair. After passing Zealand, this sea spreads widely to the north-east, and is at last branched out into the two extensive gulfs of Bothnia and Finland; the former of which stretches north as far as Torneo, within a few degrees of the Arctic circle; the latter extends in a direction almost due east, till it comes within a short distance of the lake Ladoga. Both these gulfs are either covered or much impeded with ice during four or five months of the year. History informs us, indeed, that even the whole of the sea has been, at various times, completely frozen over. In the year 1333, travellers passed on the ice from Lubec to Prussia and Denmark, and tents were erected at certain intervals for their accommodation. The same phenomenon occurred in the years 1399, 1423, 1459, and 1533; in 1709, and 1740, the frosts were also remarkably severe, though the ice was by no means so general or so strong as in the other instances mentioned. These facts serve, with many others, to confirm a favourite theory of modern naturalists, that the rigour of the seasons in the northern countries of Europe, was formerly much greater than at present.

The length of the Baltic from south-west to north-east, is more than 600 miles: it is in general about 75 miles broad, but in some places it spreads to the breadth of 150 miles. Its depth does not exceed fifty fathoms, and it is said to subside at the rate of 45 inches in a century. Mr Otto, however, in his physical observations on the Baltic Sea, has suggested another theory, which is at least plausible, to account for its apparent decrease. He supposes, that instead of really subsiding, it may only be slightly shifting its position, and gaining in one quarter as much as it loses in another. This effect he ascribes to the large rivers, which flowing into this sea with great rapidity, carry along with them vast quantities of earth and sand, by which the beds at their mouths are raised, and their banks extended towards the sea. The waves of the Baltic do not swell so high as in the ocean, but they are more dangerous and harassing to shipping, as they succeed each other with greater rapidity and impetuosity. Amber is deposited in its agitations on the shores of Courland and Prussia; and it appears, that all the knowledge which the Romans possessed of the maritime powers of the Baltic, was obtained by their merchants, who journeyed by land in search of amber. Its water does not contain above one-thirtieth part of salt, whereas the water of other seas often holds one-tenth. This freshness may proceed in part from the number of large rivers which discharge themselves into this sea; but it seems to be chiefly owing to the large quantities of ice formed in its northern gulfs. It has a very perceptible current; and when the wind blows strong from the north, the

water becomes so fresh as to be even fit for drinking or preparing meat. Even in the hottest summers the Baltic is cooler than any other sea. Though it has no regular tides, being almost entirely surrounded by land, yet when a strong west wind prevails for any considerable time, its natural outlet is prevented, and a large accession of water is forced into it from the North Sea; on such occasions, it rises on its coasts a little above its ordinary level. The ebbing and flowing of the German Ocean, though very weak, is said to co-operate with the Baltic, so that traces of their effects may be perceived.

Not fewer than forty streams flow into the Baltic, on this side of the Frozen Ocean, of which the principal are the Düna, the Oder, the Vistula, the Rega, the Persante, and the Niemen. The principal islands in this sea are, Zealand, Rugen, Bornholm, Oland, Gothland, Dago, Cæsel, Cronstadt, Hochland, Tytersaari, Savansaari, Peüsaari, Seitsaari, Mohu, Falster, and Aland. Heavy gales of wind are frequent in the Baltic, particularly in the Gulf of Finland, and it abounds likewise with rocks and shelves, which render its navigation extremely hazardous.

The Baltic washes the coasts of Sweden, Russia, Denmark, Courland, Prussia, and Germany; and the productions of these countries form one of the most important branches of British commerce. The Russian ports in this sea, or more properly in the Gulf of Finland, are Fredericksham and Wyburg, in the government of Wyburg; Petersburg, (or Cronstadt,) the imperial residence, and capital of the government of Petersburg; Narva, Revel, and Hapsal, in the government of Revel, to which Arensburg, in the island of Cæsel, likewise belongs; Pernau, and Riga, in the government of Riga, and in the bay of the same name. During winter, the navigation to these ports is closed, and, as that season approaches, the weather becomes very tempestuous. Revel, Pernau, Arensburg, Hapsal, and Baltic Port, are shut up by the ice in November or December, and are generally open again in February or March. Riga is blocked up in October or November, and opens either in March or April. Narva, Cronstadt, Wyburg, and Fredericksham, shut in October or November, and open in April, though at Petersburgh the ice sometimes continues firm till May. The safest anchoring places are Rogervick Bay, or Baltic Port, Revel Bay, Kasporwich under Hogland island, Aspo, and Sceskar. The coast is rocky and dangerous. All the ports, except Revel, are inconvenient and unsafe for loading and landing goods. By the annexation of Courland to the imperial dominions, Russia gained the ports of Windau and Liebau. Some idea of the Russian trade in the Baltic may be acquired from the following statements of the number of vessels which came to or left its ports, and of the amount of exports and imports in the years 1797 and 1802. In 1797, the number of ships arrived was 2541, of those that sailed 2472,—the amount of imports was 25,592,829*l*.—of exports, 46,940,443*l*. In 1802, there arrived 2768 vessels, and sailed 2632,—the imports amounted to 32,983,418*l*. and the exports to 46,917,131*l*. The customs of the year 1797 amounted to 4,790,807*l*.:—of those in 1802 we have seen no statement. The proportion of British vessels which arrived in these ports in the last mentioned year was 308 laden, and 515 unladen,—there sailed 758 laden, and 39 without cargoes.

Prussia possesses a territory of nearly four hundred

miles on the shore of the Baltic, which, in that extent, receives some of the finest navigable rivers in Europe. There are likewise some branches of the Baltic Sea which indent the Prussian coasts, and are called lakes, or haffs. Of these the largest is the Courish Haff, which runs directly south-west from Memel, spreading to a considerable breadth, and penetrating within sixty miles of Königsburg. The Frische Haff forms a long lake between Königsburg and Elbeng, and communicates with the sea at Pillau. It is also connected with Dantzic by the branches of the Vistula. There is also another haff in Pomerania, formed by the islands of Usedom and Wollin, and communicating with the Baltic by three channels, the principal of which is Swinemunde. The principal Prussian ports on the Baltic are Memel, Pillau, and Dantzic. With these ports Britain carries on a considerable trade. Timber is the chief article of exportation from Memel; corn and timber are the staple articles of the Dantzic trade.

Mecklenburgh, a duchy in the circle of Lower Saxony, lying betwixt the Baltic and the Elbe, has only two ports on the Baltic, Rostoc and Wismar.

Sweden extends along the whole western coast of the

Baltic, on both sides of the gulf of Bothnia, and along part of the northern coast of the Gulf of Finland. It commands, of course, a considerable proportion of the Baltic trade. Its principal ports on that sea, are Stockholm, Gottenburg, and Stralsund.

Though but a small part of the Danish dominions lies upon the Baltic, yet that part is by far the most interesting; and has acquired an importance from the present state of commerce, which it never enjoyed at any former period. The duchies of Holstein and Sleswick, with Zealand, and some smaller islands, nearly shut up the communication between the Baltic Sea and the ocean; and all the trade of Europe passes through that small country.

Copenhagen, the capital of Zealand, and of the Danish dominions, is by far the most considerable port in this interesting territory; and next to it, in importance, is Elsinour, on the Sound. It may be gratifying to our readers, to present them with a Table of the ships of various nations, which have passed the Sound, from the year 1792 till 1805; to which we shall subjoin an average of the principal articles annually exported from all the ports of the Baltic.

Table of Ships of all Nations which passed the Sound in the following Years.

	1792	1793	1794	1795	1796	1797	1798	1799	1800	1801	1802	1803	1804

The following is a pretty correct estimate of the quantity of the principal articles exported from all the ports of the Baltic, to all places; reckoning upon the average betwixt the years 1801 and 1803.

Iron	66,800 tons
Hemp	62,500
Flax	18,700
Tallow	34,800
Grain exported in 1801 and 1802.	
Wheat	994,609 . . . 1,032,941 quarters
Rye	689,133 . . . 1,166,537
Barley	193,046 . . . 194,683
Oats	97,537 . . . 168,201
Pease	32,129 . . . 32,470
Total	2,012,254 . . . 2,594,832

Besides timber in masts, yards, spars, barks, deals, battens, staves, oak plank, and wood of all descriptions;

and many other articles of inferior importance. The number of trading vessels belonging to the states on the Baltic, including those of Norway and Holstein, in 1804, was 4134, carrying about 493,417 British tons. The aggregate value of the exports shipped at all the Baltic ports betwixt the years 1801 and 1803, may be reckoned according to the prime cost price as follows:—

Iron	about 1,002,000 <i>l</i> .
Hemp	2,590,600
Flax	1,028,500
Tallow	2,497,000
Grain	7,608,365
Timber of all sorts	1,589,800
Linens	1,020,000
All other articles	2,186,000

Total 19,522,265

Hence it appears, that in years when there is a great exportation of grain, the aggregate of the Baltic trade may be reckoned to amount to twenty millions sterling. The share which Great Britain has in this trade, leaving the grain out of the calculation, amounts to at least two thirds of the whole; and consists of iron, hemp, flax, and tallow, in a still larger proportion; of wood and timber nearly the whole. Independent of grain, the aggregate trade of this country with the Baltic is twelve millions sterling. See Tooke's *View of the Russian Empire*, vol. i. p. 212. Pinkerton's *Geography*, vol. i. p. 12. Crutwell's *Gazetteer*. Oddy's *European Commerce*. *Physical Observations on the East or Baltic Sea*, by F. W. Otto. *Voyage de deux Français dans le Nord de l'Europe, fait en 1790—1792*, tom. i. p. 354; and Peuchet's *Dict. de la Geograph. Commerç.* tom. ii. p. 535. (μ)

BALTIC PORT, formerly called Rogervyk, one of the five districts of the government of Revel, or Esthonia, in the Russian Empire. It is situated in a bay on the Baltic, in lat. 59° 22', long. 41° 51' 5". (μ)

BALTIC FISHERY. Though the Baltic is not distinguished by any great variety of fish, yet particular species are to be found in considerable quantities along some of its coasts. Of these, the most important are salmon, pike, lampreys, streamlings. The streamlings are a degenerate species of herring, found on all the shores of the Baltic, especially near Pernau, where they are sometimes taken in amazing quantities. The kyllo streamling is a smaller and more delicate variety of that species, quite peculiar to these waters, and is caught in great numbers in the autumnal season near Revel and Baltic Port. When pickled, they make an excellent substitute for sardelles and anchovies. The potted lampreys taken at Narva are equally delicate. See Tooke's *View of the Russian Empire*, vol. iii. p. 168. (μ)

BALTIMORA, a genus of plants of the class Syngenesia, and order Polygamia Necessaria. See **BOTANY**. (τ)

BALTIMORE, one of the eighteen counties of Maryland, in North America, is divided from Ann Arundel county by the river Patapsco, which bounds it on the south and south-west; and from Hartford county by the rivers Gunpowder, and Little Gunpowder, on the east and north-east; its other boundaries are Frederick county on the west and south-west, Pennsylvania on the north, and Chesapeake bay on the south-east. Between the rivers which bound this county, there are two others, called Back and Middle rivers; but they are, properly speaking, only arms of Chesapeake bay. About four or five miles east of the Patapsco, Back river receives two small streams, one of which is called Herring Run. Middle river has scarcely any supply of fresh water. This county abounds with iron ore, of a quality particularly adapted for casting; and the ore is found in banks so near the surface of the earth, that it is never necessary to sink a shaft in order to procure it. The population was estimated about fourteen years ago at 25,434 inhabitants, including 5877 slaves. Annapolis is reckoned its capital, though Baltimore is a far more considerable town. (μ)

BALTIMORE, the principal town in the above county, is the largest in the state of Maryland; and is ranked by Morse the fourth in size, and in commerce the fifth town in the United States. Within these few years, however, it has increased so rapidly, both in trade and population, that Weld, who visited that country in the

years 1795-7, places it next after New-York and Philadelphia; and Du Lac, whose observations were made about seven years ago, rates it one of the most important commercial ports within the extensive countries which the United States comprehend. It is situated on the north side of Patapsco river, at a small distance from its junction with the Chesapeake. The basin, around which the town is built, is reckoned one of the finest harbours in America; and its entrance, scarcely a pistol shot across, is defended by a fort which completely secures it against any naval force. Here the water rises, in ordinary tides, to the height of five or six feet. No situation can be more favourable for commerce than that of Baltimore. Upwards of 2000 merchant vessels can ride in perfect safety within its basin; and the bay, with which it communicates, penetrating two hundred and eighty miles up the country, and connected besides with many noble rivers, affords uncommon facilities for inland navigation. A creek divides Baltimore into two parts, one of them what is properly called the town, and the other Fell's Point. As the water in the harbour is only nine feet deep, and a particular wind is necessary to enable ships to get out, the greater number of those which trade to Baltimore stop at Fell's Point, where vessels of six hundred tons burden can lie without danger. These advantages have induced many of the mercantile people to settle on this point, which is connected with the town by two bridges built over the creek. Houses extend irregularly between them; and upwards of seven hundred have already been built upon the point, and a plan for regular streets, and a large market-place, has been laid down, and partly executed. In the town itself, the principal street, named Market Street, runs nearly east and west, parallel with the water, and is at least a mile in length, and about eighty feet wide. Here, as in Philadelphia, most of the streets cross each other at right angles, and several of them, particularly Calvert, South, and Gay Streets, are handsome and well built. Some of the rest, however, are not paved, so that when heavy rains fall, the soil, which is a stiff yellow clay, retains the water long, and renders them almost impassable. Baltimore contains ten churches; and the various denominations of Christians are, Episcopalians, Presbyterians, German Lutherans, German Calvinists, Reformed Germans, Nicolites or New Quakers, Baptists, Roman Catholics, and Methodists. Each of these sects have one church, except the Methodists, who have two. The Presbyterian church is the finest building in the whole town. It is built of brick, with a large portico in front, supported by six pillars of stone. The court of justice, the customhouse, and the guild-hall, are also very fine edifices. Here, as at Philadelphia, there are an hospital and poor house, a prison, theatre, and a bank, which, when Du Lac visited the town, was unfinished.

The low situation of the town renders it rather unhealthy, though its rapid increase has given rise to improvements which have considerably meliorated the air. Here, as well as in New York and Philadelphia, the yellow fever has sometimes committed its ravages. The most sickly season is in autumn, when the wealthy inhabitants generally retire to their country seats, many of which are situated most delightfully in the neighbourhood of the town. To the north and east the land rises, and affords a most enchanting landscape. "The town," says Morse, "the point, the shipping both in the basin and at Fell's Point, the bay as far as the eye

can reach, rising ground on the right and left of the harbour, a grove of trees on the declivity at the right, a stream of water breaking over the rocks at the foot of the hill on the left, all conspire to complete the beauty and grandeur of the prospect."

Baltimore is inhabited by people from all the various parts of Europe, of whom the Irish are the most numerous. Almost the whole inhabitants are engaged in trade, to which they very diligently apply. Their character is very superior to that of the Americans in general; and their hospitality to strangers has drawn forth the warm eulogiums both of Du Lac and Weld. We cannot deny ourselves the pleasure of quoting a compliment paid by the former of these travellers to our countrymen who have settled in Baltimore. "The principal commercial houses in Baltimore," says he, "are Scotch. This active, enterprising, economical, and industrious people, carry with them the love of labour and the arts."

To obtain some idea of the increasing prosperity of this place, we need only compare its present population with the statements given of it at various periods within the last eighteen years. In Morse's American Geography, published about the year 1790, he states the number of inhabitants to be between 10 and 11,000. In his Gazetteer published in 1797, he informs us, that in 1791 the population amounted to 13,503, but that the number of inhabitants and houses had since been greatly increased. Weld supposes the population to have been 16,000; and Du Lac about eight years after found it amounted to 30,000. The exports in the months of July, August, and September, of the year 1790, amounted to 343,584 dollars; in the same months of 1795, they were not less than 1,675,748 dollars. The business of the town is managed by a board of town commissioners, a board of special commissioners, and a board of wardens; the first board is perpetual, and fills its own vacancies; the other two are appointed by electors, chosen by the citizens once in five years. N. Lat. 39° 21', W. Long. 77° 48'. See Morse's *Geog.* p. 353. Morse's *Gazetteer*. Weld's *Travels in North America*, p. 25. Du Lac's *Travels, in Philips' Modern Voyages and Travels*, vol. vi. p. 24. (u)

BALUCLAVO. See BALACLAVA.

BALZA, or BALZE, in navigation. This is a singular kind of vessel, or rather raft, which is used chiefly in South America, constructed simply by the union of logs of wood; but which, nevertheless, is rigged somewhat like a sloop or schooner. The mode of steering this vessel is said to be the origin of the sliding keels lately adapted to some vessels of the British navy.

According to Don Antonio de Ulloa, and Don George Juan, the balza is also called Jangada. It is employed for transporting goods, and for fishing in the river Guayquil, and the South Americans navigate the coast in it. In structure, it consists of several large logs, twelve or thirteen fathoms in length, lashed together by strong ropes, and secured to cross pieces at each end. The logs are commonly nine in number, and so large, that the breadth of the whole is between 20 and 24 feet. Some balzas have one mast and a small foresail; but others, described by Joris Spilbergen, have two with large triangular sails.

The greatest peculiarity of the balza consists in its sailing, and working as well against the wind, as vessels which have keels. This is said to be effected by

the mode of steering it, which is done by means of a device quite different from the rudder. Planks, three or four ells in length, and half an ell in breadth, called *guares*, are disposed vertically, both in the fore and after part of the balza, between the beams of which it is composed. By lowering some of these planks in the water, and raising others, the balza is guided in whatever course is required. "Were such an invention known in Europe," Ulloa observes, "disastrous shipwrecks would be more unusual."

Don George Juan has made some observations on the use of the guares, wherein he endeavours to demonstrate, from mechanical principles, that depressing the guare, near the prow of a vessel, will bring her nearer the wind, and elevating it will make her fall off. Sometimes four, five, or even six guares are employed at once to prevent the balza from making lee-way. The management of the guares is so easy, that after the balza gets under way, merely raising or depressing them one or two feet will steer it right forward.

Probably the balza was known to the ancients under the name of *ferula*. Columella speaks of it, and also Pliny, who remarks, that there were two kinds used by the Greeks. See Ulloa and Juan, *Relation del Voyage a la America Meridionale*, vol. i. Spilbergen's *Voyage round the World in 1615*. Sir Richard Hawkins' *Voyage*. Burney's *Voyages*, vol. i. Columella, lib. 5. Pliny, lib. 13. (c)

BAMBA, the largest province of the kingdom of Congo, in the west of Africa, situated between the rivers Lose and Ambrisi. The soil is very fertile and productive, and the mountainous regions are said to contain mines of gold and silver, copper, quicksilver, tin, and iron. The fishing of the zimbis, the shell of which is the current coin of the kingdom, and in all the neighbouring states, is a great source of revenue. A great quantity of salt is produced on the coast, and exported to the neighbouring states. See Cavazzi *Relation Historique de l'Ethiopie Occidentale*, translated by Father Labat. (q)

BAMBARA, a kingdom of Western Africa, traversed by the river Jolibah or Niger. According to Mr Park, the language of Bambara is a species of corrupted Mandingo. The country is beautiful and well cultivated, and at Kabba, near Sego, the capital of the kingdom, it was not unlike the central districts of England. The inland commerce consists chiefly of the shea-trees, from which the inhabitants prepare their vegetable butter. Strangers seem, from the relation of Mr Park, to be treated with great humanity and kindness; and the Dooty, or chief man in the town through which he passed, appeared to consider it as a part of his duty to feed and succour all travellers in distress. See Park's *Travels*. (j)

BAMBERG, formerly called BABENBERG and PFAFFENBERG, the capital of the ancient bishoprick of Bamberg, and now the chief place of the two bailliages of Bamberg, in the circle of the Mein, in the new kingdom of Bavaria. It is situated on the Rednitz and the Mein, in a fertile country, which abounds in esculent herbs, fruits, grain, and wine; but it is most remarkable for the fine liquorice which it produces, and exports to different parts of Europe. The plant takes very deep root, and rises to the height of five or six feet. Saffron is also produced here, but it is inferior to that of Austria. Bamberg is a great thoroughfare. Its streets are

wide, its buildings neat and regular, and its public edifices remarkably magnificent. The cathedral, which is a very splendid building, contains the tombs and the imperial crowns of Henry II., and his empress Cunigunda. This royal pair declared on their deathbed, and ordered it to be inscribed on their tombs, that both of them lived and died virgins. The new palace of the bishop, the town-house, the orangery, the new hospital, and the Benedictine convent, are objects worthy of the notice of strangers. There are two great fairs in Bamberg, one in spring and the other in autumn; and it carries on a considerable trade with Francfort and Nuremberg, in wine, grain, fruits, saffron, and liquorice. Population 19,385. East Long. 10° 51', North Lat. 49° 56'. See Keyser's *Travels*, vol. iv. p. 549. *Merkwürdigkeiten der Stadt Bamberg*, vom H. v. Murr. Bamberg, 1799; and Reichard's *Guide des Voyageurs en Europe*, tom. ii. p. 38. (o)

BAMBOO HABIT, a contrivance among the Chinese for keeping themselves afloat in water, by a number of cross bamboos. (j)

BAMBOUK, or **BAMBUCK**, a kingdom of western Africa, situated between the rivers Baſing and Faleme. The soil of this state is dry and unproductive, the temperature extremely high, and the climate unwholesome. Gold is so plentiful, that it is obtained by merely scraping the surface of the earth, which is clayish and sandy. When the mine is rich, it is wrought only to the depth of a few feet. In separating the gold from the earth, the larger pieces only are obtained, as the lesser pieces are washed away with the water which runs down an inclined plane. According to the Abbe Demanet, there are also mines of silver, lead, and tin. The iron, which they melt and convert into instruments of husbandry and war, is of a very excellent quality, and saltpetre is found in great quantities.

The inhabitants of Bambouk have woolly hair and a sable complexion. They are distinguished into two sects, viz. Mahometans and Deists, but they live in harmony and mutual toleration. Their food is rice, beef, and mutton, and their wine is a liquor prepared from fermented honey. The method by which they weave their cotton cloths, is very laborious and difficult. The kingdom is traversed by the mountains of Konkodoo, which abound with gold. Bambouk, the capital, is situated on a stream which runs into the river Faleme. See Raynal's *Hist. of the East and West Indies*, vol. iv. p. 138; and Rennel's *Proceedings of the African Association*, 1778. (w)

BAMBUSA, a genus of plants of the class Hexandria, and order Monogynia. See **BOTANY**. (w)

BAMFF. See **BANFF**.

BAMIYAN, or **BAMIAN**, a city placed in the centre of Paripamisus, a branch of Mount Caucasus, in that part of independent Tartary called Great Bucharía. In Sanscrit it is called *Vámi-nagari*, *Vámi-grám*, and in a derivative form *Vámi-yán*, "the most beautiful and excellent city." It is a place of great antiquity, and at a very early period was regarded as the metropolis of the sect of **BUDDHA**. It was therefore emphatically styled *Buddha-Bámiyan*; but this venerable title has been perverted by the malicious Mussulmans into *But-Bamiyan*, or *Bámian*, "of the evil spirit."

This celebrated city, the Thebes of the east, is represented in the books of the Buddhists, as the source of purity and holiness. They pretend that it was built

by the patriarch Shem, from whom it is sometimes called *Sham-Bámiyan*. This patriarch they suppose to have been an incarnation of **JINA** or **VISHNU**; an opinion which likewise prevails among the Bramins.

Bámiyan is situated between Bahlac and Cábúl, from the latter of which it is distant eight *manzels* or days' journey. Like Thebes in Egypt, it is entirely cut out of an insulated mountain; and the surrounding valley is called, in the language of the country, the *Tágávi*, or district of Bámiyan. About two miles south from this place are the ruins of an ancient city called *Gulghuleh*, which, at a remote period, was desolated by the furious zeal of the Musulmans. The ruins of some buildings of masonry are still seen round a small conical hill in the neighbourhood, whose summit is crowned with the ruined palace of its ancient kings. Through the ruins of Gulghuleh, and the district of Bámiyan, flows a pleasant though scanty stream, which rises in the adjacent hills, and falls into a lake, from which issue four rivers, the Hirمند, the Landhi Sindh, the rivers of Bahlac, and of Conduz.

The city of Bámiyan consists of a great number of apartments and recesses cut out of the rock; and from the *Ayeen Akberry*, as well as from the concurring reports of travellers, we learn, that there are about 12,000 of these recesses in the *Tágávi* of Bámiyan. Some of these appear, from their extraordinary dimensions, to have been designed for temples. None of them have pillars, but some are adorned with niches and carved work; and fragments still remain of figures in relief, which have been miserably mutilated and defaced by the Musulmans. The walls, too, have been decorated with paintings, the colours of which gleam, here and there, through the smoke with which they have been in general obscured by the fires of the inhabitants. These recesses are called by the natives *Sumach'h*, and by the Persians *Samaç*. They are very frequent in the country of the Afghans; some of them extremely rude, but others highly finished and beautifully decorated. The most perfect are at Mohi, on the road between Bámiyan and Bahlac, in which the paintings retain their original freshness, as their situation amongst precipices has prevented the Musulmans from making them their habitations.

But no curiosities in Bámiyan or its vicinity are more calculated to attract attention, than two colossal statues seen at a great distance, which are at least fifty cubits high. They adhere to the mountain out of which they are cut; and stand erect in a sort of niches, the depth of which is equal to the thickness of the statue. At a small distance from these stands another statue of less colossal size, being only about fifteen cubits high. Concerning the names or sex of these statues, oriental writers are not agreed. The few Hindus resident in these countries say, that they represent **BRHM** and his consort; while the followers of Buddha maintain, that they are the statues of **SHAHAMA**, and his disciple **SALSALA**. The Musulmans, on their part, contend, that they are the effigies of Key-Umursh and his consort, that is to say, Adam and Eve; and that the third represents Selish or Seth, their son, whose tomb, or at least the place where it stood, is shown near Bahlac. As the Musulman troops never pass that way without firing a few shots of cannon at them, one of the legs of the male figure is much broken. It is said that Aureng-zebe, passing that way in his expedition to Bahlac, in the

year 1646, ordered a few shots to be fired as usual. One of them took effect, and almost broke the leg of the statue, which bled profusely. Some frightful dreams conspired with this prodigy, to make him desist from the sacrilegious attack, and the clotted blood, we are told, adheres to the wound to this day. This miracle is equally credited by Hindus and Musulmans; the former ascribing it to the interposition of the Supreme Being, and the latter imputing it to witchcraft. Between the legs of the largest figure there is a door leading into a most spacious temple, at the entrance of which are stationed a few wretched Banians who sell provisions to travellers.

Bámíyan and Bahlac are constantly confounded by Persian authors, who call the first Balk-Bámíyan, and the second Bálk-Bóhárá. These authors suppose it to have existed before the flood; but the Buddhists maintain that it was founded by a most religious man named Shama, (the same with the patriarch Shem) and that his posterity lived there for many generations. They add, that Bálk-Bámíyan was originally Abraham's place of abode; that patriarch, according to scripture, and the sacred books of the Hindus, having removed with his father to distant countries in the west. Diodorus Siculus informs us, that it existed before the time of Ninus; but he, like the Persian writers, has mistaken this city for Bahlac. By the natives, Bámíyan and the adjacent countries are regarded as the abode of the progenitors of the human race. Here, too, the first heroes of Persian story lived and performed innumerable exploits; here their holy instructors first delivered their precepts: and here was the scite of the first temples that were ever reared.

Bámíyan fell into the hands of the Musulmans at a very early period of their history. At one time it was governed by kings; but this dynasty, after continuing but a few years, terminated in 1215. Gulghuleh, the royal residence, called then the palace of Bamian, was destroyed by Zengis Khan, whose resentment against the inhabitants was so violent, that he massacred them without distinction of age or sex, and even vented his fury against the brutes and trees. The natives of that country gave it then the name of Gulghuleh, signifying, "cries of woe." As it would have been ominous to rebuild it, they erected in its stead a fort, on a hill to the north of Bamians, which still bears the name of Imperial Fort. This castle also was destroyed by Zingis the Ushak, in 1628, and has never since been rebuilt.

The district of Bámíyan is now barren, and without a single tree; yet the sacred books of the Hindus, and of the Bauddhists, positively affirm, that of old it was fertile. There is a tradition, too, that at one period it was so overstocked with inhabitants, that trees, underwood, grass, and plants, were all completely destroyed. The vegetable soil, thus deprived of cultivation, was, in the course of ages, washed away by the rains; and indeed the soil in the valley is extremely rich, and the whole district, as it now is, a most delightful spot. The vine, and almost all the fruit trees we have in Europe, grow spontaneously and to high perfection in the country to the eastward of Bámíyan, as far as the river Indus. The natives, when they find a vine or any fruit tree in the forests, clear away all the wood about it, and dig the ground, which brings the fruit to perfect maturity. Bámíyan seems to be the Drastoca of Ptolemy, that name being derived from the Sanscrit Drashateá, which sig-

nifies the "stone city;" for before that time towns were nothing more than a mere assemblage of huts. The distance and bearing of Drastoca from Cabura, or Orthospana, leaves no doubt that it was the same city as Bámíyan. For the whole of our information concerning this city, we are indebted to Captain Francis Millord's ingenious *Observations on Mount Caucasus*, in the 6th volume of the *Asiatic Researches*, p. 462, &c. (μ)

BAMPTON, a market town in Devonshire, is situated on a branch of the river Exe, and surrounded with lime-stone hills. The principal manufacture of the place is serges. Population 1364. See Plot's *Natural History of Oxfordshire*; and Polywhele's *History of Devonshire*, vol. ii. (j)

BANANA. See PINE APPLE.

BANARA, a genus of plants of the class Dodecandria, and order Monogynia. See BOTANY. (ω)

BANBURY, a town of England, in the county of Oxford, situated on the river Charwell. From the number of Roman coins, &c. found in the adjacent fields, it is supposed to be the scite of the Roman station Branavis. The canal from Oxford to Coventry passes through Banbury. There is here a manufactory of plush and shag cloths; and two springs, one sulphuretted, and the other chalybeate. Population 2755, of whom 567 are employed in trade and manufactures. See Bray's *Tour in Derbyshire*. (j)

BANCA, one of the Asiatic islands, situated between Sumatra and Borneo, and separated from the former by the straits of Banca. The king of Banca, who resides in the territory of Palambang, in the isle of Sumatra, is in alliance with the Dutch, who have a settlement and troops at Palambang. The Dutch assist him in maintaining his independence, and are amply repaid by the monopoly of the tin, for which the island of Banca is so celebrated. The tin mines, which appear to be inexhaustible, were discovered in 1710. The managers of the mines, who happen to be Chinese, deliver the tin to the king for 5 rix dollars per 125 pounds; and the Dutch obtain the same quantity for 15 rix dollars, which is nearly 2*l.* 18*s.* per English cwt. The quantity received by the Dutch, amounts to about three million of pounds annually, the greater part of which goes to China. In 1778, 700,000 pounds were sent to Holland. East Long. 106° 30', South Lat. 2° 30'. See Wilcocke's edition of Stavorinus's *Voyage to the East Indies*, vol. i. p. 557. Staunton's *Embassy to China*, vol. i. p. 505; and Marchand's *Voyages*, vol. i. p. 98. (ν)

BANCALIS, a town in the kingdom of Acheen, in the island of Sumatra. See Peuchet's *Dict. de la Géographie, Commerc.* and ACHEEN. (ω)

BANCHUS, in Zoology, a genus of hymenopterous insects in the system of Cuvier and Dumeril, belonging to the family of *insectirodes*, and nearly allied to the *ichneumon*s. See ENTOMOLOGY. (f)

BANDA ISLES, the name of a group of Asiatic islands, called the Spice or Nutmeg islands, lying to the south of the island of Ceram, and to the south-west of Papua, or New Guinea. The islands comprehended under this general name are, Banda or Lantor, Neira or Nera, Puloway, or Way, or Ay, Pulo-rohn or Rohn, Rossingen or Rossagay, Gonong or Guenanape, or Ganapez, Pulo-pisang, Pulo-prampon, Pulo-suanjee Capal, and Nylacky.

In the year 1602, the Dutch landed in the Banda

isles, which formed one of their earliest settlements in the Indies. In 1609, they entered into a treaty with the Orançais or natives, who bound themselves to send all their nutmeg and mace to the Dutch fort of Nassau, in the island of Nera, at a fixed price, while the Dutch pledged themselves to defend the natives, particularly against the Portuguese. The breach of this agreement by the natives, and the murder of the Dutch commissary, occasioned hostilities between the two powers. In 1616, a similar treaty was entered into with the English, who were then at war with the Dutch; but this also was broken by the inhabitants of Banda. The English having refused, after they had made peace with the Dutch, to join them in the reduction of the Banda isles, the latter attacked them in 1621, and compelled the natives to deliver up their towns, their forts, their arms, and all their islands. In order to secure to themselves the nutmeg and mace which these islands produced, the Dutch erected forts in all the islands, and divided the soil into orchards, which they distributed among the Dutch colonists in proportion to the number of their slaves. The Banda isles were taken from the Dutch by the English admiral Rainier in 1796, and in 1801 were restored to them by the treaty of Amiens.

The chief settlement of the Dutch is in the island of Nera, which has an excellent harbour, commanded by the cannon of the forts Belgica and Nassau. The island of Banda, which is about 8 miles long and 5 broad, is defended by a fort and two or three redoubts. It contains 25 nutmeg fields, which produce annually about 570,000 pounds of nutmegs, and 140,000 pounds of mace, called the flour of nutmeg. The hurricane of 1778, however, nearly annihilated the nutmeg trees of this island. These nutmeg fields occupy about 70,000 square toises. In the island of Puloway there is a small fort; Pulo-rohn is defended by a small redoubt; Rossingen has also a redoubt; and Gonong is remarkable for a volcano, which always sends forth smoke, and sometimes flames. The nutmeg flourishes amidst the lava of Gonong, as well as in the fine black mould which covers the other islands.

In the year 1796, the annual produce of the Banda islands was 163,000 pounds of nutmeg, and 46,000 pounds of mace. Between the years 1796 and 1798, the English East India Company imported 817,312 pounds of cloves, 93,732 pounds of nutmegs, and 46,730 pounds of mace, and about a third part more in private trade. In the year 1737, the Dutch East India Company sold at one time 280,964 pounds of nutmeg. In 1756, 241,427 pounds were sold; and in 1778, 264,189 pounds. The average has been considered to be about 250,000 pounds annually, which was sold in Europe at 75 livres per pound, exclusive of 100,000 pounds sold in the Indies. The average quantity of mace has been 90,000 pounds annually, and 10,000 pounds in the East Indies.

While the Banda isles supply Europe with their spices, they deny the means of subsistence to their own inhabitants. Sago, which is the pith of a tree of moderate size, serves them for bread; and the juice which exudes from its branches is their ordinary beverage. The cattle and grain which they use are imported from the island of Java. The population of these islands, which is said to have been once 15,000, is now only 5763. E. Long. 130° 40', S. Lat. 4° 18'. See Stavortinus's *Voyage by Wilcocke*, vol. i. p. 331, vol. ii. p. 418. Bougainville *Voyage Autour du Monde*. Raynal's *Hist.*

of the Indies. Asiatic Register, 1800, p. 200; and Pouchet's *Dict. de la Geog. Commerç.* (4)

BANDAGE. See SURGERY.

BANDANA HANDKERCHIEFS, a species of the East Indian manufacture much admired in Europe, and fabricated in India both from silk and cotton. The ground of these handkerchiefs is commonly of a dark colour, most frequently red, blue, or purple; and the pattern almost always consists of spots generally white, or sometimes a bright yellow. The durability of the colours, and the darkness of the ground, have contributed to cause a very great demand for this article in the European market; and, from this cause, the home manufacturers have been long very anxious to produce articles of this description, which might rival the Indian goods in quality and cheapness.

The only mode of accomplishing this, was for a long time, and until very recently, considered to be by the ordinary process of calico printing with blocks upon white cloths; but in this way it was very rarely, if ever, in the power of the manufacturer to render his colours sufficiently durable, especially the reds; and therefore the home made article was never held in estimation by purchasers, most of whom consisted of that class of people to whom durability was a most essential, and even indispensable, requisite. Besides the difficulty of fixing the colour sufficiently, the tax upon this, as well as every other species of printed cloths, must have operated considerably in the comparison with the imported goods. Lately, however, a discovery has been made of a mode of manufacturing this kind of handkerchief, so as to ensure the durability of the colour, and at the same time to be entirely free from any tax whatever under the existing revenue laws. This manufacture was first practised at Glasgow, where it is now prosecuted to very considerable extent; and it is still, we have reason to believe, entirely confined to that part of the country.

The new process is exactly the converse of printing; for it consists of dyeing the cloth of a durable colour, as red, blue, or purple, and then discharging that part which forms the pattern, by means of a strong solution of the oxy-muriate of lime applied by a mechanical process, which we shall now describe, referring the reader for a plan and section of the apparatus used, to Plate LII. Figs. 3. and 4.

The goods used for this manufacture are of cotton, sometimes woven plain, but much more frequently tweeled. The cloth after being woven, is dyed, and the colour most frequently used is the Turkey red. After the cloth has been dyed, it is smoothly and regularly folded in pieces generally containing twelve handkerchiefs each, and in this state is put into the press; which being firmly shut, to prevent the discharging liquor from coming into contact with, or operating upon, any part of the cloth, excepting that from which the colour is to be extracted, in about ten or twelve minutes the chemical discharge is completed. As soon as this is done, the press being opened, another piece is put in, and the operation repeated; so that, allowing 15 minutes for each piece, about 50 may be put through the press in the course of a day of 12 working hours, by the labour of one man, if the pieces be previously folded, which is generally the case. The pieces, after discharging the red, require only a little cleaning, by the usual processes for coloured goods, when they may

be returned to the warehouse, or sent to the callender to be folded and dressed for the market.

Representations of the press used for this purpose, will be found in Plate LII. Figs. 3. and 4. Fig. 3. is a horizontal plan of the bottom or under part of a press constructed for manufacturing Bandana handkerchiefs, of the pattern represented in the figure. Fig. 4. is an elevated section of the press, as seen from the front. In presses of this kind, the chief requisite is great strength, and for this reason the frame work is commonly made of cast iron. Wherever a spot is to be made, the smooth copper plate CC, which forms the under part or sole of the press, is perforated, and in the upper part is a hollow metal dye or tube, commonly made of brass, which exactly fits the hole below. The cloth being smoothly folded in squares, the piece, which generally consists of twelve handkerchiefs, is laid in the press, and the press firmly shut by means of the screw D; when this is done, the liquor being poured upon the cover B, which has a rim about half an inch deep to prevent it from running off, passes down through the perforated tubes or pipes, and in a few minutes discharges the colour from that part of the cloth through which it passes, and thus the spots are formed. Under the sole of the press, another flat piece with rims is placed to receive the liquor, which is conveyed by a small spout into a vessel placed to receive it; as even after effecting the discharge of the colour, it is of considerable value for other operations of bleaching. AA represents the frame, BB the cover, CC the sole, D the double threaded screw, and E a strong malleable iron wheel for receiving the lever with which the press is shut.

The mode of pressing by water, which will be found particularly described under the article CALLENDER, is peculiarly well adapted for this operation, and every other where the press requires to be frequently opened and shut. A plan is therefore added, by which the pressure may be effected on a principle nearly similar. In this plan the pressure is produced by the piston G (Plate LII. Fig. 4. working in a smoothly bored hollow cylinder F, attached to the sole of the press: H is the pipe which contains the water, which passing through the piston at G, forces up the sole of the press and the cylinder F. The dark shade shows that part of the pipe which is filled with water, the right hand stop-cock I being open, and the left hand cock at K shut. The press will be instantaneously opened, merely by shutting the cock at I, and opening that at K to discharge the water: and as the pipe may be of a very small bore, very little water will be lost at each operation, no more being discharged than that contained between the stop-cocks. It seems very obvious, that where it may be inconvenient to have a pipe of sufficient altitude to give the proper pressure, steam might be very easily introduced in the place of water, and would, at a very small expence of fuel, effect the pressing operation with very great power. This hint may, perhaps, be useful; but we are not aware that it has in any instance been hitherto attempted. In large works, where there is a steam engine employed for other purposes, it seems however to be worthy of consideration, being probably a more direct and economical way of attaining the end than by forcing water to the altitude required.

The chemical substance employed in the operation of discharging the colour, has already been stated to be the oxy-muriate of lime, which, we believe, is only prepared

in Scotland by the inventor, Mr Tennant of Glasgow. (J. D.)

BANDITTI,* from the Italian *bandito*, persons outlawed. This term being in Italy almost wholly appropriated to those troops of ruffians who infest the highways, and, forming a distinct society of themselves, set the laws of their country at defiance, has become the general appellation of all similar gangs in whatever country. Almost all the countries on the continent are annoyed by banditti, who are so numerous, and united among themselves by so strict and inviolable laws, that no police can afford sufficient security against their depredations. In the eastern part of Sicily, called Val Demoni, especially, they are so formidable, as to have almost the absolute command of the whole district. In the innumerable caverns and subterraneous passages of Mount Etna, they are completely safe from the pursuit of troops; and as they are to the last degree determined and vindictive, the inhabitants, rather than venture to offend them, submit, in silence, to their most violent outrages. From these circumstances, their company has become so numerous and powerful, that the prince of Villa Franca has been induced, from motives of policy, as well as from a regard to safety, to declare himself their patron and protector. Such of them as chuse to leave their mountains and forests, meet with good encouragement and certain protection in his service; and are treated with unlimited confidence, which they have never been known to abuse. They wear the prince's livery, and are distinguished also by the badge of their order, which commands universal awe and respect.

In many circumstances, indeed, these banditti are more entitled to respect than the majority of their countrymen. Criminal as they are with regard to society in general, their notions of honour are highly refined and romantic. Their promise is inviolable, and their friendship or protection, when once engaged, may be relied on with unreserved confidence. Even magistrates have often been obliged to protect and court them; and as those of their number, who are enlisted in the prince's service, are known and respected by all the banditti in the island, the persons of those whom they take under their protection are always held sacred. Most travellers, therefore, endeavour to hire a couple of these heroes from town to town; and though their pay be high, it is more than saved by their care to secure their *protégés* from every kind of imposition. "Indeed," says Mr Brydone, "I think they impose upon every body except us; for they tax the bills according to their pleasure; and such cheap ones I never paid before." See Brydone's *Tour through Sicily and Malta*, Lett. 4. and 5. (x)

BANDON BRIDGE, a large and flourishing town of Ireland, in the county of Cork, situated on the fine river Bandon, which rises in the mountains of Carbery, becomes navigable by large sloops near Inishonon, and falls into the harbour of Kinsale. This town was built in the year 1610, by Richard Boyle, the first Earl of Cork, in the middle of an impassable marsh, and was inclosed by strong walls. A charter of incorporation was obtained

* This word should always be employed in the plural. Nothing is more frequent, however, than to say, a *banditti*, a *banditti of robbers*, which in our opinion, is improper; it should be, a *gang of banditti*, or, a *band of robbers*. DU PONCEAU.

for it in 1613. Stuffs, camblets, and shags, were manufactured in Bandon Bridge to a great extent, but of late these manufactures have considerably declined. Coarse green linens, 27 inches wide, called *wittery*, ticken of an excellent quality, and cotton, are also manufactured here. The town belongs principally to the Duke of Devonshire. Population about 12,000. W. Long. 8° 48', N. Lat. 51° 56'. See Smith's *Cork*, vol. i. p. 236. (j)

BANFF, (sometimes written, more conformably to the pronunciation, BAMFF) a royal borough, and the principal town of Banffshire, is situated on a rising ground near the influx of the Doveran into the Moray Firth. It is supposed to have derived its name from the district Boin, or Boyn, an opinion which is rendered probable by the old orthography Boineffe. It unites with Cullen, Elgin, Inverury, and Kintore, in sending a representative to the Imperial Parliament. The charter of the borough was granted by Robert II. in 1372, and afterwards confirmed by James VI. and Charles II. The tradition that the town was erected into a royalty by Malcom Canmore is not supported by any evidence. Part of the ancient castle of Banff still remains. It was a constabulary under the hereditary government of the Earls of Buchan. The municipal government of the town is under the direction of a provost, four bailies, and twelve counsellors. The population is about 3000.

Banff is generally considered by strangers as a very neat town. There is a fine bridge of seven arches over the Doveran. A very handsome church, capable of containing 1500 persons, was built in 1790, and, besides this established place of worship, there are three chapels, or meeting-houses, for persons belonging to the episcopal and catholic communion, and for the adherents of the church of relief. A town-house with an elegant spire was built in 1798, and at the same time a new prison was constructed on the principles recommended by Howard. In 1786, an academy was substituted in place of the public schools for the different branches of education. This seminary is superintended by a rector, assisted by four other masters, who teach Latin, Greek, French, geography, arithmetic, book-keeping, and the different elementary branches of mathematics, &c. A charity-school was also established a few years ago. There are several private English schools, and two female boarding-schools. Besides a circulating library, well furnished with the best authors, there is a society of gentlemen who are making a good collection of books. The poor are liberally provided for from the public funds, and a great number of the lower classes have formed themselves into friendly societies. The weekly market, held on Friday, is amply supplied with provisions. The manufactures most deserving of notice are thread, linen, stockings, soap and candles, brewing, ropes and sails, bricks and tiles. The Bank of Scotland and the Aberdeen banking company have agents at Banff, who transact business to a considerable amount annually.

The salmon fishing on the Doveran produces a great yearly revenue to Lord Fife and the other proprietors. The harbour of Banff was finished in 1775. The principal exports are salmon, cod, and ling, butter and cheese, meal, barley, oats, &c. Imports, iron, wine, spirits, salt, &c. The number of vessels in 1798, was 22,—tonnage, 1943,—seamen, 137. West Long. 2° 33', North Lat. 57° 41'. Distance from Edinburgh 165 miles. (s)

BANFFSHIRE, a maritime county in the north of Scotland, bounded on the north by the Moray Firth, on the east and south by Aberdeenshire, and on the west by

the county of Moray. The greater part of it was formerly included in the province of Moray, the bounds of which are supposed to have been nearly the same with those of the ancient territory of the *Vacomagi*. The south-west angle of the county is comprehended in the range of mountains distinguished by the name of the Highlands, and throughout this subdivision the Gaelic language is generally understood, though the English is also in common use. This bleak district is named Strath-Aven, and the inhabitants are said to be still enslaved to the superstitious notions of their savage ancestors. The other districts of the county, viz. Balvenie, Boyne, Enzie, part of Strathdoveran, and part of Buchan, present a variegated surface to the eye, and contain a large proportion of very fertile land, though not very highly cultivated. Strath-Isle on the east, Strath-Fiddich and Glenlivet on the west, are peculiarly fruitful. Throughout this county there are many beautiful straths and glens, containing an immense variety of picturesque scenery. The woods, belonging to the Duke of Gordon, Lord Findlater, and Lord Fife, are of very great extent, and a few magnificent houses are built on the romantic banks of the different rivers. On the boundary between the counties of Banff and Moray, the Spey, one of the finest and largest rivers in Scotland, is fed by the Aven, Livet, Fiddich, Dulan, &c. On the eastern boundary, the Doveran, and its tributary streams, the Boyne, the Isle, &c., water a rich and varied country. Some of the grandest and most interesting hills in Britain enliven this charming district. Cairn-gorum, on the extremity of the county, rises 4050 feet above the level of the sea. Belrinnes is 2690 feet high, Knockhill 2500, Bin of Cullen 1100. Some of these hills are planted to the very summit. The hills of Alvah, Benlageen, Durn, Lurg, and Altmore, are also lofty and beautiful.

The climate, though healthy in general, is cold and wet. The soil on the flat grounds is, for the most part, light and sandy;—on the hills a deep clay is more prevalent. A prodigious quantity of lime-stone is produced in the county; but from the want of coal, it has never been very extensively used. The lands upon the whole, when tolerably improved, yield very abundant crops.

The late Earl of Findlater made many laudable exertions to promote the improvement of agriculture; but, notwithstanding the encouragement which he so liberally afforded, and the example which he set, the progress of that useful art, in Banffshire, has not been very rapid. Inclosures were very partially introduced a few years ago; and the badness of the roads long operated as a great discouragement. It is to be hoped, however, that the public spirit and intelligence of the gentlemen of this county will speedily overcome the few obstacles which still remain to be surmounted. On the banks of some of the rivers, large fields of uncommonly rich pasture are to be found.

With the exception of a few small bays and creeks, the line of coast is bold and precipitous.

The principal minerals are limestone, granite, clay, slate, freestone, alum, Portsoy marble, iron, lead, quartz, topaz, asbestos, rock-crystal, &c. Mineral waters abound in various places. The chief manufactures are spinning, weaving, bleaching, tanning, flax-dressing, distilling. The salmon fishing on the Spey and the Doveran is of very great value to the proprietors. Vast quantities of haddocks, whittings, flounders, mackarel, turbot, cod, ling, tusk, skate, crabs and lobsters, are caught on the

coast; and of these, as well as of the salmon, a great proportion is sent to supply the London market.

Perhaps the greatest disadvantage under which Banffshire labours is the want of coal. In the inland parts of the county peat is the only fuel which the labouring classes are able to procure.

Many remains of antiquity may be traced in this county, particularly tumuli, upright stones, cairns and Druidical circles,—various ruins of castles, as Auchindune, Balveny, Edinglassie, Galval, Deskford, Scuth, Grange, Inchdrewer, Banff, and the castle near Cullen. For several ages the shores of the Moray Firth were almost incessantly molested by the hostile descents of the Danes. Many spots are pointed out where these piratical invaders were defeated with dreadful carnage, particularly at Gamrie, at Cullen, and at Mortlach, where great victories were successively gained over them, about the end of the 10th and beginning of the 11th century, by the chief of Buchan, Indulf king of Scots, and Malcolm II. In the same age it is believed that a number of religious houses were founded near the scenes of these successful engagements.

The chief towns and villages in Banffshire are, Banff, Cullen, (both royal boroughs,) Portsoy, Macduff, Gardenston, Troup, Keith, New Mill, Buckie, Portcasay, Findochtic, Portnockie, Tammtoul.

Cullen, formerly Invercullen, was a constabulary as early as the days of David II. For several ages it was subject to the Earls of Findlater. The council of this borough consists of 19 members. The manufactures are linen and damask. Population nearly 1000.

Portsoy, in the parish of Fordyce, contains above 1000 inhabitants, who are engaged chiefly in fishing, or in the manufacture of thread and linens.

Macduff, in the parish of Gamrie, is about a mile distant from Banff. It now possesses a tolerable harbour, and sends a number of vessels to London, Leith, &c. The population exceeds 1000.

The greatest length of the county is 58 miles, the breadth 24. It contains 750 square miles, and is divided into 23 parishes. In 1801, the population was stated at 35,807, a lower number than either Dr Webster's calculation in 1755, or Sir John Sinclair's in 1798. The valued rent is 79,200*l.* Scots; and in 1798, the real rent was rated at 43,490*l.* sterling. (♣)

BANGALORE is a strongly fortified town in Hindostan, in the Mysore country, and being the bulwark of the Mysore country towards Arcot, is a place of great political importance. The town, or pettah, is of great extent, and the palace erected by Tippoo is a very magnificent structure. Silk and woollen goods are manufactured in the neighbourhood. The fort of Bangalore having been destroyed by Tippoo after the British retired, Purneah was putting it into repair in 1804, and making it even stronger than before. See Lord Valentia's *Travels*, vol. i. p. 411. (w)

BANGOR, a small city of Caernarvonshire, in North Wales, consisting of an irregular street, situated on the banks of the Deva, in a narrow valley, between two low ridges of slate rock. In the neighbourhood of Bangor, on the shore of the bay of Beaumaris, is the harbour of Penrhyn, where the slates of Lord Penrhyn's quarries are shipped for London and other towns in England. A new harbour has lately been erected at the expense of Dr Warren, bishop of Bangor. The revenues of the diocese are extremely small. Number of houses 304. Population 1770. (j)

BANJAR-MASSIN, or **BENDER-MASSIN**, the capital of a kingdom of the same name, in the southern part of the island of Borneo. The king of Banjar-Massin is the most powerful monarch in the island, and assumes the title of Emperor of Borneo. The houses of the capital, which are numerous, are chiefly built of bamboos, though some of them are of timber. They are in general so large, that one of them would be sufficient to lodge 100 families in separate apartments. The Dutch have a factory and a small fort here, partly for the purpose of purchasing the rough diamonds that are found in the kingdom. Their principal object, however, is the purchase of pepper, of which the king obliges himself to deliver 600,000 pounds annually, at the rate of three stivers per pound. The trade, which is carried on in diamonds, gold, wax, canes, and sago, is comparatively trifling. The kingdom of Banjar-Massin extends about three degrees to the north, and its width from east to west to the river of Cataringa is 211 English miles. Cataringa, the last place in this kingdom, is by far the richest on all the coast. It raises for the royal service about 7200 armed men. East Long. 114° 50', South Lat. 3° 10'. See **BORNEO**. (q)

BANIANS, the name of a religious sect in the dominions of the Mogul. These people, believing firmly in the transmigration of souls, will, on no consideration, kill any living creature, or eat its flesh; but, on the contrary, will use their utmost endeavours to release even the most noxious animals, if they see them in danger of perishing. They account all other nations impure; and are so scrupulously fearful of pollution, that they will break a cup which has been used or even touched by a person of a different religion; nor will they enter the same pond in which a stranger has bathed, till they have emptied it completely, and filled it with pure water. Nay, so excessive is their anxiety to preserve their purity, that if they happen to be touched even by persons of their own sect, they cannot eat nor enter their houses, till they have undergone a thorough ablution. They wear at their necks a stone about the size of an egg, which is perforated in the middle, and has three strings drawn through it. As this stone, which they call *tamberan*, represents their great god, it procures them very high respect among all the Indians.

The name *Banians* is likewise applied in general to all the idolaters of India, as distinguished from the Mahometans, and is more particularly appropriated to one of the four principal casts into which the Indians are divided: the other three casts are the Bramins, or priests; the Rajaputs, or men of the sword; and the artists, or labourers.

In their shaster, or statute book, the proper Banians are distinguished by the name of *Shuddery*, which comprehends all persons engaged in traffic or merchandise. Their name, in the Bramin language, signifies innocent and harmless; and nothing can be more expressive of their real character; for they would not hurt the most insignificant creature, and they bear injuries with more than Christian meekness. They are not distinguished from the other Hindus by any peculiar religious tenets; but of the eight general precepts delivered by Bramaw, the Indian legislator, two are supposed more immediately to refer to the Banians, as they enjoin veracity and honour in all their speeches and transactions, and forbid circumvention in buying or selling.

A great proportion of the inland trade of the Indies is carried on by the Banians, particularly in the penin-

sula on this side of the Ganges. Though extremely expert in commercial transactions, they are equally remarkable for their honesty. Persons of this cast are generally chosen as the brokers of the English, Dutch, and French companies, with whose stock and cash they are almost constantly entrusted. The Banians are also bankers; and their bills of exchange are current almost through the whole of the East Indies. They have, besides, a kind of standing bank, in which persons may deposit their money, and lift it again when they find it convenient.

The form of contract which they employ in their bargains deserves to be described. The transaction is carried on in the most profound silence, by touching one another's fingers: the buyer takes off his girdle, and spreads it on his knee; and both parties, having their hands beneath it, can, by the mere intercourse of their fingers, mark, even to the lowest denomination, the price demanded, offered, and accepted. When the

seller takes the buyer's white-hand, it denotes a thousand, and as many times as he squeezes it, so many thousand pagods, rupees, &c. are offered—every finger denotes a hundred; a half-finger, to the second joint, fifty; and the small end of the finger, to the first joint, ten.

Almost from childhood the Banians are accustomed to trade, and to that gentleness of disposition and of manners, which is characteristic of their cast. Their slaves are treated with great humanity. In general, they are extremely frugal; but, when they settle their children, they launch out into great extravagance. Their women are remarkable for their chastity; nor do husbands allow their wives the least intercourse with strangers. This restraint they justify by a favourite proverb: "If you bring butter too near the fire, you can hardly keep it from melting." (*u*)

BANISTERIA, a genus of plants of the class Decandria, and order Trigynia. See BOTANY. (*w*)

BANK.

IN commercial language, a bank is a repository or an establishment, for the purpose of receiving the money of individuals, either to keep it in security, or to improve it by trafficking in goods, bullion, or bills of exchange; and it may be either of a public, or of a private nature. A public bank is generally regulated by certain laws enacted by the government of the state, which constitute its charter, limit its capital, and establish the rules by which it is to conduct business. A private bank, on the other hand, is merely a contract among individuals, for carrying on a trade in money and bills; and the responsibility of the partners is the only security of those who transact with it.

Banks are properly commercial institutions, which, by affording credits, or issuing notes, as the representative of money, enable merchants, with greater facility, to buy and sell commodities at home or abroad. The produce of one country is thus exchanged with that of another, by means of a medium to which an ideal value is attached. Hence the great utility of banking establishments in all commercial countries.

Among the ancients, the term *banker* implied something different from its modern signification; and conveyed an idea corresponding with the profession of an agent, broker, or money-lender. Bankers were called *argentarii* and *nummularii*, by the Romans; and they lent out the money of private persons on interest, wrote the necessary deeds, and assisted in buying and selling all kinds of property.

The first establishment of banking in a regular and systematic form, took place at Venice, about the middle of the 12th century; and it arose from the necessities of the state. Duke Vitale Michel II. being involved in expensive wars with the empire of the West, and the Grecian Emperor Manuel, embarrassed the finances of the republic; and to relieve it from the pressure of its difficulties, he had recourse to a FORCED LOAN; the contributors to which were made creditors, and received interest at the rate of four per cent. per annum. "The Chamber of Loans" (*la Camera degl' imprestitii*) was established for the management of this fund, and regular payment of the interest; which, gradually improv-

ing its plan, at last formed itself into the more perfect institution of the Bank of Venice.

This celebrated bank has served as a model to almost every similar establishment in succeeding ages. Its capital is 5,000,000 ducats, for which the republic is security. It is properly a board for deposit, credit, and interest. By an edict of the state, all payments of wholesale merchandise and bills of exchange must be made in *banco*, or bank-notes; and all debtors must lodge their money in the bank, that their creditors may receive payment in *banco*, which is done, by transferring the amount from the name of the one to that of the other, or by writing off the sum from the account of the debtor, and placing it to that of the creditor. Payments are made in this manner, without the intervention of gold or silver; but there are exceptions to this rule, in cases of retail trade, or when foreigners wish to carry off the precious metals. All the riches of the state thus flowed into the bank, and through various channels were again diffused among traders, to give activity to the extensive commerce of this opulent and once powerful city. From its good faith, and the regularity of its transactions, the Bank of Venice has always maintained a high character in Europe; and, on some occasions, its obligations have been more esteemed than the bonds of kings.

During two centuries and a half, the Bank of Venice was unrivalled; for, so gradual is the progress of improvement, that human knowledge is only matured by the experience of ages; and it was not until the year 1401, that the magistrates of Barcelona established a bank in that city. It was called the "Table of Exchange," (*Taula de Cambi*), and was properly a bank of exchange and deposit. Foreign bills were negotiated with the same liberality as those of the citizens; and accommodations were extended to strangers as well as to natives. It was altogether calculated for the encouragement of both internal and external commerce; and the funds of the city were pledged as security for the responsibility of the bank.

In the year 1407, the Bank of Genoa commenced; but previous to this time, the republic borrowed large

sums of money from the citizens, assigning certain branches of the revenue for the payment of the interest; and a Board of Management, composed of the most respectable citizens, was appointed to conduct the loans, pay the interest, and account to government for the funds entrusted to its care. From this circumstance, the Genoese claim the merit of establishing a bank as early as the Venetians; but it is evident, that the transactions of this Board were only an approximation to banking. In process of time, however, the multiplicity and extent of these funds induced disorder and confusion, and it was deemed expedient to consolidate the whole into one capital stock, to be managed by a bank called "THE CHAMBER OF ST GEORGE," to be governed by eight protectors, annually elected by the creditors and stockholders. Under this form of government, the affairs of the bank were prosperously conducted; but the farther increase of the public debts, the accession of towns and territories, among which was the little kingdom of Corsica, made the business of the bank greatly more complex; and the inconvenience of annual successions of new protectors becoming apparent, determined the Genoese, in the year 1441, to elect eight new governors for the management of the bank, of whom only two were to go out every year.

Before the discovery of a passage to the Indies, by the Cape of Good Hope, the Venetians enjoyed a monopoly of the lucrative trade of the East, by means of the Mammelucks of Egypt, with whom they were leagued by policy and interest, which diffused opulence and wealth throughout Italy. This extensive commerce created and gave circulation to bills of exchange, the credit and currency of which were universally acknowledged when they bore the signature of the Banks of Italy; and for several centuries there were no other establishments of the kind in Europe.

The Bank of Amsterdam was established on the 31st January 1609. The magistrates of the city, under authority of the States, declared themselves the perpetual cashiers of the inhabitants, and that all payments, above 600 guilders, (but afterwards reduced to 500,) and bills of exchange, shall be made in the bank, which obliged merchants to open accounts with it for the payment of their foreign bills. The extensive commerce of Amsterdam involved such a variety of transactions, that the expediency of regulating them became evident; and no measure could more effectually secure property, check law suits, and prevent frauds, than the establishment of a bank-office, in which all receipts and payments were registered in books kept open for the purpose. Dr Smith ascribes the origin of this bank to the debased state of the current coin of Holland, which the trade of Amsterdam brought from all quarters of Europe; and which was sold at a reduction of nine per cent. below the money of the mint. Merchants, in such circumstances, could not always find standard money to pay bills of exchange, the value of which was uncertain, and accordingly operated against the trade of the United Provinces with foreign nations. But as the bank received the light or worn coin at its real intrinsic value in the good money of the country, and gave credit for the amount in its books, an invariable standard was thus established, that tended greatly to simplify and facilitate the operations of commerce.

The beneficial effects of this establishment in Holland were soon perceived; and bank-money immediately bore a premium, or *agio*, which is a term to denote the

difference of price between the money of the bank and the coin of the country. When we consider that coin is only a representative of commodities, and that its utility arises solely from its being a generally acknowledged standard of value, by which mankind, in the civilised state of society, are enabled to calculate the price of articles of exchange, it is not surprising, that bank-receipts, which represent property also, and, at the same time, are not liable to risk, danger, or deterioration of any kind, should be held in higher estimation than coin, which is exposed to robbery and all sorts of casualties. In all countries, where banks have been regular in their transactions, and their responsibility unbought, their paper has carried a premium, more or less, according to circumstances; and the *agio* of Amsterdam was generally about five per cent.

The amount of the capital of the Bank of Amsterdam was never exactly ascertained. It was originally constituted by deposits of coin; and there was full value in its coffers for all the credits and receipts it issued. The bank, however, gave credits and receipts also upon deposits of gold and silver bullion, at the rate of five per cent. less than the mint price of such bullion, which was restored again to the owner, if he called for it within six months, upon paying one fourth per cent. if the deposit was in silver, or one-half per cent. if in gold. But if the term of six months was allowed to expire, the bank retained the bullion at the price stated in its books.

The advantage of making deposits in this bank is twofold. *First*, The credit enables the merchant to pay his bills of exchange. *Second*, The receipt gives him an opportunity of selling his bullion at an advance of price, if the market shall fluctuate in his favour. Although none can draw out bullion without producing a receipt, and re-assigning bank-money equal to the price at which the bullion had been received, yet it is not absolutely necessary that both credit and receipt should always remain in the hands of the same person; as he who has the receipt will find bank-money to buy at the ordinary market price, to enable him to relieve the bullion; and the owner of credit will, at all times, find receipts in abundance. But to prevent any extraordinary rise in the price of bank-money or receipts, which speculation, or other causes, might sometimes induce, the bank adopted the resolution of selling bank-money for the current coin, at an *agio* of five per cent; and of buying it, at the rate of four per cent.

It is generally understood, that the Bank of Amsterdam keeps in its repositories the full value in money or bullion of all the receipts it has issued; but it is not absolutely necessary to do so, as many of these receipts have expired. But that there is value in the bank equal to all the demands that can be made upon it, there is little doubt; for the city is guarantee that this should be the case, and the directors, who are annually changed, compare the treasure with the books, and would therefore detect any acts of fraud or imposition.

The four reigning burgomasters are invested with the direction of the bank; and the city of Amsterdam derives a considerable revenue from it, which arises from the following sources:—For all deposits, a fourth or half per cent. must be paid—from every person who opens an account, a fee of ten guilders is exacted; and for every additional account, three guilders three stivers—for every transfer two stivers, or six stivers if the transfer is less than 500 guilders. If any person shall

overdraw his account, he is fined three per cent. on the amount; and his order is set aside. There is also a considerable profit from the sale of foreign coin or bullion, which is always kept till it can be sold to advantage, and likewise by selling bank-money at five per cent. *agio*, and purchasing it at four per cent. From these various resources, the Bank of Amsterdam became rich and prosperous; and it was supposed to retain in its repositories more gold and silver than any other establishment of the kind in Europe.

Previous to the year 1694, there were only four considerable banks in Europe; but on the 27th July of that year, a charter was granted by William and Mary, for establishing the BANK OF ENGLAND, which, for opulence and extent of circulation, is now the greatest in the world. William Paterson, a native of Dumfriesshire, in Scotland, was the projector of this bank, and, it is said, he took the Bank of St George, in Genoa, for his model. Michael Godfrey, a gentleman of great consideration in the city of London, assisted Paterson to arrange the establishment. The charter was granted for the term of twelve years; and the corporation was determinable on a year's notice. A governor, deputy-governor, and twenty-four directors, are annually elected from the proprietors, for managing the affairs of the company, but not above two-thirds of the directors of the preceding year can be chosen. A governor must be possessed of 4000*l.* stock, and a director of 2000*l.* before he is eligible; and it is requisite, that an elector should hold 500*l.* stock to entitle him to vote at general courts.

The original capital subscribed by the proprietors was 1,200,000*l.* sterling, which was lodged in the exchequer at the rate of 8 per cent. interest; and government allowed 4000*l.* additional in name of house expenses, so that the bank received 100,000*l.* annually. In 1697 the bank was allowed to ingraft 1,001,171*l.*: 10: 0 sterling on its capital stock. This enlargement was intended as a support to public credit, for tallies had been at from forty to sixty per cent. discount, and bank notes at twenty per cent. which was occasioned by the bank discontinuing to pay its notes during the great recoinage of the silver at that time going on. In terms of the act of the 7th Anne, cap. 7. the bank advanced 400,000*l.* on the original annuity of 100,000*l.* and there had been paid into the exchequer, in all, 1,600,000*l.* In pursuance of the same act, the bank cancelled Exchequer bills to the amount of 1,775,027*l.*: 17: 10½, at 6 per cent. interest, and was allowed to double its capital. In 1708 the advances to government amounted to 3,375,027*l.*: 17: 10½ and the capital of the bank was now 4,402,343*l.* By a call of 15 per cent. in 1709, there was paid in and made stock the sum of 656,204*l.*: 1: 9*d.*; and by another of 10 per cent. in 1710, 501,448*l.*: 12: 11. In consequence of these two calls, the bank capital amounted to 5,559,995*l.*: 14: 8. By the 3d of George I. c. 8. the bank cancelled 2,000,000*l.* of exchequer bills, which made the advance to government 5,375,027*l.*: 17: 10½. By the 8th of George I. c. 21. the bank purchased South Sea Company stock to the amount of 4,000,000*l.* To enable the bank to effectuate this purchase, it increased the capital stock 3,400,000*l.* by subscription, in the year 1722; and at this time, the bank had advanced to the state 9,375,027*l.*: 17: 10½; but its capital stock was no more than 8,959,995*l.*: 14: 8. It appears, from this statement, that the bank advanced a larger sum to government than the whole amount of its capital, on which it

paid a dividend to the proprietors. And this circumstance shews, that the bank possessed an undivided capital, which had accumulated from its establishment, which is the fact, and it has continued to have an undivided capital ever since. For in the year 1716 the bank had advanced to the public, on different occasions, 11,686,800*l.*; and the capital on which it divided had been raised, by several calls and subscriptions, to no more than 10,780,000*l.*

In pursuance of the 4th George III. c. 25. the bank paid to government 110,000*l.* for the renewal of its charter, without stipulating for repayment of principal or allowance of interest. At the same time, (1764) it advanced 1,000,000*l.* towards the supplies, on exchequer bills, to be repaid in the year 1766. The charter was accordingly extended to the 1st August 1786, and the dividend on the company's stock was raised from 4½ to 5 per cent.; and at Michaelmas 1767, it was farther raised to 5½ per cent.

Soon after the establishment of the bank, it assisted government with money in anticipation of the land and malt taxes; and also by advances on exchequer bills, and other securities. In 1781 the advances in this way amounted to 8,000,000*l.*, in addition to the permanent debt of 11,686,800*l.* On the condition of advancing 2,000,000*l.* on exchequer bills, at 3 per cent. interest, to be paid off from the sinking fund within three years, the bank again obtained an extension of its charter to August 1812. To enable it to make good this advance, it was thought necessary to make a call of 8 per cent. on the capital stock, which was now increased to 11,642,400*l.* and the dividend was raised to 6 per cent. In February 1782, the total advances to government on the land and malt taxes, and exchequer and treasury bills, amounted to 9,991,678*l.*; but in 1786 this sum was reduced to 6,634,872*l.*; and from that period to the commencement of the late war in 1793, the amount of advances on these funds has fluctuated from seven to nine millions sterling. In February 1788, the dividend was raised to 7 per cent., which continued to be the rate of division until April 1807.

In the year 1800 the charter was renewed by the 40th George III. c. 28, and continued to 1st August 1835, on condition of 3,000,000*l.* being advanced for the public service, without interest, for six years, ending on the 5th April 1806. In that year, however, it was stipulated, and accordingly enacted by the 46th George III. c. 4, that these three millions should remain with the public till six months after the ratification of a definitive treaty of peace, at 3 per cent. interest per annum, which is a present to the nation of 60,000*l.* a year, during the continuance of the war; and which shews the resources and profitable trade of the Bank of England.

The circulation of the notes of the bank has not been so extensive as was generally supposed; and has seldom exceeded the amount of the capital until of late years. In February 1787, no more than 8,688,570*l.* were in circulation; in 1790, 10,217,360*l.*; in 1795, 13,539,160*l.*; and in 1796, 11,030,110*l.* But by issuing small notes, the circulation was greatly increased; and in 1805 amounted to 18,397,880*l.*; in 1806, to 17,093,570*l.*; in 1807, to 16,621,390*l.*; and at present (1810) to about 21,000,000*l.* sterling.

In the year 1797, the amount of the public debt to the bank, and the vast drainage of coin and bullion for the payment of loans, exchequer bills, &c. conjoined to the apprehension of invasion, produced a *run* upon the

bank, and it was found necessary to stop payment in cash. The privy council issued an order for that purpose on the 26th of February; and an act was passed by parliament, suspending payments for bank notes for a limited period, which suspension was renewed annually; but by subsequent acts it was continued until six months after the ratification of a definitive treaty of peace.

From the reports of the committees of secrecy appointed in 1797, to inquire into the state of the bank, it appeared, that on the 5th February of that year, the total credits of the bank were 17,597,293*l.*; and the debt owing by government was 13,770,390*l.*, thus leaving a balance in favour of the bank of 3,826,903*l.* Since that time, the profits of the bank have been considerably augmented, and the proprietors have occasionally received bonus's in addition to the usual dividend of 7 per cent.; but in April 1807, the permanent dividend was fixed at 10 per cent. per annum.

According to Mr Allardice's statement, the annual income, or profits of the bank, arise from the interest of the permanent debt received from government; the allowance for managing the public debt; the allowance for receiving the contributions to loans, and paying the dividends on the public funds; the allowance for temporary advances on exchequer bills, &c.; the interest of stock held by the company; the discounting of mercantile bills of exchange, and other less important sources; making altogether about 1,437,752*l.* sterling, from which fall to be deducted the interest of the capital stock of 11,642,400*l.*, and all losses, charges, and expenses of management.

By the original act which constituted this bank, as well as by the various subsequent statutes, numerous privileges are conferred on the governor and company of the bank of England; and salutary restrictions interposed for the protection and welfare of the institution. They are authorised to purchase and retain lands, &c. with all the powers incident to other corporations; they are restricted from trading with any of their effects in goods or merchandise of any kind; but are permitted to deal in bills of exchange, and in buying or selling bullion, gold, or silver, or in selling goods mortgaged to them, if not redeemed within three months after the time stipulated for such redemption; or such goods as shall be the produce of the lands belonging to the corporation.

The stock of the bank is accounted a personal, and not a real estate; but goes to executors, and not to heirs. A devise of stock, therefore, is valid, if attested by three credible witnesses. All contracts or agreements for buying or selling stock must be registered in the books of the bank within seven days, and the stock transferred within fourteen after such contracts have been entered into, or otherwise they will not be effectual. They are allowed to call for such sums of money, from the proprietors, in proportion to their respective interests, as a general court shall deem necessary; and if such calls shall be refused, it is lawful for the bank to stop the payment of the dividends of the defaulters until the same shall be made up. They are also empowered to borrow money under their common seal, or upon the credit of their capital stock, at such interest as they shall think fit, although the same may exceed the legal interest of the country. No body politic or corporate, or other persons united in partnership, above the number of six, can borrow money on

their note payable sooner than six months, during the continuance of the charter of this company, who are declared to be a corporation, and to have the exclusive privilege of banking.

The character and security of the Bank of England are permanently established by the many provisions for its stability. But to ascertain the solidity of its bank-paper, or the reliance that the public may place in its engagements, it is only necessary to state, that value is received in security, or bills payable at a fixed time, for every note that is issued, so that there is always value in the bank equal to all the notes in circulation. This value consists of bullion or coin; government securities payable for receipts, or at determinate periods; and bills of exchange with three solvent names, at dates not exceeding two months.

Since the first establishment of the bank, it has not sustained any serious loss. So certain is the payment of bills drawn and indorsed, that, in ordinary times, the arithmetical calculation of the chance of loss is only as one to three hundred thousand: a proportion so insignificant, that no injury is to be apprehended from such a cause. Were a *run* to be made on the bank, and the owners of notes to insist on payment in specie, the discounting of bills would be discontinued, and consequently the whole notes in circulation would return to the bank in two months, in payment of the advances to government and the bills of individuals. The bank, therefore, has it always in its power to call in its notes, merely by refusing to accommodate government, or to discount bills of exchange.

But the mercantile people of England have well grounded reason to place confidence in the paper of the bank; and it must be highly gratifying to our national pride, to think, that bills of exchange can be obtained in any part of Europe for our bank notes, on the same terms as for specie.

The profits of the bank are supposed to be greatly accumulating; but as the directors are sworn to secrecy, it is only from circumstances, and the communications made by them to general courts, that we can conjecture as to that subject.

Within a year after the establishment of the Bank of England, a royal charter was granted for instituting the Bank of Scotland. The same William Paterson who projected the Bank of England, was also the projector of this bank. He seems to have been one of those enterprising men to whom the trade and prosperity of this country are so much indebted. The original capital of the bank was 1,200,000*l.* Scots money, or 100,000*l.* sterling; and its affairs are managed by a governor, and deputy, with 12 ordinary and 12 extraordinary directors, annually elected by the proprietors of stock, to whose inspection the bank submits its accounts once a year. There are twenty branches belonging to the bank, in different towns in Scotland, under the management of agents, who in general receive fixed salaries for their trouble, and altogether the affairs of the bank are very prosperous.

In the year 1727, the Royal Bank of Scotland was erected by charter. It is managed by a governor and deputy, with eighteen ordinary and extraordinary directors; and its accounts are exhibited four times a year. The business of this bank is conducted on a plan similar to that of the Bank of Scotland; and the concern is also very profitable to the proprietors.

In almost every town in Scotland, a bank has been est-

tablished, and in some, two or three. But these banks are private copartneries, for the purpose of discounting bills of exchange, and selling drafts on London, Edinburgh, &c. for the accommodation of merchants and others. They also, in common with the chartered banks of Scotland, issue cash accounts or loans to individuals on bonds of security; and traffic in money and bills to a very great extent.

The French nation, though less enterprising than the English, in every thing relative to commerce, have yet, in some respects, successfully imitated them. But in the particular instance of banking they have not been so fortunate, owing more to causes connected with their political institutions, than to any want of knowledge, genius, or activity in the people.

In the year 1716, a bank was erected in Paris by the celebrated John Law of Lauriston. The object of this bank, according to Mr Law's professions, was, "to increase the circulation of money, put a stop to the progress of usury, facilitate the exchange between Paris and the provinces, augment the circulation of manufactures, and enable the people to pay more easily the heavy taxes to which they were subjected." The letters patent establishing this bank stipulated, that the stock should consist of 1200 *actions*, or shares of 1000 crowns of 5000 livres each, at the rate of forty livres the marc; so that each share was worth 250*l.* sterling, and the whole stock of the bank 300,000*l.* sterling.

The regulations for the government of this bank were wise and salutary. It was declared, that the bank securities belonging to, as well as the money lodged by, foreigners, should not be subject to confiscation, even in case of war with the nations to which the proprietors belonged; that all questions relative to the concerns of the bank should be determined by a plurality of votes; those possessing from five to ten shares to have one vote, from ten to fifteen two votes, and so on proportionally; that the accounts should be balanced twice a year, and two general courts held annually, at which the company's affairs should be discussed, and the dividends settled; that the bank should not undertake any sort of commerce whatever; that the notes should be payable at sight, and signed by the director and one proprietor; but under the revision of an inspector appointed by the government.

This bank, of which Mr Law and his brother William were the principal partners, assumed the firm of the general bank of *Law and Company*; and soon obtained the confidence of the public. As the notes they issued bore on the face of them, that they should be paid in crowns of the weight and standard of the day on which they were granted, a security was thus formed against the arbitrary practice of varying the coin; and on this account, they were preferred by many to specie. The balance of exchange with Holland and England rose in favour of Paris, at the rate of 4 to 5 per cent.; and the affairs of the bank were so prosperous, that at a general meeting held the 20th December 1717, a dividend was ordered at $7\frac{1}{2}$ per cent. for six months. There can be no doubt, but this bank would soon have rivalled that of Amsterdam, or of England, and produced consequences highly beneficial to France; but the arm of power interfered, and changed the institution from a private to a public concern. By act of council, bearing date the 4th December 1718, the public were informed, that his majesty had taken Mr Law's bank into his own hands, under the name of the *Royal Bank*, of which Mr Law

was appointed director general, and branches were established at Lyons, Rochelle, Tours, Orleans, and Amiens.

The bank now proceeded on public credit, or, in other words, was entirely dependent on the will of the sovereign; and, as the schemes of monarchs are seldom limited by moderation or reason, it embraced objects so vast and extensive, that all Europe looked with anxiety for the issue. It was proposed to vest the whole privileges, effects, and possessions of foreign trading companies, the great farms, the mint, the general receipt of the king's revenues, and the management and property of the bank, in one great company, which, having in their hands all the trade, taxes, and royal revenues of the kingdom, might multiply the notes of the bank to any extent they pleased. Accordingly, a commercial company was established by letters patent in August 1717, under the name of the *Company of the West*, to which was granted the whole province of Louisiana, through which the noble Mississippi flows; and from this circumstance the operations of the company obtained the name of the *Mississippi System*. Of this company 200,000 shares were issued at the rate of 500 livres each, bearing interest at the rate of 4 per cent, after the first year, exclusive of the profits of the trade.

On the 4th September 1718, the farm of tobacco was made over to the Company of the West, who engaged to pay 2,020,000 livres advanced rent to the king. On the 15th December following, they acquired the charter and effects of the Senegal company; but the most important grant they obtained was in May 1719, when an edict was published, transferring to them the exclusive privilege of trading to the East Indies, China, and the South Seas, together with all the possessions and effects of the China and India companies, on condition of paying the lawful debts of these companies now dissolved. On this occasion, the Company of the West assumed the title of the *Company of the Indies*; and 50,000 new shares were ordered to be constituted, at the rate of 550 livres each, to be employed in satisfying the creditors of the old companies, in building vessels, and in other preparations for carrying on their trade. And from the vain expectation of possessing a lucrative branch of commerce, the price of a share rose to 1000 livres.

On the 25th July 1719, the mint was made over to the company, for a consideration of 50,000,000 livres to be paid to the king; and in order to raise that sum, 50,000 new shares, at the rate of 1000 livres each, were directed to be issued. On the 27th August following, the great farms were made over to the Company of the Indies, on their agreeing to pay 3,500,000 livres in advance of rent for them; and on the 31st of the same month, they obtained the general receipt of other branches of the king's revenue. The company now promised an annual dividend of 200 livres on each share, in consequence of which the price rose in the market to 5000 livres each. The company engaging to lend the king to pay off his creditors 1500 millions of livres at 3 per cent. created in September and October 300,000 new shares, rated at 5000 livres each, so that they had now altogether 600,000 shares; but their annual income amounted to 131 millions, which arose as follows, viz. 48 millions interest from the king; 39 millions from the farms, the mint, and the receipt of taxes; and 44 millions from their trade. From so great a revenue

they could well afford to pay more than 200 livres of annual dividend on each share. The inflation, which at this time prevailed in France, raised the price of shares in the market to more than 10,000 livres each, and the original proprietors acquired immense fortunes. But the public had full confidence in the stability of the bank; money was abundant; the agriculture, manufactures, and commerce of the French flourished; plenty displayed itself in the capital, the cities, and provinces; and government were enabled to relieve the people from the burden of 87,000,000 of duties and taxes.

Notwithstanding the general confidence in the stability of the Bank and India company, yet there were individuals who held a different opinion; and they eagerly converted their paper into specie, which they either hoarded up or remitted abroad. This occasioned a constant drain of gold and silver; and specie became so scarce, that there was not a sufficiency left in France for the ordinary purposes of circulation. A run on the bank was now apprehended, and to avert the danger which threatened the whole system, several edicts were passed in January, February, and March 1720, restricting payments in specie to small sums; prohibiting the manufacture of plate without the royal licence; and declaring, that all rents, taxes, and customs, should be paid in notes, the value of which was to remain always invariable, while the standard of the coin was kept in constant fluctuation. But the plan of restriction was carried to its greatest height, by the edict of the 27th February 1720, which prohibited individuals, and secular or religious communities, from having in their possession more than 500 livres in specie, under pain of a heavy fine and confiscation of the sums found in their custody. These measures could not fail to have the effect, to throw an immense sum in specie into the coffers of the bank; and it is said, that betwixt the 27th February and the 1st April 1720, not less than 300 millions of livres were paid in coin into the bank.

The Royal Bank was now incorporated with the Company of the Indies, and the king remained guarantor of the bank notes, of which none were to be fabricated in future, except in virtue of edicts of council. The profits which had been made by the bank since his majesty had taken it into his own hands, in December 1718, were given up to the company; and as they were supposed to be immense, the public entertained a high idea of the company's opulence. At this period, the public credit of France was at its height; but it soon experienced a reverse, that involved thousands in misery and distress.

Cardinal du Bois, and others of the ministry, who envied or detested Mr Law, represented to the regent that it was necessary to equalize the value of the paper currency and the coin, by either raising the denomination of the latter to 130 livres the marc, or reducing the former to one half. This absurd notion prevailed in the council, and it was resolved to diminish the value of the bank notes, and the India Company's *actions*, that a just proportion between them and the coin might be maintained. For that purpose, an edict was issued on the 21st May 1720, ordering that shares in the company should be immediately reduced to 8000 livres; on the 1st July to 7500 livres; on the 1st August to 7000 livres; and so on by 500 livres a month till the 1st December, when they were to remain fixed at 5000 livres. It ordered also that bank notes should be reduced in the pro-

portion as 10 is to 8; but that on the 1st of July they should be farther reduced; those of 10,000 livres to 7500, and so on monthly, at the rate of 500 livres, until the 1st December, when they should remain fixed.

This impolitic and disgraceful measure was accompanied with corresponding consequences. The notes lost all credit, and the whole paper fabric, in a moment, fell to the ground. Mr Law's system was overthrown, and in its ruin involved thousands, who had converted their property into bank currency, on the faith of the declarations of government, which had solemnly engaged, that whatever alterations should take place on the coin, the bank notes should always remain invariable, and be paid in full.

At this time, the amount of notes in circulation were not less than 2,235,085,590 livres, and as they would not pass for any fixed value, the distress of the public became extreme; so much so, that the people were driven almost to despair, and threatened the very existence of the government. To alleviate, in some degree, the calamities, which the regent and his council had so imprudently brought upon the country, the bank, which had been shut on the 27th May, under pretence of examining the accounts, was again opened on the 10th June for the payment of notes of 10 livres; and notes of 100 livres were to be changed into small notes, but only one to be brought by each person coming for that purpose. The 17th July was appointed for the payment of notes of 100 livres; but the concurrence of people who wished to exchange notes was so great, and so many obstructions were thrown in their way, that a scene of riot and confusion took place, which was only suppressed by a military force.

To absorb, however, the immense quantity of paper with which France was deluged, government had recourse to the plan of granting annuities to the holders of bank currency. Accordingly, 25,000,000 of perpetual annuities at the rate of forty years purchase, and 4,000,000 on livres, at twenty-five years purchase, were constituted. Books of accounts current, and transfers of 600,000,000 were opened at the bank, and in August, 8,000,000 more of perpetual annuities, at the rate of fifty years purchase, were issued. By these methods, it was expected that 2000 millions of notes would be retired; but, notwithstanding the discredit of the paper currency, the unfavourable nature of the terms made several people hesitate. It was therefore thought necessary to publish an edict on the 15th of August, that notes of 10,000 and 1000 livres should have no currency, except for the purchase of annuities and bank accounts, or for the supplemental payments directed to be made on the *actions*; and by a subsequent edict, all payments in notes were prohibited on the 1st of November 1720.

Thus terminated Mr Law's celebrated banking system, which, though founded on principles calculated to ensure its stability, could not resist the folly or perfidy of a despotic government. But France had reaped some advantage from its establishment, in her agriculture, her manufactures, and commerce; and the people had in general become more industrious and better acquainted with the principles of trade, in consequence of the abundance of the circulating medium, which this establishment had afforded.

It is unnecessary to pursue our inquiries, as to the banking establishments of the French, through the period of the revolution; as a new and important institu-

tion for that purpose, under the sanction of the Imperial Republic, has superseded all others in France.

The regulations of this bank were decreed by the law of the 24th Germinal, year XII. (1804) and are as follows:

1. The association formed in Paris, under the title of the *Bank of France*, shall have the exclusive privilege of issuing cash notes upon the conditions mentioned hereafter.

2. The capital of the bank shall consist of 45,000 shares, at 1000 francs per share, (1,800,000*l.* sterling, at 25 francs for 20*s.* English) as primitive capital, subject to increase through the medium of *reserved* funds.

3. The bank shares shall be filled up with the name of the holder, and not be made payable to the bearer.

4. The amount of each share shall not be less than 500 francs.

5. The bank shall discount bills of exchange, notes, or bonds. The bank, however, shall not carry on any kind of commerce except in money matters; neither shall it discount any but such bills, &c. as it shall deem good, or conceive real value to have been given for.

6. Discount shall be charged in proportion to the number of days the bills, &c. shall have to run.

7. The being a stockholder shall not be considered as bestowing any particular right to, or exemption from, discount.

8. The annual dividend, computing from the 1st Vendemiaire, 13th year, shall not exceed 6 per cent. and shall be paid half yearly. The benefits over and above the annual dividend shall be converted into funds of reserve in the 5 per cents. consolidated. The dividends of the last six months of the year XI. shall be regulated according to ancient usages of the bank. The dividend for the year XII. shall not exceed 8 per cent.

9. The 5 per cents. consolidated, acquired by the bank, shall be entered in its name, and shall not be sold without its authority during the term of its privilege.

10. The representation of the whole of the stockholders shall be vested in 200 persons from among themselves, who shall form the general assembly of the bank.

11. The 200 stockholders, who shall compose the general assembly, shall be such as the bank shall deem fit for that purpose; and the preference in choosing shall be given to the oldest stockholders.

12. The general assembly shall be convoked each year in Vendemiaire, and shall be obliged to meet on other extraordinary occasions.

13. The members of the general assembly shall assist and vote in person, and shall employ substitutes. Each member shall have but one vote, whatever number of shares he may hold.

14. No person shall be eligible as a member, unless he actually be a citizen of Paris.

15. The affairs of the bank shall be managed by 15 directors, and superintended by three censors, chosen from the body of the stockholders by the general assembly. The censors and directors shall form the general council of the bank.

16. The directors and censors shall be annually changed.

17. Seven directors out of fifteen, and the three censors, shall be manufacturers or merchants who hold bank securities.

18. There shall be formed a discount council, composed of twelve members chosen from such of the

stockholders as are engaged in commerce in Paris. These twelve shall be nominated by the three censors, and shall annually be changed. The members of the council shall manage the discount concerns, and shall have a deliberative voice.

19. The directors, censors, and members of the discount council, who go out of office annually, may be re-elected.

20. The services of the directors, censors, and members, &c. shall be gratuitous.

21. The council shall nominate a central committee, composed of three directors, one of whom shall be named president; and in this character he shall preside over the general assembly, the general council, and all the committees at which it shall be deemed necessary for him to assist.

22. The president shall hold his office for two years. One or other of the two remaining members of the committee shall go out of office annually, but they may be all re-elected.

23. The central committee is especially and exclusively charged with the direction of the whole operations of the bank.

24. It is moreover bound to keep an account of such as partake of the discounts, and to make such alteration in this respect as it shall judge necessary to be made. This statement will serve as a sort of government for the distribution of discount.

25. Those persons who may have cause to complain, relative to the distribution of discount, must apply for redress to the central committee and to the three censors.

26. The censors shall declare the result of their superintendance at such general assembly, and say whether the discount regulations have been properly observed.

27. The actual general council is bound to make the necessary statutes for the internal administration of the banking affairs within a month.

28. The privilege of the bank is to last for 15 years from the 1st Vendemiaire, XII. year.

29. The directors and censors of the bank of France shall preserve their titles, and exercise their functions, during the time fixed by the statutes and regulations.

30. The Caisse d'Escompte du Commerce, the Comptoir Commercial, the Factorerie, and other associations at Paris, which have issued bonds, bills, &c. shall not from the date hereof issue similar or any other bonds, &c. but shall take care to call in all such as are now in circulation, previously to 1st Vendemiaire next.

31. No bank shall be formed in any of the departments unless under the authority of government; and even then shall be restricted to the issuing of notes to a certain amount. The articles 3d, 5th, 6th, 13th, 24th, 25th, shall be applicable to the banks of the departments.

32. No exceptions shall be made to the sums of accounts current in the privileged banks.

33. Judicial actions relative to banks, shall be instituted and carried on in the names of the directors of the bank of France.

34. An annual agreement may be made with privileged banks for the stamping of their notes.

35. And lastly, any persons forging notes similar to those of France or other privileged banks, receiving such notes knowing them to be forged, shall be liable to capital punishment.

The rules or regulations of this bank are well calculated for its security and prosperity; but whether any institution of the kind can flourish in a despotic country, where the funds are liable to be diverted from their original purpose by the influence of power, is extremely questionable. It is well known, that all mercantile associations derive their stability and credit from a strict observance of the rules by which they are constituted, as the confidence of mankind can be firmly placed only on what is known, fixed, and determinate; and there are no establishments which ought to be more inviolable than those of banking companies.

It is universally acknowledged, that arts and manufactures have been brought to great perfection by the division of labour; and it is equally true, that a *circulating medium*, by representing property in all its divisions, enables the community to exchange the products of their industry with ease and facility. As the operations of commerce are therefore not confined to the barter of the *ipsa corpora*, or, the mere exchange of one commodity for another, but can be transacted by the subtlety of an active agent, that occupies little space, yet comprehends value to any supposable amount, the production of the articles of consumption must be greatly multiplied and varied. The comforts, the luxuries, and the enjoyments of mankind are thus increased, and the whole society obtains an addition to its happiness. If such beneficial consequences result from a circulating medium, it will be admitted, that the society which possesses an abundance of it, or the means of augmenting it, by a process that encourages its production, must be wealthy and prosperous; and such is the society of Britain. Our industry, our skill and ingenuity, could not be fully exerted, nor the productions of the arts, manufactures, and commerce of the community generally diffused, without the intervention of a circulating medium, which, representing every species of property, combines the individual exertions of men, and links, in one great chain, their separate efforts for the common happiness of all. The facility of transacting the exchange of one commodity for another, by means of a generally acknowledged representative of value, is exemplified by the following case:—An agriculturist in the north of Scotland may exchange the produce of his labour with that of a Yorkshire manufacturer, by selling a quarter of wheat at home for a bank note, and purchasing cloth with it from a neighbouring haberdasher. The *value* of the wheat, or what is the same thing, a symbol of its value, may be thus conveyed in a letter, whereas, the delivery of the commodity itself might incur an expense equal to its original price. In this case, we find an illustration of the general principle on which commerce depends, as well as a convincing instance of the vast utility of a circulating medium.

Before the discovery of the use of money, as an instrument for ascertaining the comparative value of commodities, the exchange of the produce of one country with that of another must have taken place, by the delivery of the commodities themselves; and even after an imaginary value was attached to the precious metals, their conveyance from one quarter of the world to another must have been attended with great inconveniency, risk, and danger. But when commerce became more general, in consequence of the progress of civilization, and embraced the productions of countries remotely situated, a substitute for money, that could be easily carried, or, if lost, speedily recovered, produced effects,

that united the arts and ingenuity of nations the most distant. Bills of exchange, which were introduced into Europe towards the close of the 12th century, have accordingly effected every purpose that could have been accomplished by an abundance of gold and silver; and they are now the only means of payment among commercial men, excepting in cases, where the precious metals, from particular circumstances, are an article of profitable merchandize. To explain the principle on which depends the importance of a bill of exchange, it is only necessary to recur to daily experience. A trader in London, for example, can pay a cargo of wheat to a merchant in Russia, by transmitting to him a bank of England bill, which would pass in that country for value, from the well founded conviction that it may be ultimately resolved into gold, or into any commodity that gold could purchase. The utility of banks, therefore, arises from their affording a circulating medium representing property, the quantity of which is only limited by the necessity that occasions it, or, in other words, by the demand induced by the diversified operations of commerce. As this substitute for money can be fabricated at little expense, it may be deemed an artificial and inexhaustible mine for supplying the deficiency of the precious metals, or altogether supplanting them as a circulating medium. As gold and silver, however, have so long represented property, the habits of mankind have attached an idea of value to them, which is almost universal; and it is only among polished nations that bank bills are current; but to civilized society, they are of the highest importance, and the invention of the banking system introduced a new æra in the annals of commerce.

The establishment of banking companies in almost every capital city, or populous town in Europe, has produced the happiest effects, by affording the means of promoting and extending agriculture, manufactures, and commerce; but no where has the system been carried to such an extent as in Scotland, in proportion to the industry, riches, and population of the country. In Scotland, banks are properly establishments for deposit, credit, and discount. They embrace a wide field, comprehending the borrowing and lending of money, buying and selling bills of exchange, discounting the promissory notes of individuals, and circulating their own. They advance money without any other security than a bond signed by two or three solvent men; and this constitutes what is called a *CASH ACCOUNT*, which is merely a power to an individual or a company to draw out a specified sum at the rate of 5 per cent. to be again replaced by instalment, for which the same rate of interest is allowed. On this account, a man may operate for life, occasionally drawing and replacing, as his circumstances, or the nature of his business, will admit. Such credits are peculiar to Scotland. In England, a banker pays the drafts of a customer to the extent only of the cash actually deposited in his hands. In this respect, he is merely the keeper of the money of another, as he does not even allow interest for the sums lodged with him.

Scotch banks borrow money at 4 or 5 per cent. interest, payable on demand, which enables them to extend their trade, and to occupy capital that might be otherwise unemployed. They discount drafts on London and other places at distant dates, and promissory notes payable anywhere in Scotland at 3 or 4 months to run, deducting only the legal interest. From this branch of the busi-

ness, they derive considerable advantage, as they receive interest for the notes they issue; but the public are also benefited, for those who convert their bills into currency thus obtain command of their capital, and are again enabled to go to market. But the principal source of emolument to all banks arises from circulation, that is to say, from the number of their notes constantly remaining in the hands of the public. For every month that a one pound note is kept in circulation, the bank gains one penny sterling, because it received the full value of that note at the moment it was issued, and that value bears interest at the rate of 5 per cent. Buying and selling bills of exchange on London, or elsewhere at a distance, form another source of profit to Scotch banks; for they buy drafts in London at 20 or 30 days premium, and sell at 40 or 50 days.

The expense of agency, no doubt, reduces the profits of Scotch banks; but as they never keep gold or silver in their repositories equal to the amount of their notes in circulation, an agent in London, to accept and pay their drafts, is indispensably requisite; for they must be able to give bills on London to all claimants who will not be otherwise satisfied, or to convert their

own drafts into cash in case of urgent demands. Country banks generally establish an agency in London, by investing their capital and borrowed money in the public funds, under the controul of the agent, who is thus secured for the amount of his engagements on account of the bank. The advantage of this plan is, that the bank obtains interest for its capital and borrowed money, and at the same time, in cases of emergency, can convert the whole into cash by the sale of stock. By judicious management, and especially by taking care to purchase a surplus of bills on London, a private bank may be conducted with very little capital in Scotland, where the facility of carrying on the business has induced the erection of many of them; but their operations are beneficial to society at large, and the advantages of an abundant currency are evident, from the growing wealth and prosperity of the country.

* The preceding article leaves nothing to be wished for, as well with regard to the history of the most prominent banking institutions in Europe, as to the correctness of the general view of their operation, and their beneficial influence on industry and commerce. The subject, however, being of great importance, and the diffusion of an accurate knowledge of it highly desirable, we imagine that a short recapitulation of the whole train of ideas, which lead to such a knowledge, will, at this place, not be unwelcome to the American reader.

The happiness of individuals in a civilized state of society, as far as regards their physical condition, depends on the possession, and tranquil enjoyment, of what may be generally termed the *good things* of life. Almost all of these, at least all which the savage has not in common with civilized man, are the result of *labour*. Hence the universal aim of man, in the civilized state, is to labour to the *best advantage*; for it is obvious that he, who, with the same degree of exertion, procures a greater share of the *good things*, or he, to whom the possession of the same share costs less trouble, so far enjoys the better lot.

This aim, to labour to advantage, necessarily led to the *division of labour*; because it is only when the whole business of society is portioned out among the individuals composing it, that the greatest benefit can be derived from individual skill, from experience, capital, machinery, contrivances for the expedition of work, and local position. But, the wants of civilized man being endless, this division of labour could not be reconciled with his personal interests, unless there was an exchange of the commodities produced. Thus division of labour necessarily led to traffic and commerce.

The more extensive this traffic, and commerce, between mankind, the more every individual, every community, every state, every nation, will be able to labour to the *best advantage*; and the greater, (other things

being equal,) will be the mass of happiness enjoyed by the whole.

But as most commodities do not form, like glass-ware, and live-stock, indivisible totals; and as all of them possess *extension*, and *substance*, and are *objects of desire*, in a greater or less degree, the business of society could not have been conducted with convenience, and dispatch, unless *measures* had been invented for degrees of extension, for amount of substance, and for value. Hence have resulted *rules*, *weights*, and *money*. The true end and object of these things—their real utility, is the *dispatch of business*; and this, therefore, is the *true* and *sole criterion*, by which their perfection ought to be tested.

Whether a *yard* be a stick of hickory wood, of ebony, or of iron, or whether no stick at all, but merely a mark on a counter—this may be of some importance to a refractory apprentice, who will have more reason to dread the thing, in its occasional, collateral employment, in one shape than in another, but it is absolutely immaterial with regard to the commercial concerns of the shop. Provided the instrument measures correctly, the rest is of no further consequence, except as far as it may be productive of more or less convenience.

The same holds good with regard to *weights*. The same also holds good with regard to *money*, in its capacity of *measure of value*.

But the same thing which measures value, if of a nature to be easily transferred, and transported, must also be the *best means of exchange*, the most convenient *medium of circulation*. Money has, therefore, been employed for the purpose, and may be justly defined a tool, a contrivance of civilized society, wherewith to measure value, and effect exchanges.

Whether money, therefore, has any value *in itself*, whether as substance, as material, it is an object of desire or not, this, for the purposes of society, which are *dispatch of business*, is as indifferent as the nature of the yard stick. If it measures value, and effects ex-

change, if it *marks a price*, and if it *passes*, it is *good money*. The *best* money is that which performs these functions with the greatest accuracy, with the greatest economy, and with the greatest convenience.

The precious metals were long exclusively employed for the purposes of money, and as they possess a value—that is, are objects of desire, as substance, as metals, as well as in their *capacity of coin*, mankind find it difficult to familiarise themselves to the idea, that these *two* values are *distinct*, and that their combination in coin is *accidental*, but not *essential*. An eagle, as gold, is a thing that may be wrought up, and serve for ornamental purposes; an eagle, as coin, is only the power of commanding in the market as much value as it measures, a power which any other token, measuring the same value, and passing, gives as effectually.

But the precious metals being, in some degree, *scarce*, they cannot be always commanded to the extent which occasions, and the circumstances of society, may require. This inconvenience, as appears from the preceding columns, was strongly felt at Venice, in the middle of the 12th century, and gave first birth to the idea of measuring value, and effecting the circulation of commodities, by means of *credit* instead of *coin*, or, in other words, of establishing a *bank*.

The superiority of bank money over coin, for convenience, economy, safety, and dispatch of business, has, since that period, been felt and acknowledged, wherever it came within the reach of experience, and is, also, theoretically obvious. It is so great, that, *were it not for other considerations*, the use of coin, in every country, ought to be set aside entirely.

But *credit*, when rendered by means of banks the measure of value, and the medium of circulation, may be extorted by *power*, or *corruptly granted* where it is not deserved. It may be abused by the institutions themselves, and the institutions again may be abused by a tyrannical government. This circumstance prevents their *general* introduction, and restricts their use to *well regulated* societies. With these alone they are compatible. Of these they create the prosperity, and constitute a principal ornament, because they are the offspring of prevailing *law* and *morality*, and their attendant *faith*.

Credit, when made to answer the purposes of money, also becomes a sort of *commodity*, the commercial value of which, like that of all other commodities, is liable to be affected by scarcity and abundance, a circumstance much to be regretted. For, as money is the measure of value in all the common concerns of life, its own value should be, as nearly as possible, invariable. A yard, a pound, a dollar, must mean to-day what they meant yesterday and the day before, else all will be confusion. In this respect the measures of extension, and substance, have attained a perfection, which is still wanting in the measure of value. Whatever *material* be employed for this purpose, it must be apt, sometimes inconveniently to accumulate, at other times to be drained off; by either of which occurrences, its character, as measure of value, will be necessarily affected. Gold and silver have been thought less liable to these fluctua-

tions than most other materials, and therefore chiefly have been made the standard of value in almost every civilized country. We need, however, only to compare the quantum of the necessities of life, of which a certain weight of gold, or of silver, gives the command now, with the quantum of which it would have given the command some hundred years ago, in order to convince ourselves that their value is far from being unchangeable.

We should by no means despair that the *unit*, however denominated, of the *ideal* measure of value—*credit*, the amount of which in the market, in the shape of exchangeable commodity is under constant control, might be made, by the banks who give it currency, to bear a much more steady relation to a day's labour, than our dollars, and eagles, and thus become a *superior standard*. But until a proper system to this effect has been devised and perfected; or, like the contrivances of banks and bills of exchange, forced into existence by the pressure of circumstances, it is judicious to hold fast to the standard, under the use of which business has been hitherto tolerably well conducted, and to prevent the excess of the circulating medium of paper, or other tokens of credit, by their *convertibility into coin*.

Whether it is well that all bank paper should be *directly* convertible into coin, is a question of considerable importance. The great convenience derived from banks, by those in immediate relation with them, by their customers, and the prevailing horror of monopoly, seem to forbid, in a country as extensive as ours, the idea of their limitation to a small number. On the other hand, the great multiplicity of banks; the consequently very circumscribed circulation of their notes; and the impossibility, thence resulting, for the general government to exercise any sort of control over the currency of the Union—are great political evils, which, in critical times, may arise to an alarming calamity; and they seem, moreover, to endanger the solidity of the whole system of a paper medium of circulation—a system of such importance to the permanent prosperity of the country, that it cannot be too carefully strengthened against the dangers of adverse contingencies.

We have endeavoured elsewhere to show, that the circulating medium of the country, the banking system, and the financial concerns of government, might, perhaps, be put on an infinitely better footing than that on which they are now placed, by establishing a powerful national institution, guaranteed by the general government, but left, in its details, entirely to the management of individual stockholders, the notes of which should be at all times convertible into coin, whilst payment of the notes of its branches, of the state and of all other banks, when exceeding a certain sum, ought to be demandable only in national notes—so as to give to these a circulation commensurate with the limits of the empire, and render the national mother bank the great repository of metallic treasure. We beg leave to refer to those papers such of the readers as are desirous to pursue the subject further.*

After this short recapitulation of the leading theo-

* See "Thoughts on an improved Financial System for the United States," and "Outlines of a Plan for the regulation of the Circulating Medium," in the 6th number of the *American Review*. Also, "A Letter on the present state of the Currency of Great Britain," in the 4th number of the same work, and "Paragraphs on Banks," 2d edition.

ical ideas with regard to banking, we proceed to some historical details respecting the principal banking institutions on this continent.

The first was the *Bank of North America*. It owes its origin to the vigorous mind and enterprising genius of *Robert Morris*, esq. who conceived the idea of it when superintendent of the public finances, and submitted to congress, in the month of May of the year 1781, the Plan for establishing a National Bank of North America. Agreeable to this plan, the capital stock was to consist of 400,000 dollars, in shares of 400 dollars each, payable in gold and silver, to be increased by new subscriptions from time to time, at the pleasure of the directors. The directors—twelve in number—were to be chosen by the stockholders, and were to be entrusted with the management of the institution. The notes of the bank—payable on demand—to be made a legal tender, in the discharge of duties and taxes, &c. &c.

On the 26th of May, of the same year, congress approved of the plan, and passed several resolutions, by which they pledged themselves to support the proposed institution; to incorporate the subscribers, under the name of “the President, Directors, and Company of the Bank of North America;” to recommend to the several states the prevention of similar establishments, within their respective jurisdictions, during the war; to receive the notes of the institution in payment of taxes, duties, and all other debts, owing to the United States; and to use their influence with the several legislatures to have laws passed, which should make it felony to counterfeit the notes of the bank, &c. (See Journals of Congress, vol. vii. p. 87.)

After this, subscriptions were immediately opened, and filled, during the summer and autumn of the same year. In November directors were chosen. In December congress, conformably to their previous resolves, passed an ordinance which created the subscribers to the bank a corporation *for ever*, under the title of “The President, Directors, and Company of the Bank of North America.” The original features of the plan proposed were preserved, but the bank was restricted from holding property exceeding the amount of 10,000,000 of dollars.

The institution commenced its operations in the month of January following, and *Robert Morris*, who may be justly styled the father of the system of credit and paper circulation in this country, succeeded in securing to it the good will and confidence of the people at large, by various judicious measures, of which a circular letter, addressed to the governors of the several states, explaining the object of the institution, and the certain advantages to be derived from it, was not the least effectual.

Thus the first bank on this continent came into existence, and such was its happy and immediate influence on the public finances, and on commercial concerns in general, that it may be justly doubted whether, without its seasonable aid, the revolutionary struggle for independence could have been brought at all to a satisfactory termination. The United States, for several years, were constantly indebted to the bank to a larger amount than the stock they owned; nor could the various devices for creating a revenue have answered their end, or the army have been fed and clothed, or any degree of order and punctuality maintained in the dispatch of pub-

lic affairs, but for the great facility in the management of business, and the restoration of confidence, which were created by this institution.

The sense of the great utility of the bank was so universal, that Massachusetts and Pennsylvania corroborated the ordinances of congress by additional charters; and Rhode Island, Connecticut, and Delaware, passed laws for the purpose of preventing the counterfeiting of its notes, and extending their circulation. Yet, when peace had been concluded, and the pressure of the times was over, there were not wanting those, who viewed the prosperous state of the affairs of the bank with a jealous eye, and conjured up imaginary fears of an overbearing oppression, an alarming foreign influence, and fictitious credit from temporary punctuality;—of a created scarcity of specie, possible commercial convulsions from the stopping of discounts, partial favours, and the comparative disadvantages, under which distant traders laboured.—As if, in a moral community, the bare possibility of abuse could ever furnish a good argument against the decided utility of a thing; or, as if a benefit were to be relinquished because all cannot be benefitted alike.—And so effectually were these objections against the institution urged, that, on the 13th of September 1785, the legislature of Pennsylvania actually repealed their charter.

The repeal was persevered in by the succeeding legislature, notwithstanding innumerable petitions to the contrary, and vast efforts to enlighten their proceedings. The bank, however, continued its usual operations under the charter from congress, and in the enjoyment of corporate rights, which, it was presumed, could not be arbitrarily wrested from them, after having once been legally bestowed.

The legislature which met in December 1786, at last thought proper to renew the charter of the bank, and passed an act to that effect on the 17th of March 1787, by which, however, the term of the charter was limited to fourteen years, and the capacity of the corporate body, of holding property, restricted to two millions of dollars. The same charter was extended for the term of fourteen years more by an act passed on the 20th of March 1799.

The capital of this bank has been from time to time increased. It divides, most generally, 12 per cent. on the original price of the shares.

Bank of the United States.—This institution, though no longer existing, has rendered to government, and to the community at large, so many essential services, that we think ourselves obliged to bestow, under this head, a few lines on the history of its origin, and termination.

The idea of it was conceived, immediately after the adoption of the present Constitution, by *Alexander Hamilton*, Esq., then secretary of the treasury. The acute intellect and enlarged mind of this man caused him to master every subject to which his attention was directed, and to embrace it in all its details, and consequences, whether immediate or remote. It had not escaped him, that the work of the Revolution would remain unfinished, without a solemn compact, which should give to the new-born political society consistency and shape, and unite its wide spread members into a well organized Commonwealth. His efforts, therefore,—as his writings testify—had been directed towards effecting the formation of a constitution, and causing it

to be adopted. But, when this was attained, he perceived further, that in order to give permanency to the new fabric, it was necessary to render it respected abroad, and to strengthen it by the support of self-interest at home; he perceived, that it was necessary to raise the edifice of *public credit*, and that this could only be attempted with success, by raising it on the basis of *justice and good faith*.—This required that the general government should acknowledge the debts contracted during the revolutionary struggle, make provision for the regular discharge of the accruing interest, and for the ultimate payment of the principal itself. They were consequently *funded*. A system of revenue was created to meet the future expenditures; and nothing could be happier than the further idea of establishing a NATIONAL BANK, the stock of which was chiefly to consist in *public securities*, in order to procure at once to those securities a great market value, give precision and method to the fiscal operations of the new government, and blend its stability with the comforts of individual existence. It would also have the advantage of turning credit into capital, and enable the country to procure with ease, from abroad, the innumerable things which were wanted to start with vigour in the career of industry, though nearly exhausted with the efforts to attain independence.

The plan of such a bank was therefore submitted to Congress on the 13th of December 1790. It was opposed in Congress by the party, then in the minority, but who have since come into power, chiefly on the ground of the presumed *unconstitutionality* of the measure proposed. The power of creating a bank, or any corporate body whatever, not having been expressly delegated to Congress, it was contended that no such power was possessed.—The *cabinet* was divided on the question, as well as the *public councils*. The then secretary of state, in particular, argued, that, though the constitution, in a summary manner, granted to Congress power to pass such laws, as were *necessary* to carry the *specified powers* into effect, yet this clause could only be considered as applicable to acts, in justification of which there could be pleaded an *absolute, paramount, and irresistible* necessity, not to those, which, like the bank proposed would only rest on the grounds of *expediency, superior convenience, precedent, and general usefulness*.

The manly understanding, however, of the secretary of the treasury, and the practical wisdom of the august chief, then at the head of the government, could not be swayed by grammatical considerations so futile. The former investigated the question, and refuted the pretended constitutional objection with a force of reasoning, which could not fail to remove all doubts on the subject from every sound and unprejudiced mind;* and the latter, consequently, gave his sanction to the act of Congress, incorporating the bank, which passed into a law on the 25th of February of the year following.

Agreeable to this law, the capital stock of the bank of the United States was limited to 10,000,000 of dollars, divided into 25,000,000 shares, of 400 dollars each, payable—one fourth in gold and silver, and three fourths in public securities, bearing an interest of six, and three per cent. The corporation were restricted from contracting debts beyond the amount of their capital, and from holding property, exceeding the value of

15,000,000 of dollars, or real estate, more than necessary for the convenient transacting of their business. The affairs of the bank were to be managed by twenty-four directors, to be elected by the stock holders. Only citizens of the United States, and stockholders, were eligible as such. Only three fourths of their number could be re-elected every succeeding year; and several more regulations were contained in the charter, generally well calculated to guard against any political dangers from this national establishment, to extend its usefulness, and confirm its solidity. The duration of the bank was limited to the 4th of March 1811.

The subscriptions were filled as soon as opened. The government—conformably to the right reserved in the charter, subscribed 5000 shares, or two millions of dollars, and the bank went into immediate operation.

The dividends of the bank—made semiannually—generally amounted to four per cent. Its stock—a great proportion of which was held in Europe—soon rose considerably above par, and the institution proved *always convenient*, on some occasions *eminently useful* to the government, and not less beneficial to the public at large.

Yet, when the period of the termination of its charter arrived, and the stockholders applied to congress for a renewal of it, the same objection of unconstitutionality, which had been successfully combatted twenty years before, was again revived. The institution had become the more invidious to the party in power, for having been, at its very origin, unsuccessfully opposed by their principal leader—an opposition, which, perhaps even then, arose from the desire of signaling a system of political principles, and measures, different from those which were adopted. When the subject came now again under discussion, the force of sound argument, the considerations of general usefulness, and the unquestionable fiscal expediency of the renewal of the charter, could not be expected to avail against unfriendly sentiments of such long standing. An impulse was given accordingly; the renewal of the charter refused, and the institution dissolved.

The public prosperity might have received a severe shock, and government itself been exposed to difficulties and embarrassments much more serious than those under which it must now necessarily labour, from the want of a national bank, if the same course of deliberate prudence, which has marked the conduct of the late Bank of the United States throughout, had not been also pursued in their mode of withdrawing from business. But they proceeded in this work so slowly, and acted towards individual debtors, and towards other banks on which they had claims, with so much liberal forbearance, that time was gained to supply the public with the circulating medium of *new bank credits*, in lieu of those to be withdrawn. A conduct which was moreover dictated by the interests of the expiring institution itself, and singularly favoured by the general stagnation of commerce at the period when it took place.

Besides the two banks we have mentioned, many others, the number of which is daily increasing, have been established, and continue to exist, throughout the United States. The general features of their charters are the same. They transact business on the same plan, being all banks of deposit and discount, issuing notes, payable in coin, on demand, but serving princ-

* See Works of Alexander Hamilton, vol. v.

pally to settle commercial transactions between their respective customers, by means of *transfers from account to account*, which transfers are effected by debiting, and giving credit for *checks*; a circumstance which, in the general view of their operation, should never be lost sight of. We believe that the following table, exhibiting at one view the names of those most deserving of notice, the time of their institution, and the amount of their capital, will be deemed, by most of the readers, sufficient for their information. BOLLMAN.

BANKOK, one of the chief towns of the kingdom of Siam, situated in an island about seven leagues from the sea, near the mouth of the river Menam. In the end of the 17th century, the French had an establishment in Bankok, consisting of two companies of 40 men each, in a square fort on the other side of the river; but they abandoned it in 1685. The vessels of all the nations that trade with Siam are obliged to pay duty here, and to give an account of their cargo and crew. The passport which they receive from the custom-house officer is shewn at a small village called Canon-Bante-nan, which is about an hour's journey from Julia; and if there appears to be no fraud, they are permitted to trade in every part of the kingdom. (j)

BANKRUPTCY, in its more general and extended sense, may be defined insolvency, actual or presumed, followed by some open and public act, denoting that the insolvency is irremediable. He is a bankrupt, "*Qui fortune vitio vel suo, vel partim fortuna partim suo vitio, non solvendo factus, foro cessit.*" Cicero, 2d Philip.

In the early ages of a state, the law of bankruptcy is uniformly cruel and oppressive. The unfortunate debtor is regarded as a criminal, without distinguishing whether his inability has arisen from culpability or from misfortune; and the law looks merely to the interest of the creditor, without paying any regard to the feelings or to the future comfort of the debtor. The severity of the Roman laws against debtors in the infancy of the republic, and the oppression of creditors, which occasioned so many popular insurrections and so many secessions to the *Mons Sacer*, are known to every one. As states advance in civilization, and as commerce becomes more extended, less illiberal notions prevail, and the innocent trader, reduced to bankruptcy by misfortune, becomes an object of compassion rather than of severity. Creditors too begin to see, that it is for the public interest that the funds of the bankrupt should belong to the creditors at large, instead of being left to be scrambled for by the diligence of individuals; and through the frequency of failures which attends the growth of commerce, the principles of the bankrupt law are examined and matured into a regular system. The great fundamental principle upon which every code of bankrupt law must rest is, that from the moment of the failure, the funds of the bankrupt become the common property of his creditors at large, and are no longer liable to be disposed of by himself, or to be attached by individual creditors. The perfection of every code must depend upon the manner in which this principle is carried into effect, by the adoption of a simple, economical and speedy mode of distributing the common fund.

It was not till a very late period that the bankrupt law of Scotland assumed a systematic form. We, indeed, at an early date, adopted from the Roman law the mild remedy of the *cessio bonorum*, by which an honest though insolvent debtor, who was willing to surrender all his effects to his creditors, escaped the hardship of a long imprisonment; and by the statutes 1621, c. 18, and 1696, v. 5, attempts were made to prevent insolvent debtors from granting any deeds in fraud of their creditors. By this last statute, bankruptcy was accurately defined, and its date being fixed, a presumption of law was established against all deeds granted within 60 days of it, in favour of prior creditors. Still, however, no plan was devised for a general distribution of the bankrupt's effects. The creditors were left to proceed with their in-

dividual diligence as they best could, and the maxim of law being "*Jus civile vigilantibus scriptum est,*" an unfortunate debtor was, on the first suspicion of insolvency, overpowered with a torrent of diligence, which even the best credit could scarcely withstand. The great increase of commerce during the last century, and the consequent frequency of failures, imperiously called for an alteration of this system, and after a variety of experiments, the plan which is now in execution was adopted, by the statute 33 Geo. III. c. 74. This statute, though merely temporary and experimental, has been repeatedly renewed; and the system which it establishes, although perhaps still capable of considerable improvement, is admitted on all hands to possess great and peculiar excellencies.

By the statute 1696, c. v. any person may be rendered a bankrupt who is at the time in Scotland, and subject to its laws. The effect of this bankruptcy against persons, who are not traders, is only such as to enable creditors to challenge undue preferences, and to follow forth the ordinary processes for attachment and distribution of the funds. But by the 33d Geo. III., a new process called sequestration is introduced, by which the whole estate of a bankrupt *trader* is adjudged from him, and vested in a trustee for the creditors at large. The statute describes the persons liable to bankruptcy by sequestration, to be "in general, any person, who, either for himself, or as agent or factor for others, seeks his living by buying and selling, or by the workmanship of goods or commodities." All persons capable of entering into trade are liable to sequestration; peers and others having privilege of parliament; unmarried women and widows coming under the description, and also married women who carry on trade or merchandise independent of their husbands. Trading companies may also be sequestrated. The statute makes the following exceptions: holders of India stock, or stock in any of the banks established by public authority, or in the Friendly Insurance Company, the Forth and Clyde navigation, or other inland navigations, or the British fisheries, common labourers or workmen for hire, landholders and tenants of land, or husbandmen, if such persons be not otherwise *bona fide* under the foregoing description. A grazier, though he also be a tenant, may be sequestrated, if he deals in cattle not the produce of, nor grazed upon, his own farm. A foreigner who has traded to Scotland, or a Scotsman domiciled abroad, cannot be sequestrated, although found in Scotland.

Such are the persons liable to sequestration. It is next to be considered, from what acts bankruptcy is inferred, so as to authorise this process. Where the debtor himself concurs, no proof of bankruptcy is necessary. Where he does not concur, the creditor must shew that certain steps of diligence have been taken against him. These are, That the debtor shall be under diligence by horning and caption for debt, and shall either, in virtue thereof, be imprisoned, or retire to a sanctuary, or fly or abscond for his personal safety, or defend his person by force; or being out of Scotland, and not liable to be imprisoned, by reason of privilege or personal protection, shall be under diligence by charge of horning, attended with arrestment not loosed, or pointing of any part of his moveables, or decree of adjudication of any part of his estate, for payment or security of debt, at the instance of any creditor.

When a person comes under the description of the

BANKRUPTCY.

statute, and has been rendered bankrupt by the use of any of the diligence just mentioned, any one creditor, to the amount of 100*l.*, or two creditors to the amount of 150*l.*, or three or more to the amount of 200*l.*, either with or without the concurrence of the bankrupt, may apply by summary petition to the court of session for a sequestration. Where the bankrupt concurs, sequestration is immediately awarded; where he does not concur, a warrant is granted for serving the petition upon him, and if he does not appear, and shew cause to the contrary, sequestration is awarded against him. The court at the same time appoints the creditors to meet and choose an interim factor for managing the estate, and also appoints a subsequent meeting for choosing a trustee. When the factor is chosen, he has power to take possession of the whole estate, books, and vouchers of the bankrupt, who is bound to grant powers of attorney, for recovering any effects he may have abroad. At the next meeting ordered by the court, which must be within six weeks, and not less than four of the first deliverance on the petition for sequestration, the creditors who have produced their grounds of debt, and affidavits to the verity, proceed to elect a trustee, to whom the estate may be assigned for the general behoof. This trustee is to be chosen by a majority of the creditors in number and value. Two trustees may be chosen to act, the one failing, the other, but one only can act at the same time. At this meeting the bankrupt must exhibit a state of his affairs, and the interim factor must also produce an account of his management.

The trustee must find security to the creditors for his faithful management; after which the Court of Session, upon application, will confirm his nomination, and he is then authorised to take possession of and uplift the estate of the bankrupt, and to exoner the interim factor. The court at the same time appoints the bankrupt to grant a regular conveyance of his whole estate to the trustee, under the pain of fraudulent bankruptcy, and failing his doing so, the court may commit him to prison. Whether such conveyance be granted or not, the whole estate is adjudged by the court to be vested in the trustee for behoof of the creditors.

The trustee must, within eight days of his appointment, apply to the sheriff to fix two days for the examination of the bankrupt, upon all matters relating to his affairs. The bankrupt's wife and others of his family, and any other person connected with his affairs, may also be examined. At the last of these examinations, the bankrupt must take an oath that he has exhibited a full state of his affairs; and failing his doing so, he shall be guilty of the crime of fraudulent bankruptcy, and punished accordingly, and rendered infamous. The trustee may apply to the court to grant protections to the bankrupt from diligence to enable him to attend examinations, and to assist in recovering his estate; and while so employed, the creditors may give him an allowance for his support, not exceeding two guineas a week.

A general meeting of the creditors is to be held the first lawful day after the last examination of the bankrupt, for the purpose of instructing the trustee as to the management of the estate. At this meeting three commissioners are to be chosen to audit the accounts of the trustee, to fix the commission to which he shall be intitled, and to advise and concur with him in compromises and submissions as to the bankrupt's estate.

It is the duty of the trustee to recover and convert into cash, as soon as possible, the estate of the bankrupt, which shall be a fund of division among those who were creditors prior to the sequestration. All preferences or conveyances in security of prior debts, which have been granted by the bankrupt to prior creditors within sixty days of the application for sequestration are presumed to have been fraudulent, and are liable to be reduced; and all arrestments and poindings used by individual creditors, within the same period, are void, and give no preference, except that the *bona fide* arrester or poinder is entitled to retain his expenses of diligence, and ten per cent. more on the price or appraised value. All *bona fide* transactions with the bankrupt in the buying and selling of goods, and paying or receiving of money, previous to the sequestration, are safe from challenge.

The trustee must keep regular accounts, and lodge the money recovered in a bank; and at the end of twelve months from the date of the first deliverance, after due advertisement, a dividend shall be paid to those creditors who have produced their grounds of debt and affidavits. When the term of payment of any debt is not arrived, a proportional discount shall be made, and the debt ranked accordingly. Where a debt is contingent, a dividend corresponding to the debt shall be set aside and deposited in the bank until the contingency be declared.

At the end of eighteen months a second dividend shall be made; and in like manner, dividends at the end of every six months, till the whole funds be divided. But at the expiry of a year and a half from the sequestration, four-fifths of the creditors may order the whole outstanding debts, &c. belonging to the estate to be sold, for the purpose of making a final division.

After the second dividend, the bankrupt, with concurrence of the trustee, and four-fifths of the creditors in number and value, may apply to the court, who are authorised to grant him a final discharge of all debts contracted prior to the sequestration, if cause be not shewn to the contrary.

As it is sometimes for the advantage of all parties to settle by composition, the statute declares, that the bankrupt may, at the meeting after his second examination, offer to settle by composition; and if this offer is approved of by nine-tenths of the creditors present, another meeting shall be called to consider of it; and if at this second meeting nine-tenths of the creditors approve of the offer, a report of the proceedings shall be laid before the court; and if it shall appear that the offer is reasonable, and has been assented to by nine-tenths in number and value of the whole creditors who have produced grounds of debt, the proceedings in the sequestration shall cease, and the court shall declare the trustee exonerated, and the bankrupt discharged, except as to the payment of the composition.

Such are the general outlines of the law of bankruptcy in Scotland. It resembles that of England in some of its general features, though there is a strong and marked distinction betwixt the two systems in many particulars.

In England *traders* only can be made bankrupt. The effects of every other description of persons are left to the remedies of common law, and to be attached and carried off by the diligence of individual creditors.

Certain acts are defined by the different statutes, as marks of bankruptcy, some of which are of an ambiguous

ous and some of a secret nature, such as the debtor "beginning to keep house," so as not to be seen or spoken to by his creditors. The commission of any one of these acts invalidates all the debtor's future transactions, and entitles a creditor to a certain extent to apply for a commission of bankruptcy, which is immediately granted of course, by the Lord Chancellor, vesting the bankrupt's estate in certain commissioners, who are empowered to lock up his shop, and to order his person into custody to undergo the necessary examinations. As this commission is granted without the knowledge of the bankrupt, and is meant to come suddenly upon him, certain precautions are used to prevent its being maliciously sued out.

The commissioners take proof of the bankruptcy, and of the debtor's being a trader, and appoint three meetings to be advertised. At these meetings the debts are proved; and at one of them assignees are chosen, in whom the estate is vested for behoof of the creditors. At the third meeting at farthest, the bankrupt must surrender himself, and afterwards conform to the statutes in all respects, under pain of death.

The bankrupt, and those connected with him, are to be examined as to his affairs; and if their answers appear unsatisfactory, the commissioners may commit them to prison till they submit and give satisfaction.

The whole estate of the bankrupt is vested in the assignees, as it stood in his person when the first act of bankruptcy was committed. After that date, therefore, all his transactions are void and null. It is, however now provided by Sir Samuel Romilly's bill, 46 Geo. III. 135. that all conveyances, all payments by and to, and all contracts and dealings by and with a bankrupt, made more than two calendar months before the date of the commission, shall be valid, notwithstanding any prior act of bankruptcy, if the person so dealing had not at the time any notice of such prior act. It was provided by 19 Geo. II. c. 32. that no money paid by a bankrupt to a *bona fide* real creditor in the course of trade, even after an act of bankruptcy, should be liable to be refunded.

When the assignees have recovered all they can, they must after four, and within twelve months, give notice of a meeting for a dividend. The commissioners then direct the dividend to be issued at so much a pound.

Within eighteen months from issuing the commission, a second and final dividend is ordered, if there be any thing remaining; and if there be a surplus after all the debts are paid, it belongs to the bankrupt.

If the bankrupt conform in all respects to the statutes, and if the creditors, or four-fifths of them in number and value, will sign a certificate to that purport, the commissioners are to authenticate the same, and transmit it to the Lord Chancellor, who, upon oath made by the bankrupt, that it was obtained without fraud, may allow the same, or disallow it on cause shewn by any creditor. If it is allowed, the bankrupt is entitled to an allowance out of his effects to put him in a way of industry. This allowance is proportioned to the amount of the dividend on his estate, but must never exceed 300*l.* The bankrupt is also, by his certificate, discharged forever from all claims for any debts which were proved or provable under the commission.

When a person has obtained a certificate, and becomes bankrupt a second time, unless he shall pay fifteen shillings a pound, he shall only be indemnified as

to confinement of his body; but his future estate shall be liable to his prior creditors.

Such is the law of England regarding traders. All other persons remain subject to the common law, both as to their person and effects. They are liable to perpetual imprisonment, unless relieved by the insolvent acts occasionally past, or by the provisions of what is called the Lords' Act. By this statute it is provided, that a debtor incarcerated for a debt under 300*l.* may petition the courts for liberation, which will be granted on conveying to his creditors all his effects. Had the enactment ended here, it would have been indeed a most salutary provision, equal in kind, though not in extent, to the Scots process of *cessio bonorum*; but it goes on to declare, that if the incarcerating creditor shall object to the liberation, and shall find security for an allowance to the debtor, not exceeding two shillings and four-pence weekly, he may detain him in prison. See Bell's *Commentaries on the Law of Scotland in relation to Bankruptcy*; and Cooke and Cullen's *Treatise on the Bankrupt Law of England.* (v)*

* By the constitution of the United States, Art. I. Sect. 8. the congress is empowered "to establish uniform laws on the subject of bankruptcies throughout the United States." They exercised this power in the year 1800, when they passed a general bankrupt law on the model of the British statutes. It was limited to five years, and was suffered to expire by its own limitation. Since that time, some laud attempts have been made in congress again to legislate upon that subject, but without effect; bankrupt laws being highly unpopular in the agricultural states, though they are much wished for in those that are in a great degree commercial. It is generally understood that the power of enacting laws of this description is vested *exclusively* in the national legislature, and that the individual states have no right to interfere in this branch of legislation. There are, however, those who are of a contrary opinion, but their sentiment does not seem generally to prevail. Hence no attempt has succeeded in any of the states to make a *bankrupt law*, properly so called, that is to say, one which is restricted in its operation to merchants and traders, or to those who earn their livelihood by buying and selling. But the same object has sometimes been obtained by *insolvent laws*, differing from bankrupt laws in nothing else than their general operation. There is one in the state of Maryland, by which every debtor complying with certain requisites, and delivering up bona fide all his property for the benefit of his creditors, may be discharged entirely from his debts by a decree or order of the chancellor of the state. A law similar in its operation was enacted by the legislature of Pennsylvania at their last session, but although its duration was extended to three years, it was not suffered to live more than nine months, and has lately been repealed. In the state of New York, the experiment has succeeded better, and since the year 1801, a system of insolvent laws has been established there, which goes to the extinguishment of the party's debts, not merely to the discharge of his body from imprisonment. We do not find any such law in the code of the highly commercial state of Massachusetts; in that, and most of the other states of the Union, the insolvent laws are framed on the model of the English *Lords' acts*, and on the principle of the

BANKSIA, a genus of plants of the class Tetradria, and order Monogynia. See **BOTANY**. (*w*)

BANNERETS, an order of knights, next in dignity to the barons, and entitled to lead their vassals to battle at the royal summons, under their own banner or flag. By this privilege they were distinguished from the knights bachelors, who were obliged to march under the banner of a superior. The origin of the *name* seems abundantly simple, being obviously no other than banner, a square flag; and this etymology is supported by all the other appellations by which the bannerets were distinguished, such as *militēs vexilliferi*, *vexillarii*, *bannerarii*, &c. But the origin of the *order*, like every thing uncertain, has given rise to much controversy among antiquarians. Some contend that this dignity first originated in France; while others assign that honour to Brittany, and others to England. Those who are of the last opinion trace the order of bannerets to Conan, lieutenant of Maximus, who commanded the Roman forces in England under the reign of Gratian. Revolting from his government, say they, he portioned out England into forty cantons, over which he appointed forty knights, with power to assemble, when necessary, under their own banners, as many fighting men as they could muster in their several districts. Without pretending to decide as to the origin of the order, we can say, with sufficient certainty, when it expired; for the last knight banneret was Sir John Smith, who was invested with that dignity by Charles I. after the battle of Edgehill, as a reward for his bravery in rescuing the royal standard from the rebels.

In feudal times none could obtain the dignity of knight banneret, except gentlemen of family, whose property enabled them to bring into the field fifty men at arms, with the suitable complement of archers and crossbowmen, amounting in all to one hundred. This honour was in general conferred on those who had distinguished themselves by their valour in battle. The king, at the head of his victorious army, and surrounded by all his nobles and field officers, summoned the hero to repair to the royal standard, which was displayed on purpose to receive him. He was conducted to his sove-

reign by two knights, or men at arms, of approved bravery, bearing in his hand his pennon, or guidon of arms, and preceded by two heralds, who proclaimed his gallant exploits. When he came into the royal presence, the king desired him to advance his banneret, and commanded the ends of his pennon to be torn off, which, being thus made square, was converted into a banner. Martial music attended him as he returned to his tent, to which he was accompanied by many of the nobility and principal officers, for whom a sumptuous banquet was prepared. This honour, intended as the peculiar reward of personal gallantry, died with the individual who had earned it; and neither the title nor supporters of the knights bannerets were hereditary. In the 28th of Edward I. a knight banneret had four shillings of daily pay, and his diet at court; and was entitled to take precedence of the younger sons of viscounts and barons. (*u*)

BANNOCKBURN, a small rivulet about three miles from Stirling, on the road to Edinburgh, celebrated for a great battle fought on its banks between the English and Scots armies, in the reign of Edward II.

Robert Bruce, grandson of that Bruce who was Baliol's competitor for the crown of Scotland, had resolved at once to rescue his country from the thralldom into which it had been reduced by the first Edward, and to vindicate his own claim to the throne, now vacant by the demise of John Baliol. The minds of the Scots people had been entirely alienated from that monarch by his pusillanimous submission to Edward, and his desertion of the rights and interests of his own subjects; and his son, a prisoner and an exile, was in no condition to revive the claims of his family, now generally abandoned. The escape of Bruce from the English court, to which he had accompanied Edward I. after his victorious expedition into Scotland, restored to new energy the drooping spirits of his countrymen; and the latent indignation with which they bore the tyranny of the English monarch, now burst forth in the avowed resolution to regain their national independence, or to perish in the attempt. The English were attacked in all quarters; many of their garrisons were reduced; and the authority of Bruce being universally acknowledged, he was solemnly crowned and inaugurated as king of Scotland. But his resources were too slender to support him against such an antagonist as Edward. An immense army was speedily sent against him; and a furious conflict took place, in which Bruce, after displaying the most heroic valour, was overpowered by the superior numbers of his enemies, and forced to take refuge, with a few attendants, in the Western Isles. While Edward was hastening with an overwhelming force to complete the final subjugation of the Scots, and to deprive them of all power of future revolt, he was seized with a mortal distemper at Carlisle; and with his last breath enjoined his son to make the reduction of Scotland the first and principal enterprise of his reign. The death of this warlike monarch, and the weakness of his successor, once more restored the hopes of the Scottish nation; and Robert, who had already left his fastuesses, and gained some important advantages, soon saw his standard surrounded with a band of faithful adherents, burning with revenge against their English oppressors, and united in the resolution to conquer or die. In a short time the English were driven from all their strong holds, except the castles of Stirling, Berwick, and Dunbar; even the frontier provinces

Roman *cessio bonorum*, and effect nothing more than the discharge of the debtor's person from imprisonment, on making a fair surrender of his estate.

From the various experiments which have been made on this subject in the different states, we are apt to believe that the true principle, that which is really suited to the state and circumstances of the country, has not yet been discovered. The machinery of the English bankrupt law appears too complicated, and its uniform effect, to discharge the debtor absolutely, in every case where fraud is not shown, appears, in our opinion, a coarse manner of cutting the knot, which the object of similar laws should be to untie. In this country, bankrupt laws ought to be simple, and calculated to produce the most beneficial effects, both to the debtor and the creditors, according to the circumstances of each case. But this is not the place to enter into a further explanation of our ideas upon this important topic. The object of these notes is to convey information of matters of fact, and not to discuss at large any particular system of legislation. Du Ponceau.

of England were ravaged by the triumphant Scots; and Edward, roused at length from his lethargy, determined to muster the whole force of his kingdom, and, by one decisive blow, to quell for ever a people whom he found such inveterate and troublesome enemies. For this grand enterprise troops were even enlisted in Flanders and other foreign countries: his military vassals in Gascony, Ireland, and Wales, were summoned to repair to the royal standard; and the whole military force of England was commanded to assemble, on a stated day, at Newcastle upon Tyne. At length, on the 18th of June 1314, he began to march from Berwick, with an army of more than a hundred thousand men; followed by an incredible train of waggons, loaded with all sorts of provisions. Scotland had been so much exhausted by its recent wars, that Robert, with all his efforts, could not bring into the field more than thirty thousand men; but they were men of tried valour, inured to all the hardships and vicissitudes of war, and headed by a prince, whose undaunted courage was seconded by the cool self-command and consummate skill of an experienced general. The castle of Stirling had for some time been invested by Edward Bruce; and the governor, Philip de Mowbray, after a gallant defence, was compelled to capitulate, and promised to open the gates of the castle on a certain day, if he should not be relieved before that time by an English army. Aware, then, that Edward would advance immediately towards Stirling, Robert determined to intercept him on his march; and fixed upon a most advantageous position, where he waited to give him battle. He had a hill on his right hand, a morass on his left, and a rivulet in front. As the English were greatly superior to him in cavalry, he employed a very ingenious stratagem to deprive them of this advantage. He commanded deep pits to be dug along the banks of the rivulet, in which were fixed sharp pointed stakes; and the whole was carefully covered over with turf and rushes. On the evening of the 24th of June, the English arrived on the opposite bank of the river; and the two armies, fired with all the rancour of national animosity, rushed immediately to battle. A smart conflict ensued between two bodies of cavalry. That of the Scots was headed by Robert in person, who, engaging in close combat with Henry de Bohun, a gentleman of the family of Hereford, with one stroke of his battle-axe cleft his adversary to the chin. The English horse fled with precipitation; and the Scots, exulting in the valour of their monarch, regarded the favourable result of this encounter as a presage of a more complete victory.

Darkness gave a short respite from hostilities; and never was suspense more interesting than that in which the armies were now placed. The English, elated with former victories, and exasperated by the least appearance of defeat from a people whom they had already considered as subdued, longed eagerly for a combat which was to annihilate the power of their enemies. The Scots saw their independence, and even their existence as a nation, depending on the issue of a single battle; and undaunted by the gigantic power of their enemy, were determined to restore the liberty and the glory of their country, or not to survive its fall. The night, short as it is at that season of the year, appeared extremely tedious to the impatience of the combatants. At break of day Edward drew out his army, and advanced against the Scots. His nephew, the Earl of Gloucester, who commanded the left wing of cavalry, impelled by the

ardour of youth, and disputing the post of honour with the Earl of Hereford, rushed impetuously to the attack, and fell among the covered pits which Bruce had prepared on the bank of the river. Gloucester himself was dismounted and slain; his cavalry were thrown into disorder; and Sir James Douglas, who commanded the Scottish body of horse, giving them no time to recover from their consternation, drove them off the field with great slaughter. The infantry, alarmed by this unfortunate commencement of the action, and afraid of some similar stratagem against themselves, were yet hesitating to advance, when they perceived another army marching slowly along the heights, as if with the intention of surrounding them. This was a number of waggons and sumpter boys, whom Robert had provided with military standards, so as to give them at a distance the appearance of a large army. The stratagem succeeded: the English, distracted by various fears, threw down their arms and fled; the slaughter was prodigious; and as they were at least eighty miles from any place of safety, very few of them would have escaped, had not the Scots returned from the pursuit to seize on the rich spoil of the English camp. Various accounts are given of the number slain in this decisive battle. Some of the Scottish historians assure us that fifty thousand English perished in the action, or were destroyed in flight; and, according to the most moderate calculations, the number of captives amounted to 154 lords and knights, 700 gentlemen, and 10,000 common soldiers. During the whole of the engagement Edward shewed no want of personal bravery, and was with difficulty persuaded to quit the field. He was closely pursued by Sir James Douglas, who was eager to revenge the wrongs of his family; and narrowly escaped by reaching Dunbar, whose gates were opened to him by the Earl of March; and from thence he took shipping for Berwick. The loss of the Scots, too, was by no means inconsiderable; for even their own writers allow that 4000 of them fell, among whom there were only two of equestrian rank.

Such was the great battle of Bannockburn, which completely secured the independence of Scotland, established the family of Bruce on the throne, and inspired the English with such a dread of Scottish valour, that for many years they never would venture to oppose any number of Scotsmen in the field. Robert, availing himself of his present advantage, marched directly to England, and ravaged, without opposition, all the northern counties, besieged Carlisle, and took Berwick by assault. In return for some of his noble prisoners, he received his wife, his daughter, and sister, and all the Scottish nobles and gentlemen, who had been prisoners since the reign of Edward I.; the liberty of his other captives was purchased at immense ransoms, which were a new accession of wealth to the kingdom. See Hume's *England*; Henry's *Britain*, vol. vii. p. 139—144. Buchanan's *Rerum Scotticarum Historia*, cap. 97. (k)

BANTAM, a seaport town, and the capital of a kingdom in the north-west extremity of the island of Batavia or Java. It is situated at the foot of a mountain, from which issues three rivers, one of which passes through the town, while the other two inclose it. The town of Bantam, which resembles an immense grove of cocoa nut trees, has no walls or forts, excepting fort Diamond, which contains the royal residence. Each of the streets which compose the town is built with straw and rose wood, and is surrounded with a plantation of cocoa nut trees. The river of Bantam, which is very

shallow, is about 175 feet wide at its mouth; and the bay of the same name affords a commodious and secure anchorage.

Before the inhabitants of the East were visited by the rapacious merchants of Europe, Bantam was one of the most commercial cities in the Indies. The Arabs, the Turks, the Moors, the Chinese, and almost all the Asiatic nations, resorted to this celebrated rendezvous. The Portuguese were the first Europeans that traded with this city; and the English afterwards established a factory in it, and for a long time carried on a lucrative commerce. Another establishment was formed by the Dutch, but they did not succeed so well as the English in gaining the affections of the natives.

The transference of the trade of the Dutch to the neighbouring province of Jacatra, which they had conquered, and where they built the town of Batavia; the removal of the English to Hindostan and China; the ruin of the bay by the coral shoals and the detritus of the mountains; and the destruction of a considerable part of the town by fire; all conspired to reduce the opulence and the commerce of Bantam. The power of its king diminished with the commercial importance of his capital; and in employing the aid of the Dutch against the other kings of Java, he lost his own independence. With the form of royalty he resides as a kind of state prisoner in the Dutch fort, surrounded with female attendants. When he appears in public, he is attended by his Bantam life guards, and likewise by a body of Dutch troops from the garrison. None of the life guards are admitted within the fortress; and neither his subjects nor his children are allowed to approach him without the permission of the Dutch officer.

The king of Bantam maintains a body of native troops, and several armed vessels, for supporting his authority over a territory in the south part of the island of Sumatra. His subjects in Sumatra and Java, sell to the king, at a low price, the pepper which they collect; and this valuable commodity is again delivered to the Dutch at a price somewhat advanced.

Before the trade of this kingdom was monopolised by the Dutch; the Bantamese exported about three million pounds of pepper annually; and in the year 1751, when the kingdom came under the authority of the Dutch, an annual tribute of 100 bhars of pepper, or 37,500 pounds weight, was paid by the king to the Dutch East India Company.

The kingdom of Bantam in Java, is about 400 miles in circumference; but the dominion of the king extends over the province of Succadana in Borneo, the southern part of Sumatra, and all the islands in the streights of Sunda, from Prince's island to Hog's island.

Stravoninus, who, along with some of his fellow travellers, was invited to an entertainment by the king of Bantam, mentions a very singular custom. While the king sat at table, he relieved himself by frequent eructations, and as if it had been a piece of wit, or an exhibition of skill, he was imitated by all the rest of the company. This strange practice, in which his Dutch visitors would not likely be very expert, is considered by his majesty as a pleasing indication of the excellence of his fare, and of the good appetite of his guests.

The kingdom of Bantam is the least populous of any of the kingdoms of Java. It contains only about 5000 families, or about 22,000 inhabitants. From the thick forests and deep morasses, the climate is unhealthy, and the mortality great. East Long. 106°, South Lat. 6°

50'. A full account of the ancient commerce of Bantam will be found in Peuchet's *Dict. de la Geog. Commerc.* and copious details respecting the manners of the people, in Stavoninus's *Voyages*, vol. 1. p. 57; and Staunton's *Embassy to China*, vol. 1. p. 296. (π)

BANTRY BAY, or BEARHAVEN, a large bay in the county of Cork, on the south-west coast of Ireland, about 26 miles long, and from 3 to 5 miles broad. It is reckoned one of the finest bays in the world, and affords a secure anchorage for ships. See CORK. (j)

BANYAN TREE, a celebrated tree which grows in the East, and whose branches strike downwards and take root. By this means the tree, supported by a variety of trunks, often extends over an immense space. An excellent drawing of it may be seen in Hodge's *Travels in India*. (j)

BAOBAB, or BAHOBAB, the name of a huge tree which grows on the west coast of Africa, from the Niger to the kingdom of Benin. The circumference of its trunk is generally, between seventy and eighty feet, though the height of the trunk seldom exceeds twelve feet. The branches, which are remarkably thick, shoot out horizontally to the length of fifty or sixty feet, and their extremities, being bent to the ground by their own weight, they form a hemispherical mass of foliage about 130 feet in diameter. The decayed trunks of the Baobab are hollowed out into burying-places by the negroes, for their poets and musicians. The bodies are thus preserved perfectly dry, and resist putrefaction as if they had been embalmed. A full account of this tree will be found in a paper in the *Mém. Acad. Par.* for 1761, p. 218; *Hist.* p. 77, by Adanson. (π)

BAPTISM, derived from the Greek verb βαπτίζω to dip, or tinge, is the initiatory rite in the Christian religion. Though the words of our Saviour, recorded in Matth. xxiii. 19. are allowed to be the foundation of this ordinance, yet various opinions have been entertained respecting its origin. Whilst some maintain, that it was never practised before the mission of John the Baptist, others affirm, that we ought to look for its origin among the ancient ceremonies of the Jews. Without entering the barren field of controversy, we may be allowed to remark, that as the baptism of Christ differed from that of John, so both differed, perhaps still more, from the washings which were called baptisms by the Jews. It is, however, highly probable, that a ceremony prevailed at the initiation of proselytes into the Jewish church, which bore a striking resemblance to baptism, and which, from its being known to the people to whom his religion was first proposed, might not only suggest the idea to our Saviour, but also induce him to adopt it. If baptism had been altogether unknown to the Jews, they would have contemplated John's conduct with that astonishment which novelty always excites. But they were so far from expressing any surprise, that they spoke of baptism as a familiar rite, and said to him, "Whom baptizest thou then, if thou be neither Christ nor Elias?" John i. 25. Nor is it difficult to trace the source of their ideas of baptism. Not only was Moses commanded to wash Aaron and his sons at their consecration, but no person, who had contracted ceremonial impurity, was admitted into the sanctuary till it was removed by washing. This law must have extended to the Gentiles, who became proselytes of righteousness, and who must have been introduced into the Jewish church by washing as well as circumcision. But though Arian, who calls one of the Jewish proselytes βαπτιστης, baptizet.

and the Mishna, composed about the beginning of the third century, prove that this was then practised; yet the silence of Philo and Josephus, and the Targums, written about the close of the first century, has been adduced to prove, that it was unknown in the time of our Saviour. Had this been the case, however, we can never imagine that the inveterate prejudices of the Jews would allow them to have borrowed that ceremony from his religion. Nor can it be said, that allowing baptism to have prevailed before John, yet as it was not expressly commanded by God, it was unworthy of our Saviour's attention. For, though it is not mentioned by Moses, yet Ezekiel's allusion, xxxvi. 24, 25. gives it almost a divine sanction, and the conduct of Christ in the institution of his supper would correspond to his conduct upon this occasion. As the Jews, without any command from God, concluded their passover by giving to every person a piece of bread and a cup of wine, our Saviour set aside, as the nature of his office required, the rites enjoined by Moses in that ordinance which he had then been commemorating, and retained the bread and cup added by the Jews. In the same manner, when instituting the initiatory rite of his religion, our Saviour set aside circumcision appointed by Moses, and retained the washing or baptism added by the Jews. Impartiality, therefore, leads us to conclude, that though the washing of proselytes in the Jewish church was different in some circumstances from baptism, yet it resembled it so far, as to be a proper foundation on which our Saviour might raise a nobler edifice.

Baptism, in the apostolic age, was performed by immersion. Many writers of respectability maintain, that the Greek verb βαπτίζω, as well as its Hebrew synonyme, sometimes denotes sprinkling; but the various passages to which they appeal, will lead every candid mind to a different conclusion. The circumstances recorded concerning the first administration of baptism are, likewise, incompatible with sprinkling. Had a small quantity of water been sufficient, the inspired historian would never have said, that John baptised in the river Jordan, and in Enon, because there was much water there. The administrators and the subjects of baptism are always described as descending into the water, and again ascending out of it. When Paul affirms that we are buried with Christ in baptism, and raised again, he not only alludes to immersion, but, upon any other supposition, there would be no propriety in the metaphor which he employs. We are likewise said to be saved by *δια λυγξ*, the washing, or, by the bath, of regeneration; where there is a manifest reference to baptism performed by immersion. Immediately after the apostolic age, however, trine immersion was introduced, either to signify the three persons of the Trinity, or the three days that Christ lay in the grave. But as the Arians, who arose in the fourth century, maintained that this implied that the three persons were three distinct substances, it was laid aside, for a short time, by the orthodox.

It is impossible to mark the precise period when sprinkling was introduced. It is probable, however, that it was invented in Africa, in the second century, in favour of clinics. But it was so far from being approved of by the church in general, that the Africans themselves did not account it valid. The first law for sprinkling was obtained in the following manner. Pope Stephen III. being driven from Rome by Astulphus, King of the Lombards, in 753, fled to Pepin, who, a

short time before, had usurped the crown of France. Whilst he remained there, the Monks of Cressy in Brittany consulted him, whether, in a case of necessity, baptism, performed by pouring water on the head of the infant, would be lawful. Stephen replied, that it would. But though the truth of this fact should be allowed, which some Catholics deny, yet pouring or sprinkling was only admitted in cases of necessity. It was not till 1311, that the legislature, in a council held at Ravenna, declared immersion or sprinkling to be indifferent. In this country, however, sprinkling was never practised, in ordinary cases, till after the Reformation; and in England, even in the reign of Edward VI. trine immersion, dipping first the right side, secondly, the left side, and last, the face of the infant, was commonly observed. But during the persecution of Mary, many persons, most of whom were Scotsmen, fled from England to Geneva, and there greedily imbibed the opinions of that church. In 1556, a book was published at that place, containing, "The form of prayers and ministration of the sacraments, approved by the famous and godly learned man, John Calvin," in which the administrator is enjoined to take water in his hand, and lay it upon the child's forehead. These Scottish exiles, who had renounced the authority of the Pope, implicitly acknowledged the authority of Calvin; and, returning to their own country, with Knox at their head, in 1559, established sprinkling in Scotland. From Scotland this practice made its way into England in the reign of Elizabeth; but was not authorised by the established church. In the Assembly of Divines, held at Westminster, in 1643, it was keenly debated, whether immersion or sprinkling should be adopted; 25 voted for sprinkling, and 24 for immersion; and even this small majority was obtained at the earnest request of Dr Lightfoot, who had acquired great influence in that assembly. Sprinkling is therefore the general practice of this country. Many Christians, however, especially the Baptists, reject it. The Greek church universally adhere to immersion.

It has been said, that as the form of words, recorded by Matthew, is never afterwards employed when baptism is mentioned, an adherence to that form is not necessary. But though the express words are never copied, yet we ought not to conclude, that they were not observed. It is probable that, to be baptized into, or in the name of Christ, the words which the inspired writers generally use, were expressions employed for the sake of conciseness. As converts, in the apostolic age, were immediately admitted to baptism, a previous course of instruction was not then judged necessary. But, in the second century, Christians began to be divided into *believers*, or such as were baptised; and into *catechumens*, who were receiving instruction to qualify them for baptism. To answer for these persons, sponsors, or godfathers, were first instituted; and were afterwards, in the fourth century, extended to infants. Then the sign of the cross began to be employed, and was supposed to have singular efficacy in baptism. It is, however, foreign to our purpose to investigate the precise period when the many ceremonies, annexed to baptism, were first introduced. It will be sufficient to observe, that the following rites were all authorised by statutes or practice during the dark ages. At the beginning of Lent, the names of such as desired baptism, and were therefore called *competents*, were given in. During that season, the scrutiny was performed with prayer and

fasting, which consisted of certain questions proposed by the priest, and the proper answers returned by adults, and by sponsors for infants. The principal of these were, "What do you ask? Faith. Do you renounce the devil and all his works? We do. Observe well what you say, that you may never depart from it. We will remember it." The priest, likewise, exorcised them, by laying his hands on their heads, and breathing in their faces, to expel the devil, and inspire them with the Holy Spirit. On one of the days of the scrutiny, the delivery of the creed was thus performed. After mass the bells were rung, and a deacon cried aloud; "If there be any catechumen, pagan, heretic, or Jew here, let him depart." Upon this the catechumens went out. Then the clergy retired to change their habits, and, "Come, ye children, and I will teach you the fear of the Lord," was sung. When this was done, the inferior clergy, having obtained from the priest permission to admit the children, solemnly advanced to the door, and said, "Enter, children, the house of the Lord; listen to your father teaching you wisdom." When the children were come in, the priest said, "Cross yourselves and hear the creed;" and immediately repeated it, sentence by sentence. During the whole scrutiny, the master of the ceremonies carried a branch of hazel and four ivory tablets, like the leaves of a mass book, on which were depicted the actions of our Saviour. These, which were called the pax, were given to the children to kiss while performing their devotions. Those who had undergone the scrutiny were called *elect*, or approved. On Palm-Sunday, the heads of the catechumens were solemnly washed, a ceremony called therefore the *Capitulavium*. When baptism itself was to be performed, they went in solemn procession, with lights and incense, and the choir singing, "Up, Lord, why sleepest thou," to the vestibule of the baptistery; where the priest commanded the catechumens to turn their faces to the west, because Satan dwelt in darkness, to stretch out their hands and say, "Satan, I renounce thee, and all thy works, and all thy pomp, and all thy worship;" then to turn their faces to the east, where light resides, and to repeat the creed, either personally, or by their sponsors. The priest then took a little of his own saliva, and rubbing it on their ears and nostrils, said, *Ephatha*, be thou opened. Then he blessed some salt, and putting a little of it into their mouths, said, "Receive the salt of wisdom." After the benediction of the water, the priest went in and dipped them, one by one, once in the name of the Father, a second time in the name of the Son, and a third time in the name of the Holy Spirit. When they came out, the priest anointed their foreheads in the form of a cross; washed and wiped their feet; kissed them; gave them milk, honey, and wine; put wax tapers into their hands, a chrismal cap upon their heads, and clothed them with a white garment, which being worn on Pentecost gave that day the name of *Whitsunday*. This garment was deposited afterwards in the church, to be an evidence against such as should violate their baptismal engagements. Those who were baptized were called *enlightened*, or instructed.

By baptism, converts make a public profession of their faith in Christ, and in his religion; and are admitted into that family of which he is the head. 1 Cor. xii. 13. As water, likewise, in scripture, is an emblem of the spirit, the water of baptism, clearly, though figuratively, informs them, that they ought, through the spirit, to maintain that purity of heart and rectitude of

conduct, which are congenial to the purity of their religion, and the rectitude of its author. Tit. iii. 5. Rom. vi. 4. But lest we should imagine that this rite works like a charm, we are said to be saved, not by putting away the filth of the flesh, but by the answer of a good conscience; 1 Pet. iii. 21. The influence of baptism, therefore, in sanctifying the heart, must be of a moral nature, and will be easily understood, when we reflect, that every one who dedicates himself to God must be induced, by every motive of duty, of interest, and of honour, to purify himself, even as Christ is pure. But soon after the age of the apostles, many began to imagine that the mere performance of this ceremony procured regeneration and the pardon of sin. Tertullian taught that the holy spirit was always given in baptism; Chrysostom, that the water became unfit for drinking, and drowned the devil; and Augustin, that it washed away original sin. Hence arose the opinion, that baptism was absolutely necessary to salvation, and that all infants who died unbaptized were inevitably damned. This opinion, however, was so repugnant to the feelings of nature, to the dictates of reason, and to the moral attributes of God, that it never universally prevailed. When, therefore, the administration of baptism was impossible, men were allowed to entertain some faint hopes of future happiness. In some cases, likewise, the want of baptism was compensated by the performance of other duties. Such were martyrdom, called the baptism of blood; repentance, called the baptism of fire; and constant communicating, when a person had been admitted to the Lord's supper on a supposition of his having been baptized. But as these substitutes were thought dangerous, recourse was had, in doubtful cases, to hypothetical baptism, in this form: If thou art baptized, I do not re-baptize thee; but if thou art not baptized, I baptize thee in the name, &c. Baptism of the dead was another expedient practised by the African church: to which may be added, baptism for the dead, performed in this manner: When a catechumen died, the priest advanced to the bed, and asked him if he desired baptism: upon this, a man, who had been concealed under the bed, answered, that he would be baptized in his stead; which was accordingly done. But as no expedients could be devised for washing away the original sin of infants, their case was thought almost hopeless. It might have been expected, that the mild and generous declaration of our Saviour, Matth. xviii. 14. would have led them to a very different conclusion; yet Gregory Nazianzen, and Severus, bishop of Antioch, who entertained the most favourable hopes of them, assigned them only a middle state. Pelagius, however, and his numerous followers, by denying original sin, declared them capable of salvation. The church of Rome assert that baptism always confers grace, and justification; but the Armenians and Socinians allow it only to be a sign of grace. The church of England do not positively maintain the necessity of baptism to salvation: though the 27th of their articles seems to imply it. The church of Scotland call it a seal of the covenant of grace, of regeneration, &c. but do not think it absolutely necessary to salvation. Some have thought that it bestows immortality upon the soul: of this number was Dodwell, who also maintained, that only episcopal baptism could bestow this blessing.

The dispute, which has long agitated the church, concerning the proper subjects of baptism, is, unhappily, not yet terminated. Whilst some contend that the

infant children of Christian parents have a right to baptism, others maintain that this right belongs only to those who have been instructed in the religion of Jesus, and profess their belief in his name. But though, at the first propagation of Christianity, all who were admitted to baptism must have been of the latter description, yet when the foundations of the church were laid, the children of believers were, no doubt, admitted before they were capable of personal belief. As Tertullian, about the end of the second century, condemns infant baptism, it has been asserted, that that practice must have then prevailed in the Carthaginian church. But as the children, mentioned by Tertullian, are said to ask baptism for themselves, it is probable that they were not infants in the strict sense of the word. It is an undoubted fact, however, that about 50 years after, in the time of Cyprian, children as soon as born were allowed to be baptized by the council of Carthage. But what is still more to the point, the scriptures inform us, that children were introduced into the church of God by circumcision, from the time of Abraham till the advent of Christ; and as baptism came in the room of circumcision, children ought still to be introduced in the same manner as before. That baptism came in the room of circumcision, will appear from the reasoning of Paul. It is admitted that our Lord's supper was instituted instead of the passover, because that apostle says, That Christ our passover is sacrificed for us, and therefore we ought to keep the feast. But when the same apostle says, That we are circumcised with the circumcision made without hands, buried with Christ in baptism; we have the same reason to conclude that baptism was instituted instead of circumcision. It ought to be remarked, however, that it was instituted, not instead of that circumcision which was appointed at mount Sinai, and which composed part of the law of ceremonies belonging to the covenant of works made there; but instead of that circumcision which was instituted 430 years before, Gal. iii. 17. when God commanded Abraham to leave his country, and which, as Paul expressly declares, belonged to the covenant of redemption. This circumcision, therefore, and the baptism of Christ, were initiatory rites of the same covenant at different periods. But the change in the initiatory rite made no change in the subjects of the covenant. This, then, accounts for the silence of scripture respecting infant baptism. Children were introduced into the church of God in the days of Abraham, at the coming of Christ, and at the present day. When things are to remain unaltered, a command for them to do so, would not only be superfluous, it would be foolish. But when a change is to take place, a command, or, at least, a precedent to authorise it, is absolutely necessary. Since, therefore, neither command nor precedent to this purpose is found in scripture, children ought not to be excluded from that covenant into which they undoubtedly were once admitted.

Before we leave this branch of the subject, we may remark, that as certain employments were thought, in ancient times, not only dishonourable, but unlawful, such persons as professed them were excluded from baptism. Of this description were magicians, image-makers, gladiators, stage players, public drivers, and even strolling beggars. We are sorry to add, that the generous maxim of our Saviour, "Whatsoever ye would that men should do to you, do you even so to them," seems not to have been remembered by his followers, when they

decreed, That the slaves of Christians should not be baptized without the approbation of their masters; but that the slaves of heathens, Jews, and heretics, should not only be baptized without the consent of their masters, but should, by baptism, obtain their freedom.

It has been said, that soon after the apostolic age, many Christian sects rejected baptism. But the accounts of these sects are so obscure and contradictory, that no reliance can be placed upon them. It is probable this error was not so common as has been pretended. Perhaps the Valentinians embraced it. The Paulicians interpreted all that is said of baptism in an allegorical manner, and by the water understood the gospel. The Manichæans, however, did baptize; though the contrary has been generally believed. The Quakers, at the present day, reject baptism, and maintain, that it was appointed only for the Jews on account of their prejudices; or, at most, was to be observed only once, when Christianity was founding, to represent visibly the mystical purification of the soul. In support of this opinion they adduce, 1 Cor. i. 17. But the context clearly proves, that though Paul did not commonly baptize, it was not because it was unnecessary, for the persons to whom he was writing were baptized; but because that office was committed to others, to prevent the bad consequences which might have resulted from its being said that he baptized in his own name. They, likewise, adduce, Ephes. iv. 7, and maintain, that the one baptism, there mentioned, is that of the spirit. But the baptism of the spirit (an expression altogether figurative) was so far from superseding baptism by water, that, according to the express reasoning of Peter, Acts x. 44, it both gave a right to it, and implied the necessity of its being administered. The words of the institution, likewise, as well as the practise of the apostles, are sufficient to prove that baptism was appointed both for Jews and Gentiles. The opinion of some Socinians, likewise, deserves notice. From the manner in which Jewish proselytes were baptized, they maintain, that only converts from a different religion are proper subjects of baptism, and though the children which were born to them before conversion are to be baptized, yet such as are born afterwards are baptized in their parents. But the legitimate office of analogy is not to prove, but to illustrate; and Jewish baptism was so different from the baptism of Christ, that no just conclusion can be drawn from it. The whole tenor of scripture, likewise, even of those parts which were written many years after Christianity was published, always represents believers as personally baptized. Many other arguments might be adduced, but they appear not necessary in this place.

As the commission to baptize was given to the apostles, we conclude that none but the ministers of Christ have authority to baptize. But we are far from thinking, as some have done, that none but the successors of the apostles in office should administer this rite. Indeed, it would not be difficult to prove, that the apostles had really no successors. But if this should not be granted, we would ask, Was Philip, who baptized the Samaritan, an apostle? Was Ananias, who baptized Paul, an apostle? Certainly not. Others, therefore, besides apostles, had authority to baptize. As deaconesses, also, were appointed by the apostles, it is certain that they, at a very early period, administered baptism to their own sex. Immediately after the apostles, bishops only, or such presbyters as were authorised by them, baptized. But in the 2d century, Tertullian informs us, lay-

men baptized in cases of necessity; though in a synod held at Elvira, in 306, this office was restricted to laymen who had not been married a second time. Persons thus baptized, if they survived, were afterwards to be confirmed by the bishop. When Augustin, however, in the 4th century, established the doctrine of original sin, it was supposed that all infants, dying unbaptized, were excluded from heaven. Hence, a licence to baptize was given to midwives; and this was soon extended to any person, whether Jew or Christian, righteous or wicked. The truth of history obliges us to add, that this doctrine was carried so far, that in difficult births water was commanded to be poured upon whatever part of the infant should appear, and when that could not be done, baptism was to be attempted by means of a syringe, in a way that delicacy forbids us to explain. This practice is still authorised in the church of Rome. Even in England, the common prayer books of Edward and Elizabeth permitted lay-baptism in cases of necessity. In the Hampton-court conference, 1603, it was condemned with some difficulty. From that time it has been accounted unlawful.

When Christianity was first established, converts were admitted to baptism without any respect to time or place. But early in the 2d century, except in cases of necessity, the celebration of this rite was confined to the festivals of Easter and Whitsuntide. Baptistories and founts were erected in the 3d and 4th centuries. The novitiate of catechumens, which then universally prevailed, was productive of two bad consequences; some converts, conscious of their imperfections, never imagined that they were sufficiently prepared, and refused to dedicate them-

selves to God; others, of which number was Constantine the Great, unwilling to forsake their sins, and imagining that baptism cancelled every violation of duty, postponed that ordinance to the end of life, that thus they might be dismissed pure to heaven. In this situation things remained till the Reformation. Even after the Reformation, the preface to the book of common prayer, published by authority in 1549, enjoins the administration of this rite, as far as can be done conveniently, only at Easter and Whitsuntide. Neither the reformed, nor the Greek church, observe any particular period; but infants are commonly baptized by the latter on the eighth or tenth day.

Almost all the ceremonies formerly mentioned are still retained in the church of Rome. The Greek church observes nearly the same form, but employs immersion. Immersion, either single or trine, is adopted in all the Oriental churches. The reformed churches, in general, reject human inventions, but observe sprinkling. The Baptists suppose immersion and a personal profession of Christianity absolutely necessary to the validity of the deed. Baptism has sometimes been performed in wine, when water could not be obtained. In ancient times, the baptism of such as had committed public sins was often, by way of punishment, deferred till the end of life. The ancient rubrics almost universally condemn private baptism, except in cases of necessity, but grant a dispensation to the children of kings and princes. The giving a name to the child at baptism, though probably derived from the conduct of the Jews at circumcision, is by no means to be considered as part of the rite. (x)*

* The allusion to the Quakers, as rejecting baptism, in the foregoing article, is not correct, as will appear by the following extract from the work of an author, who, with several others, have clearly demonstrated the belief of that people in the baptism of Christ; and for more full information and satisfaction on this subject, the reader is referred to a serious perusal of the treatise thereon. (J. EVANS.)

“The self-flattering notion that the new birth of the Spirit is either concurrent with, or consequent upon, the ministration of water-baptism is neither supported by scripture nor experience. If it insensibly accompany it, how do we know it? If it immediately follow, how do its fruits appear more in those who have received water baptism, than in those who have not? “The fruit of the spirit,” saith the apostle, “is love, joy, peace, long-suffering, gentleness, goodness, faith, meekness, temperance.” (Gal. v. 22, 23.) “The fruit of the spirit is in all goodness, and righteousness, and truth.” (Eph. v. 9.) Are these fruits more conspicuous in the baptized, than in the unbaptized. If those who are baptized with water are born of the spirit, and made heirs of the kingdom of heaven, how comes it that such as have received it, either in adult age or infancy, and become afterwards awakened to a sense of their condition, are still conscious of a body of sin remaining within them, and are made to cry out in anxiety of soul, A saviour, or I die! a redeemer, or I perish for ever! Are not such painfully sensible, that they still want remission and regeneration, notwithstanding their water baptism?

If any say, This may arise from sins committed after their baptism; I answer, the apostle John saith, “Who-soever is born of God, (and abideth in him) doth not commit sin; for his seed remaineth in him, and he cannot sin, because he is born of God.” (1 John iii. 9.) But it is evident, in fact, that he who is baptized only with water can sin as freely and fully as he who is not; therefore he who is baptized with water is not in consequence born of God.

True Christian baptism is not that which puts away the filth of the flesh, but that which produceth the answer of a good conscience towards God. Thus, it is not the figurative, but the effective baptism, pointed to by the figure, the refining baptism of the Holy Ghost, that saveth.

It is well known by the experience of many, that this baptism is gradually effected by spiritual immersions of the soul, according to the measure of corruption it hath imbibed, and to the strictness or laxity of its attention to the great Baptizer. A sense of its sinful condition, with the distance it stands at from the God of perfect purity, is first given it, whereby it is brought into self-abasement, contrition, and, at length, into humble resignation of all to him. Thus it becomes baptized into the similitude of the death of Christ, which is a death unto all that is of a carnal and sensual nature. Through baptism it also riseth with him into newness of life, which enableth it to bring forth the fruits of the spirit to his praise. To those who had thus followed Christ in the regeneration, the apostle said, (Col. ii. 10. &c.) “Ye are complete in him, who is the head of all prin-

cipality and power. In whom also ye are circumcised with the circumcision made without hands, in putting off the body of the sins of the flesh, by the circumcision of Christ; buried with him in baptism, wherein also ye are risen with him, through the faith of the operation of God."

True Christian baptism is a great and important work; the work of Christ himself, whereby the soul is measurably baptized into his spirit, and endowed with its virtues. This is quite another thing than a ceremonious formalization under his name. The latter is easy to the flesh, but the former crucifies it. (Gal. v. 24.) "They that are Christ's, have crucified the flesh with the affections and lusts."—(Gal. iii. 27.) "As many of you," said Paul, "as have been baptized into Christ, have put on Christ." To take the name christian upon us, and to be joined to the promiscuous body of a professing church, is only to put on a profession of Christ; but to have really put him on, is to be endued in degree with his Holy Spirit and nature; which those, who have been baptized into him, certainly are. For, (2 Cor. v. 17, 18.) "if any man be in Christ, he is a new creature; old things are passed away, behold all things are become new, and all things are of God." Such are become inwardly united to Christ, grafted as branches in him the living vine, daily partaking of his life and virtue, which renders them fruitful according to their measure; to these he pressingly shews the necessity of care and watchfulness, that they may abide in him: (John xv. 4, 5, 6.) "As the branch," said he, "cannot bear fruit of itself, (or) except it abide in the vine; no more can ye, except ye abide in me. I am the vine, ye are the branches. He that abideth in me, and I in him, the same bringeth forth much fruit; for without me ye can do nothing. If a man abide not in me, he is cast forth as a branch, and is withered." This manifests that maxim, once in grace, and always in grace, to be no letter than a broken reed, and dangerous for any who have been sensible of a divine visitation to rest their salvation upon.

It is improper to imagine, that the sign of circumcision given to Abraham and his descendants was a type of water-baptism, which was only an outward and typical sign itself. Ceremony and substance are type and antitype; not ceremony and ceremony. What the circumcision of the foreskin pointed to, was the inward circumcision of the fleshly heart, called for by Moses, Deut. x. 16, and promised, chap. xxx. 6. Water-baptism in like manner typified (Tit. iii. 5.) the washing of regeneration; which is effected by the renewing of the Holy Ghost.

Mark xvi. 16. "He that believeth and is baptized shall be saved." This must be understood of that saving faith which worketh by love, to the purification of the heart, and of that saving baptism which operates to the answer of a good conscience. If we do not believe unto obedience, if we have not that faith which overcomes the world in our hearts, we shall not be found in the faith once delivered to the saints; and if we are not (John xiii. 8.) washed by the Lord himself, whoever else may baptize us, we have no part in him. Simon Magus believed and was baptized with water, yet remained so far from a state of salvation, that when he offered money for the Holy Ghost, the inspired apostle sharply answered him, (Acts viii. 13, 21, 23.) "Thou hast neither part nor lot in this matter, for thy heart is not right in the sight of God—I perceive that thou art

in the gall of bitterness, and in the bond of iniquity." What therefore had this bare believing and water-baptism done for him?

Misapprehension at first, and tradition afterwards, having inculcated water-baptism as a permanent institution of our Lord's, and an indispensable part of the gospel ministration, some of its advocates have weakly argued for it as such, from his washing (John xiii.) the feet of his disciples, and directing it as their duty to do the like to each other. But this instance had no relation to that ceremony, for our Lord was not then instructing his followers how to initiate new converts, but figuratively showing them what their own conduct should be amongst themselves, by setting them a pattern of humility, condescension, and brotherly kindness one to another. This undoubtedly was his intent; not the establishment of the exterior act of pedal ablution.

Water-baptism being an essential part of John's commission, he properly admitted his disciples by it; which the great Administrator of spiritual baptism did not. When he called to any, Follow me, those who obeyed his call immediately became his disciples, without any ceremonial. We find he accepted Peter, Andrew, John, James, Levi, Philip, Nathaniel, and Zaccheus, without either baptizing them, or directing them to be baptized with water. As it was then, so it remains to be; those who are obedient to his call are his followers, whether they are water-baptized or not. On the contrary, those who obey not the internal manifestations of his spirit, are none of his, whoever baptizeth them with water. Formality may render any man a nominal Christian; but the effectual baptism of the spirit only can make a real one.

The practice of sprinkling infants, under the name of baptism, hath neither precept nor precedent in the New Testament. For want of real instances, mere suppositions are offered in support of it. Because it is said in the case of Lydia, (Acts xvi. 15.) that she was baptized, and her household; and by the apostle, "I baptized also the household of Stephanas;" it is supposed, there might be infants, or little children, in those households; from whence it is inferred such were baptized. But could such improbabilities be ever so well ascertained, they would fall very short of proving the practice a divine and perpetual institution.

The words of our Saviour, (Mark x. 14.) "Suffer the little children to come unto me," afford no ground for infant baptism. He made no mention of it, much less did he recommend it as requisite to prepare them for his kingdom; for he declared their fitness already: "Forbid them not," said he, "for of such is the kingdom of God." Who are they that presume to forbid such, as unqualified, to enter it, unless they are sprinkled by their hands? The intention of our Lord in admitting the children to him appears to have been, that he might exhibit them as examples of innocence and fitness to those actual sinners about him, to whom he said, "Verily, I say unto you, whosoever shall not receive the kingdom of God as a little child, he shall not enter therein." Had he meant to adopt and establish pædo-baptism as a standing ordinance, a fairer opportunity could hardly offer, either to baptize the children himself, or command his disciples to do it; neither of which he did; but graciously shewed his acceptance of them without it, for "he took them up in his arms, put his hands upon them, and blessed them."

We never find either the Lord Jesus, or his apostles,

preaching up water-baptism as his, nor telling the people they cannot be his followers without it. His conditions of discipleship are not so easy to the carnal mind. (Luke ix. 23.) "If any man will come after me," said he, "let him deny himself, and take up his cross daily, and follow me."—(Ibid. xiv. 27.) "Whosoever doth not bear his cross and come after me, cannot be my disciple." Hence it is clear, that it is not water-baptism, nor any kind of rituals whatsoever, which renders any man a Christian in our Saviour's account; but obedience to the operation of his Holy Spirit, which humbleth the heart, purifieth the soul, and baptizeth it measurably into the divine nature. But mortification of self being irksome, and highly disagreeable to the flesh, too many are rather willing to content themselves with assuming the name Christian under the outward sign, than to endure the pain of crossing their carnal propensities, in order to put on Christ, and become Christians indeed. But let such attentively consider this salutary admonition of the apostle. (Gal. vi. 7, 8.) "Be not deceived; God is not mocked; for whatsoever a man soweth, that shall he also reap. For he that soweth to his flesh, shall of the flesh reap corruption; but he that soweth to the spirit, shall of the spirit reap life everlasting."

The command, "Go teach all nations, baptizing," &c. shews that the baptism therein meant should be as general as the preaching there intended, both among Jews and Gentiles; which water-baptism evidently was not. For Paul, who was sent chiefly to the Gentiles, was very sparing in the use of it, and thanked God that he had baptized but two or three families with it, declaring that was not his commission; yet he planted many churches, which contained numbers who received the spirit, and walked in the faith and fellowship of the gospel, and who were as real Christians without water-baptism, as others were with it. This shews, that it was neither made an essential, nor an integral part of Christianity; and, consequently, that the continuance of it was but an occasional condescension; for it having been an ancient custom, both among Jews and Gentiles, to initiate their proselytes by it, and also administered by John under divine authority, and taken up from him by the disciples of our Lord, it was become a ceremony of considerable account with the generality, who saw not sufficiently into the purity and simplicity of the Gospel: therefore it could not, even after the baptism of Christ by the Holy Ghost appeared, be every where laid aside suddenly; neither was it required so to be, but, as John intimated, to decrease, or fall into disuse by degrees. In like manner, the apostles also occasionally complied with the rites of the Mosaic law in various particulars; as circumcision, vows, shavings, exterior purifications, sacrifices, anointings, &c. all which were permitted for a season; yet, had the professors of Christianity abode in the spirit of it, and sincerely sought a growth therein, ceremonials of all kinds would soon have been extinct in the church. But, instead of growing in grace, and in the saving knowledge of our Lord Jesus Christ, a falling away began early to take place, and in proportion as the life of religion dwindled, forms and shadows were more and more fastened upon, and gradually increased upon the declining state of the church, as the spirit of antichrist gained ground.

We read, Eph. v. 25, 26, "Christ also loved the church, and gave himself for it, that he might sanctify

and cleanse it with the washing of water by the word; that he might present it to himself a glorious church, not having spot or wrinkle, or any such thing; but that it should be holy and without blemish." This is the work of Christ himself, and therefore is done by his own spiritual baptism. The water of the word signifies its cleansing power, as (1 Pet. ii. 2) the milk of the word denotes its nutrimental virtue; and this sanctifying word is the issuing forth of the spirit of Christ for great and gracious purposes, who is himself the emphatical and all powerful Word, through whom the Father effects his will, and communicates all things to his people. By him alone the church can be rendered holy, and presented without blemish.

According to apostolic doctrine, there is but one baptism now remaining in force: (Eph. iv. 5.) "One Lord, one faith, one baptism." And as the Christian dispensation is that of Christ, the one baptism must be the baptism of Christ; which is not by water, but by the Holy Ghost: (1 Cor. xii. 13.) "For," saith Paul, "by one spirit are we all baptized into one body." By receiving the same spirit, we become of the same spiritual body. The outward and visible sign may introduce us into membership with such an outward and visible church as holds with the retention of the sign; but it is the effectual operation of the spirit of Christ in us that renders us members of his body, or true spiritual church.

The distinction betwixt our Saviour's baptism, and that of John, lies not in the same elementary ministration after a different mode, or under another form of words. (Mark i. 8.) "I," saith John, "indeed have baptized you with water; but he shall baptize you with the Holy Ghost." This plainly shews, that the baptism of Christ and that of John were two separate baptisms, and that they are perfectly distinct, and different from each other as type and antitype.

Some have argued, that as the soul is not properly a man without the body, nor the body without the soul, but both in conjunction make the man; so water-baptism and spirit-baptism are both requisite to make up the one Christian baptism. But though soul and body be the two constituent parts of a man, the two baptisms have no such constitutional connexion. That of the spirit, being the effective reality, is complete in itself; but that of water was only a temporary figure, and no more a part of the baptism of Christ, than the circumcision of the foreskin was a part of the circumcision of the heart.

The transaction of Philip with the Ethiopian eunuch, (Acts viii.) hath been treated as if meant to give a miraculous sanction to water-baptism. But it is evident, this great and well-disposed man had been at Jerusalem with a pious intention to worship the true God, who, knowing the sincerity of his heart, sent Philip to instruct him, and to preach his son Jesus to him, as the Saviour of mankind. After he had so done, as they passed near a certain water, the eunuch, judging, according to the custom of both Jews and Gentiles, that he must be entered as a proselyte by the usual ceremony, made a motion to Philip that he might be there baptized. And, as the apostles, in this early time of the gospel, saw fit occasionally to condescend to this and various other rituals, Philip went into the water with him, and baptized him. But, if any miracle was wrought, the text affords no testimony that it was done to give a sanction to water-baptism, nor that it is an institution of our

Lord. It doth not appear in the New-Testament, that he ever instituted, adopted, or once administered water-baptism himself. The evangelist declares, that (John iv. 2.) "Jesus himself baptized not:" that is, not with water; and undoubtedly for this reason, because it was not his baptism, but John's, who was the only person we find divinely commissioned for it. Our Lord's submitting himself to it, under John's ministration, was upon the same foot that he submitted to the Jewish ceremonials. They had all been divinely commanded, and, in acknowledgment of them as such, he countenanced the practice of them, till the period of their obligation should arrive, by the establishment of his own spiritual dispensation.

No one outwardly-connected body upon earth hath a right to engross to itself the title of the true church, and thence to assert, there is no salvation but within its own peculiar pale; for all professing churches are composed, more or less, of a promiscuous number of those who love and fear God, and of those who regard him not with that reverence and subjection all ought to do. Those who walk most in the spirit will undoubtedly be most in his favour; but without obedience thereunto, none can be so; (Rom. viii. 14.) "For as many as are led by the spirit of God, they are the sons of God;" and, (Rom. 9.) "If any man have not the spirit of Christ (as his leader) he is none of his." Whatever doctrines he may profess, and whatever forms he may practise, he is no true follower of Christ. (John x. 27, 28.) The sheep of Christ hear his voice; they carefully regard the leadings of his spirit, wherein he gives unto them eternal life, and none shall pluck them out of his hand. Here is the pale of true salvation; for (John 16.) there is but one fold under one shepherd. Of this fold are the righteous under all denominations; for (Acts x. 34, 35.) "God is no respecter of persons; but in every nation, he that feareth him, and worketh righteousness, is accepted with him."

Our Lord declared himself to be the door of entrance into this fold. (John x. 7, 9.) "Verily, verily, I am the door of the sheep—I am the door, by me if any man enter in, he shall be saved." No ceremonial can open this door, much less can it be the door. By the com-

munication of faith to the returning sinner, Christ opens the way for him to be purified in heart, and fitted for admission into his church militant here, and the church triumphant hereafter: (Eph. ii. 8.) "For by grace are ye saved, through faith, and that not of yourselves; it is the gift of God."

He is also the means of grace: (John i. 17.) "For the law was given by Moses; but grace and truth came by Jesus Christ." And it always comes by him; for, saith his apostle, (Eph. iv. 7.) "Unto every one of us is given grace, according to the measure of the gift of Christ."

The seal or pledge of the kingdom of heaven is what entitles to, or insures it. This is the oil of divine grace, kept burning and shining in the lamp of the wise virgin-soul, or, in other words, the earnest of the spirit in the renewed heart. (2 Cor. i. 21, 22.) "He who establisheth us with you in Christ," saith Paul, "is God, who hath also sealed us, and given the earnest of the spirit in our hearts." (Eph. i. 13.) "In whom also, after that ye believed, ye were sealed with that holy spirit of promise"—(Eph. iv. 30.) "Grieve not the holy spirit of God, whereby ye are sealed unto the day of redemption." The Christian seal, therefore, is the sacred impress of the holy spirit.

The mark or badge of true Christian fellowship is love: (John xiii. 35.) "By this shall all men know that ye are my disciples, if ye have love one to another." This is not to be understood of a bare natural affection, or the attachment of party; but of that uniting love which is shed abroad in the hearts of the regenerate by the Holy Ghost; to which the apostle John thus exhorts, (1 John iv. 7.) "Let us love one another; for love is of God, and every one that loveth is born of God, and knoweth God."

Typical forms may be made as doors of entrance into outward and visible churches, and as marks and pledges of fellowship amongst men; but they are not such to the spiritual community of the invisible church of Christ, the members whereof, (1 Pet. ii. 5.) "as lively stones, are built up a spiritual house, an holy priesthood, to offer up spiritual sacrifices, acceptable to God by Jesus Christ. JOSEPH PHIPPS.

BAPTISTA PORTA. See the *History of OPTICS*.
BAPTISTERY, in its proper acceptation, is a place where water is kept for the administration of baptism. We are certain from Scripture, that when Christianity was first established, no particular place or edifice was appropriated to this ceremony. The river, the lake, or the pond, which was most convenient, was always chosen, and history is not without many instances of the performance of baptism in private houses. As this was the common practice in the time of Justin Martyr and Tertullian, we are sure baptisteries were not erected before the end of the second century. It is probable that, about the middle of the third century, edifices of this kind began to be founded in such towns and cities as were at a distance from fountains or streams. Yet it must not be denied, that where a fountain or stream could be obtained, the baptistery was erected over it; and where it could not, water was conveyed to the place by pipes, and in the same manner was discharged when found necessary. Hence the church to which the baptistery belonged was generally dedicated to John the

Baptist, and received the name of *St John in fonte*, or *ad fontes*, that is, the church near the fountain, or baptistery. Though the origin of baptisteries is unknown, yet we may hazard a conjecture that they were first erected in imitation of the Pool of Bethesda, and its porches or cloisters, famous in the history of our Saviour, to which they appear to have had some resemblance. But as the church was then exposed to poverty and persecution, and its members were generally in the lowest walks of life, baptisteries must have been mean and simple, like the persons who employed them. When Christianity, however, was established in the Roman empire by Constantine the Great, the church aspired to opulence and grandeur; and as external rites have too often superseded internal piety, and outward splendour compensated for moral virtue, the professors of Christianity, who were then the first men of the state, imagined that they would procure the pardon of sin, and conciliate the friendship of Heaven, by expending their superfluous wealth in building magnificent structures for religious worship. But though bap-

tisteries could then boast of considerable elegance and splendour, yet they were, for many years, raised at a distance from the churches. The page of history informs us, that the first baptistery which was built adjoining to any church, was annexed to the cathedral of Rheims, for the baptism of Clovis king of France, who was converted by his queen Clotilda, and baptized by Remigius, bishop of that place, in 496. Though there were many churches in one city, yet for the most part there was but one baptistery, which was generally annexed to the principal church. It is a curious fact, in the history of superstitious usurpation, that the church to which the baptistery belonged, claimed, from that circumstance, a superiority over the rest, and employed it as a foundation on which to rear the antichristian fabric of spiritual dominion. In succeeding ages, the bishop of the baptismal church granted, in the plenitude of his power, licences to other churches to erect baptisteries; but still reserved to himself that superiority over them which he had formerly usurped. But as the ceremonies with which baptism was then celebrated, were attended with some little expense, a provision for that purpose became necessary. Hence baptisteries became, not only engines of power, but sources of wealth. This was more particularly the case after donations for religious purposes began to be considered as expiatory for sin. Then the hopes and the fears of superstitious minds prompted them at first to endow baptisteries with milk, honey, wine, oils, and salts. To these followed cups, vases, &c. which, being marked with the initial letters of John the Baptist's name, gave rise, perhaps, to baptismal inscriptions. Habits for the priests, and money for the support of the poor, and of those persons who were employed in instructing catechumens, and officiating at the baptistery, were added. Pictures, and other ornaments for embellishing the edifices, were also given: but though these, in general, had some reference to John the Baptist, or to the ceremony of baptism itself, yet their evident tendency was to foster pride, to strengthen superstition, to subvert the foundation of virtue, and deaden the spirit of religion.

From a survey of the famous edifices of this kind which still remain, we find that a baptistery was an octagonal structure, with an arched roof like a dome. In the Lateran baptistery at Rome, which is the most ancient in that city, the cupola is supported by eight pillars, and between them and the wall there is a piazza or broad walk quite round. The porch or vestibule of the baptistery was sometimes also supported by two pillars; and in this the confession, exorcism, and unction of the catechumens took place. To the outside of the walls of some baptisteries small buildings were added, in the form of cloisters; and the whole circumference, in the inner sides of the walls, was divided into a number of apartments, which were employed as vestries, oratories, and school-rooms. The middle of the building was a large hall, where the priests, the catechumens, and the spectators assembled, when baptism was to be administered; and in the centre of this hall was an octagonal bath, which, properly speaking, was the baptistery, and into which the persons to be baptized descended by steps. As the catechumens were often naked when baptized, decency required that the men and the women should be separated. For this purpose many baptisteries had more than one bath, and sometimes water was conveyed into the side-rooms.

The inside of the pool was frequently ornamented with the most beautiful Mosaic work. This is particularly the case with the celebrated baptistery at Ravenna. In the centre is an emblematic representation of the baptism of our Saviour, and on the sides are the twelve apostles in long habits, with their names, and many other figures, all of the most exquisite workmanship. Baptisteries were taken into churches in the sixth century, and continued to be used in the time of Charlemagne.

Some time after baptisteries were built, fountains were erected in them for the baptism of infants. These were small baths raised on platforms, to which the administrators ascended by steps, and in which they could immerse children without going into the water themselves. When immersion was superseded by sprinkling, a basin of water was placed in the font, and from it the ceremony was performed. Many fonts still remain both in England and on the continent, and are beautifully ornamented with various figures relative to the baptism of our Saviour, and to the ceremonies which were annexed to baptism in the dark ages. Some of these fonts were moveable: amongst which may be mentioned the silver one which was kept at Canterbury, and which was generally brought from thence to the place where any child of the royal family was to be baptized. It was hung round on the outside with cloth of gold, and lined on the inside with cloth of linen, puckered and folded, to prevent the child being bruised. The whole was covered with a canopy of rich damask, bordered with fringe or cloth of gold, and above the basin, or font, was a gold or silver dove, to represent the Holy Spirit. See Jastini Mart. *Apol.* 2. Tertuliani *de Baptismo*. Joan. Ciampini *Vet. Monumenta*, cap. xxv. Du Cangii, *Glossar. in verb.* Baptistarium. Paciandius. Muratori, *Antiq. Ital.* Bingham's *Antiq.* book viii. Robinson's *History of Baptism*. (N.)

BAPTISTS, are a sect of Christians who derived their name from the peculiar opinions which they held respecting baptism, and began, about the time of the Reformation, to claim the attention of the ecclesiastical historian. When we take a superficial view of this sect, collected as it were into one society, and in its present embodied form, nothing appears more easy than to write its history, and to specify the doctrines which are peculiar to it. But when we come to examine it more minutely, and endeavour to analyse it into its elementary parts, we find that it is composed of very different materials, that its origin is hid in the darkness of antiquity, and that its history, for many centuries, is only the history of individual persons. If opposition to the mode in which baptism is commonly administered be the distinguishing characteristic of this sect, Tertulian, who lived about the end of the second century, may be accounted one of its earliest founders. A short time afterwards, Agrippinus, a Carthaginian bishop, and many of the neighbouring clergy, rejected the baptism which were then administered, and re-baptized all those who joined this society. Cyprian and his followers adopted the same sentiments in the third century. From Carthage these opinions migrated to the East, and Firmilian, bishop of Cæsaria, and many other bishops in Asia, re-baptized. The Novatians and Donatists likewise condemned baptism as then commonly administered, and embraced the sentiments of those who re-baptized. The ostensible reason which all these persons assigned for this conduct was, the wickedness of

those who were universally admitted to baptism, and which, in their opinion, rendered the ordinance altogether invalid.

But soon a different cause impelled the professors of Christianity to the same line of conduct. In the council of Nice, held in the year 325, it was decreed, that as the Paulianists denied the doctrine of the Trinity, and consequently omitted the names of the Son and of the Spirit in the administration of baptism, their baptism was nugatory; and hence all that joined the orthodox from that sect were re-baptized. The Arians, on the other hand, rejected the baptism of the orthodox, because it implied an acknowledgment of the divinity of the Son, and of the personality of the Spirit, and therefore they re-baptized all those who came over to them from the orthodox. It is a very curious fact, therefore, that at that time the whole church, though for very different reasons, might be accounted baptists, and esteemed re-baptization necessary for preserving the purity of the church.

But in the twelfth century several denominations of Christians arose, who, from the peculiar tenets which they adopted, pursued the same line of conduct respecting baptism. The Waldenses and Albigenses at that period, as well as the Wickliffites in the fourteenth century, inveighed bitterly against the immorality of the clergy, accounted baptism invalid when performed by a priest whose conduct was unworthy of the Christian character, and re-baptized all those to whom that ceremony had been administered by men who were openly profane. Socinus and his followers, who lived about the time of the Reformation, as well as the baptist churches in Holland and Germany at the present day, imagine that a personal profession of Christianity is essential to baptism, and hence they re-baptize all those who were baptized in infancy. The Greek church maintains that immersion is absolutely necessary to the validity of the deed, and for this reason they re-baptize all those to whom baptism had been administered by sprinkling. The baptists of Britain, Poland, Lithuania, Transylvania, and America, all agree, that immersion, and a personal profession of faith and repentance, constitute the very essence of baptism; hence they re-baptize all who have been baptized in infancy in any manner, or by sprinkling, when they have arrived at manhood.

But though there were many individuals, and even some small societies, who maintained the opinions, and deserved the appellation of baptists, before the Reformation, yet it was only about that period that the insulated members were collected into one body, were properly organized, and attracted the attention of Europe. As many of the nations, who had groaned for ages under the superstition and tyranny of the see of Rome, began then to break their fetters, to assert their independence, and to rise to the dignity of men and Christians, the baptists imagined that the glorious period was come, when their opinions would universally prevail, and the personal reign of Christ would commence upon the earth. Giddy and intoxicated with liberty, for which they had long sighed in secret, but to which they had never before been accustomed, and animated and directed by passion and imagination rather than by reason and the word of God, they surrendered their understandings to all the wildness of enthusiasm, and hurried into those scenes of indecency, of rapine, and of bloodshed, which in the year 1533 alarmed the

states of Germany, desolated the city of Munster, and disgraced the character of the whole party. (See ANA-BAPTISTS.) But though the odium of absurdity and wickedness has been indiscriminately thrown upon the whole party, yet it is as ungenerous as unjust, to affirm that all the baptists approved, far less followed, the standard of Matthias or Boccold. No sooner, therefore, had the arm of power inflicted upon the leaders of the insurgents that punishment which their crimes merited, and struck with terror such as might have been tempted to imitate their example, than the sect appeared to return to reason and to common sense. This happy change was principally effected by Menno Simon, a man, who, from being a popish priest of the most infamous character, became a baptist teacher, equally distinguished for the mildness and humanity of his disposition, as for the purity and rectitude of his conduct. By his prudent counsels and unwearied diligence were their societies reduced to form, their discipline established, their doctrines defined, and a spirit of union and of moderation infused into the whole mass. The obligations which they owed to their amiable and disinterested leader inspired them with the warmest gratitude, and the deference which they paid to him bestowed upon them the appellation of Mennonites, which they still bear. Their situation, however, was still far from being agreeable. Unacknowledged by any of the powers of Europe, and dreaded from the remembrance of their late fanaticism, they owed their security to the generosity of the rulers, and not to the protection of the laws; and the imprudence of a few of their own members, as well as the interest, the caprice, or the bigotry of the magistrate, might at once have overwhelmed them with all the evils of persecution. It was to William prince of Orange, a name illustrious in the annals of civil and religious liberty, that they were indebted for the first legal toleration which they enjoyed. His son Maurice imitated his generous and enlightened example; but the influence of their protection was not only confined within the boundaries of their dominions, but was even defeated within that narrow circle, by the opposition of many to whom the subordinate offices of their government was committed. We may add, that in England, in 1538, some of this sect were burnt in Smithfield, and even in the seventeenth century they were not exempted from the storm of persecution which was raised against the reformed churches. They are, however, now protected in Britain, by the act of toleration, 1689; and they enjoy equal security in many other nations of Europe.

It must have already occurred to our readers, that the baptists are the same sect of Christians which we formerly described under the appellation of ANA-BAPTISTS. It is but justice to acknowledge, that they reject the latter appellation with disdain; and maintain, that as none of the forms adopted by other churches are consonant to scripture, the baptism of these churches is in reality no baptism. Hence, in their opinion, they do not re-baptize. Indeed, this seems to have been their great leading principle from the time of Tertullian to the present day. According to them, something essential to baptism, either in the subjects, or in the administrators, or in the mode, was omitted, which rendered the rite altogether nugatory; and hence they asserted, that their baptism was the first that was administered to such as were proper subjects of it.

Though the Calvinistic and Arminian baptists are by

far the most numerous at the present day, yet there are many baptists who adhere to the dogmata of Arius, Pelagius, and Socinus. Hence it is, that this sect may be said to be divided into a number of lesser sects, each distinguished by its own name, and by its particular opinions. To specify all these would be inconsistent with our plan. We may, however, be allowed to remark, that the following opinions, though not adopted by the whole body of baptists, have yet pretty generally prevailed. 1. That our Saviour's body was not derived from the substance of his mother, but was created in her womb by the Holy Spirit. 2. That during the Millenium, Christ will personally reign over his church on earth. 3. That private Christians have authority to preach the gospel. 4. That the gospel supersedes all those civil institutions which men have established for the support and regulation of society. 5. That true Christians ought not to exercise the offices of magistracy. 6. That war, even in self-defence, is unlawful. 7. That no Christian should confirm his testimony by an oath. 8. That the Sabbath was not changed from the seventh to the first day of the week. 9. That a community of goods was established by the gospel. And 10. That Christians, in imitation of their Lord, ought to wash the feet of their guests. But the opinions which are acknowledged by all the baptists, and which may be accounted characteristic of the sect, are, 1. That the church of Christ upon earth is an assembly of real saints, and must be kept pure from the wicked. 2. That no man is born a member of any particular church, but must voluntarily choose for himself. 3. That baptism ought only to be administered to adults, upon a public profession of faith and repentance, by immersion. 4. That civil rulers have no authority to enact laws, or to enforce obedience in matters of religion. 5. That the ministers of religion have no power over the opinions or consciences of their hearers, but are to be accounted mere teachers. And, 6. That the religious establishment and form of worship, in Christian churches, ought to be congregational or independent. See Tertulliani *de Baptismo*. Cypriani *Epistole*. BAR SUR ORNAIN, formerly BAR LE DUC, is the chief town of the department of the Meuse, in France. The articles of the commerce of this town are, hemp, wood, and wine. The hemp is very abundant, and is employed in the fabrication of coarse linens. The wood consists of planks of oak, and deal boards. The Marne, into which the river Ornaïn discharges itself, facilitates the intercourse between this town and Paris. Bar sur Ornaïn is celebrated for its confectionaries of fruit, and its wines are reckoned equal to those of Champagne. All kinds of steel goods are manufactured in the suburbs. Population 6961. East Long. 5° 11', North Lat. 48° 46' 5". (O)

BARABA, a steppe or extensive plain on the western verge of Siberia, situated between the rivers Irtysh and Oby. This steppe exceeds 600 versts in length from north to south, and 400 in breadth from east to west. The whole of this extensive region is a continued flat, diversified only by forests of birch-wood, and by lakes, both of salt water, and of fresh. The soil and the cli-

mate are extremely favourable to agriculture. Some of the lands indeed are very low and marshy, but in general they are either covered with fine herbage, or with luxuriant crops of grain. The southern part of this plain, towards the Irtysh and the mountains of Altay, is by far the driest, but it is likewise the most barren, and the least adorned with wood. Deep forests spread over the north, and overshadow the lower banks of the Oby. From the general appearance of the steppe of Baraba, naturalists have concluded that it must once have been completely covered with water, and afterwards have contained a much greater number of morasses and lakes than at present. The present inhabitants, indeed, affirm, that even within the memory of some of their old men, the acquisitions made by the firm land, in consequence of the diminution of the lakes, and the drying up of pools, reedplots, and marshes, has been very observable. No country in Siberia abounds more in water game of every description than the plain of Baraba. Its lakes swarm with pike, perch, and other species of fish; and their surface is covered with fowls, whose beautiful plumage yields a very lucrative branch of commerce.

The people who occupy this steppe are called by the Russians BARABINZES, or BARABINZIANS; and, from the diversity of their features, appear to be descended from several different tribes. They had been successively conquered by the Kirghises and Soongares; and when Siberia was subdued by the Russians, their numbers were very small, and they were so stupified by oppression, that they could relate no particulars whatever of their history. The greater part of them appear from their phisognomy to be of Tartar origin; the long, half-opened eyes of others of them evidently indicate their descent from the Mongoles, while the Kalmauc countenances of a third part of them bespeak their affinity with the Soongares, their former conquerors. The vapours constantly exhaled from their lakes and marshes render their atmosphere so gross, as even to affect the complexions of these people, who are in general very sallow; while the same cause imparts to their minds more than Dutch indifference, and more than Bœotian dulness. Agitated by no strong passions, they are almost free from vice, and never guilty of any flagrant crime. Disgraced neither by intemperance, dishonesty, nor violence, they might be regarded as one of the most amiable nations on earth, did not their torpid apathy remind us, that they are not vicious only because they have no temptation, and were they not degraded by their stupidity almost to the level of brutes. Till the conquest of their country by the Russians, they derived scarcely any advantage from the fertility of their lands. Scanty herds of cattle and of horses constituted all their wealth; and fish and wild fowl were their principal food. There are now several colonies of Russians established among them, who rear rich crops of grain, have established some lucrative branches of trade, and may in time improve not only the appearance and resources of the country, but also the manners and mental character of the simple, but rude, natives. Every village in the Baraba is under the direction of a chief, and every district is governed by a sort of prince, called a yaouta. The only advantage connected with this elevation is the respect and seeming obedience which it commands. The Barabinzians were conquered by the Russians in the year 1595; yet even after that time were often harassed by the incursions of the Kirghises and Soongares; the latter of whom compelled them to pay an annual tribute. Since the

Siberian frontier line was properly defined, they have enjoyed complete tranquillity, under the protection of the Russians. They number about 5000 bows. Most of them have abjured Paganism, and embraced the religion of Mahomet. See *Voyages de Pallas*, octavo, tom. vi. p. 436, &c. Tooke's *Viva of the Russian Empire*, vol. i. p. 180; vol. ii. p. 64. (u)

BARBADOES, the most windward of the West India islands, and one of the principal of those belonging to Great Britain. It is supposed to have been first discovered by the Portuguese, in the course of their voyages from Brazil, and was then totally uninhabited. They did not make any settlement on this island, but having furnished it with a breed of hogs, for the benefit of such of their countrymen as might navigate the same tract, they left it in the situation in which they found it. The first of the English who are known to have visited Barbadoes were the crew of a ship from London to Surinam in 1695. Finding it without inhabitants, they took possession of the country by fixing a cross on the spot where James Tower was afterwards built, and they put on it the following inscription: "James, king of England and this island." The English did not, however, form any settlement in Barbadoes until 1624, when a few adventurers, under the patronage of the earl of Marlborough, to whom James I. had made a grant of the island, arrived upon it, and laid the foundations of the tower, which still retains the name of that prince. The claims of this nobleman, however, were disputed by the earl of Carlisle, who received a general grant of all the Carribean islands from Charles I. After some time, the latter nobleman became the sole proprietor of the island; but in 1663 the family gave up the patent, on condition of receiving a permanent and irrevocable grant of $4\frac{1}{2}$ per cent. on the produce of the island exported to other parts of the world; a burden which, according to the agreement, still falls upon the colonists. The planters, though they felt the disadvantage of the proprietary government, were driven into this measure by the crown. The conduct of the Lord Chancellor Clarendon, in promoting it, was afterwards thought so justly reprehensible, as to form one of the articles of impeachment brought against him by the house of commons in 1667.

This island, according to Mr Edwards, is about 21 miles in length, and 14 in breadth, and contains 106,470 acres, most of which are in a state of cultivation. The soil near Bridgetown, and in the low parts of the country, is formed of a rich black earth, spread on a base of calcareous rock, formed of madripores and other marine concretions. In some districts the soil is of a red earth, of greater depth, but inferior in richness; in others it is of a light whitish earth, broken into a grey mould, or hardened into lumps resembling chalk, but actually consisting of indurated argilla, bleached by exposure to the weather. Of this variety of soil, the black mould is best suited for the cultivation of the cane, and with the aid of manure has afforded as great returns of sugar, in favourable seasons, as any in the West Indies, the prime lands of St Kitts excepted. As this island has been long under cultivation, the soil is supposed to be now much exhausted. In order therefore to supply it with manure, we find that great herds of a species of small cattle, chiefly steers, are kept on the plantations principally for this purpose. These are employed instead of horses, in the heavy labours of the estate; and it is common to see from twelve to twenty-four of them

in a waggon, drawing a single hogshead of sugar, or some other small load, which in this country would be conveyed with facility by two horses in a cart. In consequence of such numbers of cattle being necessary to furnish manure for the land, there is a greater supply of beef and veal in their markets, and fresh provisions are more abundant on this island, than in most of the other colonies. The animals, according to Dr Pinckard, are brought alive into the market, to be killed after the different joints are sold; and it often happens that the meat is slaughtered, dressed for dinner, brought to table, and used by the guests without growing cold.

In consequence of the general cultivation of this island, and its full exposure to the trade winds, the temperature of Barbadoes is more equal, and the air more salubrious, than in most other parts of the West Indies. Indeed it is considered as the most healthy of all the islands, so that it is common in sickness to make a voyage from the other colonies to Barbadoes, as the Montpellier of this quarter of the globe. When Dr Pinckard was in this country, the thermometer placed in the shade in the harbour was seldom higher than 84° , and at no time did it exceed 86 degrees. But though this island is blessed with exemption from excessive heat, from noxious vapours, and from general sickness, it is visited by a malady so much its own, as to have obtained the appellation of the *Barbadoes disease*. It appears in the form of elephantiasis, or what is here termed the glandular disease, and is a peculiarly unsightly and distressful malady.

This island, after the settlement of the English upon it, appears to have rapidly attained a most flourishing state. We are assured that about the year 1670, there were nearly 50,000 whites, and 100,000 blacks, on this small spot, being upwards of five hundred to every square mile, a population superior even to that of Holland or China. About this time, the trade of Barbadoes is said to have employed 400 sail of ships, which conveyed about 60,000 tons. The annual exports in sugar, indigo, ginger, cotton, and citron water, amounted to upwards of 350,000*l.*, and the circulating cash at home was about 200,000*l.* But though this account is probably much exaggerated, it cannot be doubted that the population of Barbadoes has rapidly decreased after that time, as appears from the following returns which were made of the inhabitants at different periods during the last century:

	Whites.	Blacks.
1724 . .	18,295 . .	—
1753 . .	— . .	69,870
1786 . .	16,167 . .	62,953

Among the inhabitants of this island, there is a numerous class between the great planters and the people of colour; a circumstance which forms a striking difference between Barbadoes and the other colonies. Of them many are descended from the original settlers, and have no precise knowledge when their ancestors first arrived. They accordingly regard this island as their nation and only abode, and do not, like the planters or the negroes, look back to the scenes of infancy as their better home.

We are informed by Mr Edwards, that the annual produce of this island had decreased during the last century, in a much greater proportion than in any of the other islands: but previous to the war with France, the planters appear to have extended the cultivation of sugar, in consequence probably of the advances upon that

article in Europe. In 1736 the crop of sugar amounted to 19,800 hogsheads, of 15 cwt.: but after this period, it fell to nearly one half of this quantity, and did not be-

gin to increase until about the period of the French revolution, as appears from the following account of the principal exports from this island at different periods:

Years.	SUGAR.			MOLASSES		RUM.			GINGER.	ALOES.			COTTON.

The number of slaves imported into this island, from 1786 to 1792, amounted to 4481, so that at the latter period there were 64,330 upon the island. In 1792 the public taxes, exclusive of the duty of the $4\frac{1}{2}$ per cent. on exports of native produce, amounted to 9443*l.* 19*s.* 3*d.* which was nearly the average of them during the preceding six years.

According to a statement given by Mr Wilberforce in the House of Commons, in the course of the investigation of the slave trade, the number of slaves on this island was as follows.

In 1764 about	70,706
1774 . . .	74,874
1780 . . .	68,270
1781 . . .	63,248
1786 . . .	62,115

This island is divided into five districts, and eleven parishes, and contains four towns, namely, Bridgetown, Charlestown, St James's, and Speight's town. Bridgetown, the capital, has one of the finest harbours in the West Indies, and before it was destroyed by the fire of 1766, consisted of about 1500 houses, which were mostly built of brick. It had scarcely risen, however, from the ashes to which it was reduced, when it was torn from its foundation, and the whole country made a scene of desolation, by a dreadful storm in 1780, in which no less than 4326 of the inhabitants miserably perished, and the damage to the island was computed at 1,320,564*l.* sterling. Bridgetown is the residence of the governor, whose annual salary was raised by Queen Anne, from 1200*l.* to 2000*l.*, which is paid out of the exchequer, and charged to the account of the $4\frac{1}{2}$ per cent. duty. The form of the government of this island resembles that of Jamaica, except that the council is composed of twelve members, and the assembly of twenty-two. The most important difference is with regard to the court of chancery, which in this island is composed of the governor and council, whereas in Jamaica the governor is sole chancellor. On the other hand, in Barbadoes the governor sits in council, even when the latter are acting in a legislative capacity, which in Jamaica would be considered as improper and unconstitutional. It may also be observed, that the courts of grand sessions, common pleas, and exchequer, in Barbadoes, are distinct from each other, and are not united in one supreme court as in Jamaica. Barbadoes is situated in West Long. 57°, and North Lat. 13° 10'. See Raynal's *History of the European Settlements in the East and West Indies*, vol. 5. Edwards' *History of the British Colonies in the West Indies*, vol. i. Pinckard's *Notes on the West Indies*, vol. i. and ii. Clarkson's *History of the Abolition of the Slave Trade*, vol. ii. p. 71. Poyer's *History of Barbadoes*. Ligon's *History of Barbadoes*. Hughes' *Natural History of Barbadoes*. Gray's *Letters from Canada*, 1809, p. 379. Thownes, *Collect. Acad. Par.* tom. iv. p. 79. (w. B.) (π)

BARBAROSSA, HORUC, who received his name from the red colour of his beard, was the son of a potter in the island of Lesbos, and must have been born about the year 1474. Animated by a restless and enterprising spirit, he forsook his father's trade when he was little more than thirteen years of age; and, together with his two younger brothers, Hayradin and Isaac, joined a crew of pirates. Distinguishing himself by his valour and activity, he soon acquired the command of a small brigantine, which had been fitted out by a

merchant of Constantinople, to cruise against such nations as were not in alliance with the Porte. He steered directly to the coast of Barbary, and was well received by the king of Tunis, who permitted him to put into any of his ports, upon condition of his paying a tenth of every prize; and to whose subjects he was a very profitable guest, both by the sale of his booty, and the prodigality of his crew. He was so successful in his piratical excursions, that in little more than the space of eight years he saw himself, with his brother Hayradin, who was second in command, at the head of twelve galleys, and several smaller vessels, well manned with Turks and Moors. "Together with their fame and power," says Dr Robertson, "their ambitious views opened and enlarged; and, while acting as corsairs, they adopted the ideas, and acquired the talents, of conquerors." They were particularly desirous of forming an establishment in Barbary, on account of the convenient situation of its harbours, which lay so near to the greatest commercial states at that time in Christendom; and they did not suffer to pass unimproved some favourable opportunities which occurred, for accomplishing their object. Invited to assist the king of Biyeyah in recovering his capital from the Spaniards, they entered keenly into the expedition against the city; but were repeatedly foiled in their attempts, in one of which the left arm of Horuc was carried away by a cannon ball. In the mean time he ingratiated himself so much with the inhabitants of Jigel, by supplying them with corn in a time of famine, that they invested him with the title of their Sultan, and assisted him in reducing the neighbouring mountaineers. While thus actively employed in enlarging his territories and extending his fame, he received an embassy from Eutemi king of Algiers, requesting his aid against the Spaniards. Pleased with the prospect, which was thus presented, of acquiring a more convenient and important station on the African coast, he dispatched his brother Hayradin to Algiers, with eighteen galleys and thirteen barks; and himself advanced by land, with 800 Turks, 3000 Jigelites, and 2000 Moorish volunteers. He stopped at Sher-shel on his way, where another celebrated pirate, named Hassan, had established his power; and having perfidiously put him to death, he seized his ships, and compelled his adherents to join in the expedition to Algiers. Upon his arrival in that city, he was hailed by Eutemi and his subjects as their deliverer, lodged in the most splendid apartments of the palace, and treated with the highest marks of distinction. Inflamed with ambition, he soon aspired to the sovereignty of the country which he had been invited to protect; and possessed of the power to accomplish his object, he was very little scrupulous as to the means. He secretly murdered the unsuspecting monarch, who had sought his assistance; compelled the Algerines to acknowledge him as their king; and established his authority by the most sanguinary proceedings. Selim, the son of Eutemi, supported by the Spaniards, attempted to recover the throne of his father; but the Spanish fleet, which had come to his assistance with 10,000 troops on board, was dispersed by a storm, and the greater part of the ships wrecked upon the coast. The neighbouring Arab tribes, alarmed by the success, and irritated by the encroachments of Barbarossa, solicited Hamidel Abdes, king of Tenes, to assist them in expelling from Algiers such a formidable neighbour; and in hopes of acquiring the sovereignty of that country for himself, he boldly advanced to the

contest with 10,000 Moors, and a crowd of Arab troops. But the intrepid Barbarossa, with 1500 musketeers, easily routed this numerous army, which was armed only with javelins and arrows; pursued Hamidel to the gates of his capital; and soon made himself sovereign of Tenes. Leaving his brother Isaac governor of that city, he marched into the country of Tremecen, at the request of the inhabitants, to assist them to expel their reigning prince Abuzijon, who had usurped the sovereignty from his nephew Abuchen-Mon. By means of his artillery, he was again victorious over an enemy superior in numbers; and the defeated prince having been put to death by his disaffected subjects, Barbarossa was invited to take possession of the kingdom. Having alienated his new subjects, however, in a very short time, by his oppressions and extortions, they began to form schemes for the restoration of Abuchen-Mon; and that prince, having taken refuge in the Spanish fort at Oran, had found means to interest the Emperor Charles V. in his cause. The Marquis of Gomarez, with 10,000 men, was commanded to reinstate Abuchen in his dominions; and being joined by Selim, the son of Eutemi, with a number of Moors and Arabs, they advanced to besiege Barbarossa in Tremecen. Obligated by the revolt of the inhabitants to retire to the citadel, he defended himself there with the greatest vigour, to the last extremity; but, his provisions beginning to fail, he made his escape by a subterraneous passage, and attempted to retard the pursuit of his enemies by strewing his treasures in the way. Overtaken by the activity of the Spanish general about eight leagues from Tremecen, and overpowered by superior numbers, his Turks were cut in pieces to a man, and he himself was slain, while fighting with the most determined valour. Thus perished this noted corsair in the 44th year of his age, about four years after he had obtained the sovereignty of Jigel, two years after being acknowledged king of Algiers, and scarcely a twelvemonth after the acquisition of the kingdom of Tremecen. (g)

BARBAROSSA, HAYRADIN, upon receiving intelligence of the defeat and death of his brother Horuc, assembled the Turks together in Algiers, to consult as to the most proper measures of safety. Aware of the well-grounded aversion, which the Algerines had always entertained towards their government, and alarmed by the strength of the Spanish army in their neighbourhood, they proposed at first to embark their troops and their plunder, and entirely to abandon the city of Algiers. But the Spanish commander, instead of pursuing his victory, having withdrawn the greater part of his forces from Africa, Barbarossa's adventurers were encouraged to keep their station, and he was instantly proclaimed king of Algiers, and high admiral of the sea. Perceiving, however, the growing impatience of the Arabs under his government, and having discovered symptoms of immediate insurrection, he put his dominions under the protection of the Grand Signior, received the title of viceroy or bashaw of Algiers, and was furnished with ample means of defence against all his enemies. He applied himself with the utmost vigour to fortify his capital, to improve his harbour, and to increase his navy. He reduced the Spanish fortresses in his neighbourhood, overawed the adjoining Arab tribes, and carried on the most daring depredations against all the maritime powers of Europe. At length, A. D. 1533, partly as a reward for his great services, partly from

jealousy of his growing power, and partly on account of his eminent talents as a naval commander, Solyman I. called him from the government of Algiers, and placed him at the head of the Turkish marine, as the only person in his dominions capable of opposing the celebrated Andrew Doria, the admiral of Charles V. and the greatest sea officer of his age. "Proud of this distinction," says Dr Robertson, "Barbarossa repaired to Constantinople; and, with a wonderful versatility of mind, mingling the arts of a courtier with the boldness of a corsair, gained the entire confidence both of the Sultan and his Vizier." He was accompanied to the Ottoman court by Ahraschid, prince of Tunis, who had solicited his support against his younger brother Muley Hascen; and he communicated to Solyman a treacherous plan which he had formed of annexing Tunis to the Turkish empire, by using the name and influence of the exiled prince. Ahraschid was shut up in the seraglio, and never heard of more. Barbarossa, who pretended to have him on board his galley, sailed to Tunis with a fleet of 250 vessels; got possession of the place by means of that prince's adherents; and then compelled the inhabitants to acknowledge Solyman as their sovereign, and himself as his viceroy. Having completely established himself in his new kingdom, he renewed his piracies against the Christian states to so great an extent, and with such savage barbarity, that at length the emperor Charles V. roused by the daily complaints of his outrages, and moved by the entreaties of the exiled Muley Hascen, resolved to deliver Europe from the scourge of his depredations, and putting himself at the head of a powerful fleet and army, he sailed for Tunis in the month of July 1535. Barbarossa, on his part, was both prepared and determined to make a vigorous defence; but he was unable to withstand the deliberate courage and discipline of his assailants. His strong fortress of the Goletta was taken by assault after a desperate resistance; his army was defeated in spite of all his exertions, within sight of his capital; the guns of the citadel were turned against him by the Christian captives, who had gained their liberty during his absence; and he saved himself with difficulty by a precipitate flight to Bona. (See a more detailed account of the preceding events in the article ALGIERS.) Having returned to Constantinople, he was again appointed to command the fleets of Solyman, and was employed in various important expeditions; in the war against the Venetians in 1537, in the invasion of Arabia Felix in 1538, and in an attack upon the islands of the Archipelago in 1539. In 1543 he scoured the coast of Calabria with a fleet of 110 galleys; took and plundered the city of Reggio; advanced to the mouth of the Tiber, to the great terror of the inhabitants of Rome and the neighbouring country; sailed to join the French fleet at Marseilles, and then directed his course to the city of Nice; was there repulsed with considerable loss, and at length obliged to retire upon the approach of Doria to its relief. After ravaging the coasts of Naples and Tuscany, he returned to Constantinople in 1544; and continued to direct the naval affairs of the Ottoman empire till the year 1547, when he died of a sudden fit of sickness about the 70th year of his age. See Robertson's *Hist. of Charles V.* vol. ii. p. 56, &c. 153. *Mud. Univ. Hist.* vol. xviii. p. 262. &c. 427. Mignot's *Hist. of the Ottoman Emp.* vol. i. p. 363; vol. ii. p. 18, 22. (g)

BARBARY.

BARBARY, the most northern division of Africa, is bounded on the north by the Mediterranean, on the south by Sahara or the Desert, on the east by Egypt, and on the west by the Atlantic Ocean. Its utmost extent from east to west, from cape Non on the coast of Morocco, to Alexandria on the confines of Egypt, is nearly 40°, (from the 10th W. to the 30th E. Long.) or about 2760 geographical miles. Its breadth in a direct line from north to south, is very unequal, and may be variously estimated, according to the portion of the desert which may happen to be included; but at the widest parts, it can scarcely be reckoned more than 8 degrees, or 556 miles, while at the narrowest point it is not above 2 degrees, or 159 miles. It commences on the west, where Mount Atlas approaches the Atlantic, stretches along the coast in a north-east direction to cape Spartel, and thence proceeds with various windings, but chiefly in an easterly course, along the shores of the Mediterranean to the city of Alexandria.

Various conjectures have been formed respecting the origin and import of the word *Barbary*. Some have derived it from the general appellation Barbarians, which the Romans, when they conquered the country, are supposed to have applied, by way of eminence, to the inhabitants of North Africa. Others suppose it to have originated with the Arabian conquerors, in whose language "barbar" signifies a murmuring noise, and who are understood to have given this name to the country, because the language of the natives appeared to them at first as merely an inarticulate, muttering sound. Others, again, have considered it as nothing more than a repetition of the Arabic term "bar," which signifies a desert; and ascribe its origin to the following circumstance,—that, when king Ifrick, in his flight from Arabia Felix, was hesitating which course to take, his attendants exclaimed, "bar, bar!" to the desert, to the desert! It has, last of all, been deduced from the word Berber or Berebber, signifying barren, a name, which is supposed to have been appropriated to the north Africans, on account of the barrenness of their soil, and which is still retained by the inhabitants of the mountainous districts of Barbary. But the word Berebbers denotes also shepherds; and the shepherd tribes who were expelled from Egypt, are conjectured to have taken refuge in Abyssinia and northern Africa: hence, according to Mr Bruce, Barbary may be equivalent to Barbaria, or Berberia, "the country of the Berebbers," that is, of the shepherd race.

The ancient history of Barbary will be found more at large, under the articles NUMIDIANS, MAURITANIANS, CARTHAGINIANS, ROMANS, and the other nations by whom it was formerly inhabited, or to whom it was successively subjected. It is conjectured, with sufficient probability, that this country received its first inhabitants from Egypt, and that it was afterwards colonized by the Phenicians. By this enterprising people the cities of Utica and Carthage were founded; and as the Carthaginians increased in wealth and power, they either reduced or rendered tributary most of the other states in the north of Africa. Upon the fall of Carthage, B. C. 144, the greater part of those provinces of which Barbary now consists, became subject to the Romans, and continued under their government till the year of Christ

428. About this period, the Vandals under king Genseric began to make incursions from Spain into Africa; and before the year 455, rendered themselves complete masters of all that the Romans had possessed in that quarter of the globe. These savage conquerors gave the first fatal blow to the prosperity of northern Africa, and reduced its most flourishing cities to a state of desolation, from which they have never recovered. The noblest monuments of Roman grandeur were converted into heaps of ruins; while the miserable inhabitants were involved in the most relentless persecutions. About the year 530, the power of these barbarous invaders was completely overthrown by the renowned Belisarius; and Barbary remained under the dominion of the Greek emperors, till towards the end of the 7th century, when it was overrun by the resistless arms of the Mahometan Arabs, and formed a part of that vast empire of which the caliphs were the head. Its great distance, however, from the seat of government, encouraged its rulers to assert their independence; and the caliphs were often obliged to connive at acts of rebellion which they were unable to prevent. In this manner, Barbary was gradually divided into a number of petty kingdoms, continually at war with each other, and continually varying in their extent. It was the scene of many sanguinary revolutions, and was ruled by several succeeding dynasties, whose history is very imperfectly known, and scarcely deserving of a particular detail. It continued in this unsettled and neglected state till the beginning of the 16th century, when the rise of the piratical states under the Barbarossas, (See ALGIERS and BARBAROSSA,) rendered it at once more formidable and better known to the nations of Europe. Since this last mentioned æra it has been frequently visited by travellers, and described by a great variety of authors; but it must still be considered as a country with which we are very imperfectly acquainted. This may be ascribed chiefly to the very short and rapid visits which Europeans in general make to this country; to the superficial knowledge which they possess of the language of the inhabitants; to the watchful jealousy with which foreign residents are regarded by the governments; to the bigotted and bloody antipathy which the natives entertain towards the subjects of Christian states; and to the incalculable hazards to which travellers are exposed from the plundering Arabs, against whose ferocious cupidity even the authority of the princes can scarcely afford sufficient protection.

The country of Barbary, as has been already mentioned, soon after its subjection to the caliphs, was divided into a multitude of petty sovereignties; but these have been so continually varying, both as to their particular number and relative strength, that it is impossible either to enumerate or describe them with any tolerable degree of accuracy. The chief of them at present are, Morocco, Algiers, Tunis, Tripoli; and to one or other of these, the smaller kingdoms of Fez, Tremecen, Constantina, Barca, &c. are now become subject. The largest of these, Morocco and Fez, comprehending the greater part of west and south Barbary, forms an entire and independent empire of itself. The more northern and eastern states are still in some degree dependent upon the Turkish power, or at least

occasionally claim its protection. For a separate account of whatever may be peculiar in each of these divisions, with respect to history, description, government, population, &c. we refer the reader to the several articles ALGIERS, MOROCCO, TUNIS, TRIPOLI, &c.; and shall here endeavour to collect and arrange, in one view, such observations as apply to the country and inhabitants of Barbary in general.

The climate of Barbary is, in general, peculiarly temperate and salubrious, equally removed from the opposite extremes of drought and moisture, of heat and cold. In the coldest seasons the thermometer seldom sinks more than to the 5th degree above the freezing point, and in the warmest weather it seldom rises to sultry, except when the winds blow from the Sahara. During a long residence in Morocco, M. Chenier never observed it lower than $2\frac{1}{2}$ above the freezing point; and during the space of 12 years at Algiers, Dr Shaw found it so low as freezing only on two occasions, when the ground was covered with snow. According to the observations of the last mentioned author, all the variations of the atmosphere, as indicated by the barometer, are comprehended within the compass of $1\frac{3}{10}$ inch, or from $29\frac{1}{10}$ to $30\frac{4}{10}$. The air upon the coast is nearly as cool during summer, as in the most temperate countries of Europe; and, even in the more inland places, the heat is greatly moderated by refreshing breezes from the snowy summits of the Atlas mountains. In the southern provinces, however, during the months of July and August, the heats are sometimes extreme; and, about the beginning of September, a suffocating wind from the Sahara, called the *Shume*, or *Siume*, blows with the greatest violence for the space of one, two, or even three weeks. During the prevalence of this parching blast, the ground is often heated to such a degree, that it is almost impossible to walk upon it; and the inhabitants are obliged to retire to subterraneous apartments, or warehouses on the ground floor, eating nothing but fruits, and frequently sprinkling their houses with vinegar to cool the air. Buckets of water, also, are thrown upon the stone-walls of the bed-chambers, to render them habitable towards night; and so excessive is the heat, that the effect of this operation is often similar to that of casting water upon hot iron. During the dry season, from March to September, it scarcely ever rains; and the atmosphere is almost completely free of clouds: even during the rainy season, from September to March, there is seldom a day that the sun is not visible at intervals. These vernal and autumnal rains are remarkably regular, and seldom violent; but the country is occasionally subject to long-continued droughts, which never fail to produce innumerable swarms of locusts, the most destructive enemies of vegetation, and the frequent forerunners of famine.

The general appearance of the country is rather mountainous, tolerably covered with wood, but not so well watered. In many places it is finely varied in hill and dale; and amidst the forests and higher grounds, the most delightful retreats are to be found, refreshed with abundant and numerous streams, filled with odiferous plants and flowers, and yielding the most luxuriant and nutritious herbage. The soil, especially towards the coast and in the mountainous districts, is light and sandy, of a very loose and yielding texture; but, in some of the northern provinces, it is composed of a rich black or red earth, without either clay or stone. It is capable of every kind of cultivation, and is productive in the

highest degree. In the northern districts, it is well fitted for the growth of the most valuable European productions; and in the southern, it is capable of yielding every luxury peculiar to the East or West Indies. It is, in general, strongly impregnated with various salts; and to this circumstance, it is conjectured, may in a great measure be ascribed that extraordinary fertility for which it has always been remarkable. The culture, which it receives, is meagre and superficial in the extreme. The only manure, which is employed, is the annual burning of the long stubble, and the dung of the cattle turned out to pasture; while all the tillage that is bestowed is a slight scratching, about six inches deep, which is frequently performed with a wooden plough, and of which an ordinary pair of bees is sufficient to accomplish a whole acre in one day. Two bushels and a half of wheat or barley are usually sown upon one acre; and the ordinary produce is about 12 bushels for one. A much greater increase, however, is not uncommon. One grain generally puts forth ten or fifteen stalks, sometimes fifty or sixty, and in some instances even a still greater number. Each of these stalks sometimes bears two ears, and these again often shoot out into a number of smaller ones, so as to afford a most extraordinary return. After the custom of the East, the natives of Barbary tread out their corn by driving the cattle over the sheaves spread out on some level spot of ground, and then separate the chaff, by throwing it up against the wind with a shovel. The grain is then lodged in *mattamores*, or subterraneous magazines, containing at least 400 bushels each, lined with straw, and covered with earth in a pyramidal form. In these store-places it can be preserved, without suffering any damage, for the space of five or six years, and even for a much longer period. The horticulture in Barbary is, if possible, even more deficient than the husbandry; and the gardens are neither laid out with taste, nor kept with care; but present to the view a confused mixture of fruit-trees, pot-herbs, and grain, neither divided by walks, nor ornamented with flowers. Yet even with this superficial cultivation, the soil of Barbary yields almost every vegetable production in the greatest abundance; and were the husbandman sufficiently protected in the exercise of his labour, and the enjoyment of his gains, it is supposed to be capable of producing a hundred fold more than the consumption of its population requires.

The natural productions of this country are of great variety and value, well suited to the wants of the natives, and amply sufficient to supply a large exportation. The principal kinds of grain cultivated here are, wheat, barley, Indian corn, rice, millet, pease, beans, caravances. No oats are to be found in Barbary; and the usual provender of the cattle is barley and cut straw. Hemp, flax, cotton, and, in some districts, tobacco, are raised in considerable quantities. Apples, pears, apricots, plumbs, pomegranates, cherries, dates, almonds, and all the fruits produced in the south of Portugal and Spain, are found in this fertile country. Melons, oranges, lemons, limes, figs, grapes, strawberries, and a multitude of similar refreshing fruits, are supplied to the natives of northern Africa, often indeed of an inferior quality, but generally in the greatest profusion. The sugar cane grows spontaneously in some places, stick liquorice in amazing quantities, a variety of useful gums, and different kinds of medicinal herbs, such as wormseed, orris-root, coloquinth, &c. There are

every where along the coast, plantations of olive trees, which grow to a considerable size; the argan tree, which bears a fruit resembling the walnut, yielding an excellent oil; large forests of oak, and corkwood; and a peculiar tree called arar or sandrac. (supposed to be the *arbor vite* of Theophrastus.) remarkable for its property of resisting the rot, and the worm. Honey and wax, also, though not strictly speaking vegetable substances, may here be mentioned, as forming no despicable part of Barbary produce.

The prevailing mineral in this country is salt, which seems to pervade the whole soil, and of which there are innumerable pits, rocks, and springs. Salt-petre, also, is extracted in great quantities, from the earth of certain districts; and many sulphureous fountains, some temperately warm, and others intensely hot, are found in different parts of the country. There is very little stone of any kind fit for building; and though the Numidian marble is highly celebrated by the ancients, (*Plin.* l. 5. c. 3.) none of it has been observed in modern times. Several crystals and spars, specimens of talc, mica, and pyrites, and a great variety of petrefactions, have been noticed by travellers. There are mines of iron, lead, copper, silver, antimony, and a mixed ore of antimony, lead and gold, in the mountainous districts; but only the three first mentioned metals are wrought to any great extent.

Barbary is richly stored with all the various classes of animated nature; and its domesticated animals have long constituted the most valuable possessions of the inhabitants.

The *horse*, formerly the distinguishing glory of Numidia, is now greatly degenerated. When the Arabs found, that the best of their stud were generally seized and carried off by their Turkish despots, they soon began to neglect the improvement of the breed; but those of West Barbary are still very much renowned for their fleetness and activity. They have, in general, a stronger sinew than the European horses; and, after a little training, become extremely manageable. They are taught to have only two paces, a walk and a gallop; to stop short suddenly, when checked at full speed; and to stand still, whenever the rider may choose to quit them. Except among the Shelluh tribes, the mares are kept for breeding, and the stallions only used for riding. The *ass* and *mule* of this country, though not equal in size and beauty to those of Spain, are very hardy and serviceable creatures, requiring little attendance, and generally employed both in riding and bearing burdens. The *kumrah* or *jumar*, a small animal, the offspring of the ass and the cow, has also been mentioned as a native of Barbary; and Dr Shaw has described one which he saw at Algiers, and which, he remarks, was not regarded there as an uncommon spectacle. But Mr Jackson, in all his travels in the west of Barbary, never saw such a creature, or found any person who had seen it, though he was informed that it was sometimes seen in Biledulgerid; and its existence is still considered by many naturalists as very questionable. The *cows* are small, and yield very little milk, seldom more than a quart at a time; but their flesh is tender and well tasted. *Sheep* are to be found in all parts of Barbary; and, owing to the abundance of aromatic herbs in the pasturage, the mutton possesses a peculiarly fine flavour. There is a species of this animal very common in the eastern districts, which have immense tails, containing a hard, solid fat, which is greatly esteemed by the natives, and

which bears a near resemblance to marrow. On the confines of Sahara is another species, similar in shape and size to the fallow deer; but their flesh is dry, and their wool of a bad quality. The wool, indeed, of this country varies considerably; some of it is as coarse as hair, and some again as soft and fine as silk. The *goats* of Barbary are extremely prolific, and their exportation forms a considerable article of commerce; but they are chiefly valued on account of the leather, which is prepared from their skins. The *camel* is unquestionably the most useful animal in this quarter of the globe, on account of its well known capacity of enduring the utmost fatigue, and at the same time requiring a small proportion of nourishment. It can travel four or five days without water; can subsist for 24 hours upon one half gallon of barley and beans, or a few balls of flour; and can carry a load of seven or eight quintals, travelling 10 or 15 hours in the day, at the rate of 2½ miles in the hour. *Dromedaries* are more rare in Barbary than camels, and are generally brought from Guinea or Arabia. They are remarkable for the swiftness of their motion; and there is a particular species of this animal, which, both Dr Shaw and Mr Jackson assure us, will go over more ground in one day than the fleetest horse can go in 8 or 10. It is called the *heirie* or *desert camel*; and of this extraordinary animal the last mentioned gentleman has given a most interesting description, to which we must refer our readers. We may merely inform them, that this creature is guided by a leathern thong, attached to a ring, put through its upper lip; that it can travel, on an emergency, seven days without water; that there are three kinds, varying in excellence and value,—the *telayee*, that is, performing in one day a journey which employs a horse three days, and one of these is equivalent to the price of 30 camels,—the *sebayee*, which travels seven days journey in one, and which are worth 100 camels,—and the *tasayee*, nine days journey in one, which are extremely rare, and which are worth 200 camels. The *desert horse*, called *Sh'rubah Er'reeh*, signifying *wind sucker*, (because the animal when in speed, hangs out his tongue as if sucking the air,) bears the same relation to the common horse, that the desert camel does to the camel of burden. His body is slender like that of a greyhound, his legs small, and his chest very broad. He is used chiefly in hunting the ostrich; but is not so well calculated for crossing the desert, as he lives entirely on camel's milk, and therefore needs to be accompanied by two she camels in such long excursions.

Among the *wild* quadrupeds of Barbary may be mentioned the large herds of horned cattle of the *neat* and *deer* species, which abound in the mountainous districts; and of which one of the most remarkable is the *Fishtall* or *Lerwee*, as it is called by Dr Shaw, or the *Aoudad*, according to Mr Jackson. It resembles a young heifer of about a year old; has a long mane or beard from the lower part of its neck; resides in the most inaccessible places; throws itself headlong over lofty precipices when pursued, generally falling on its horns or shoulders; is very seldom caught, and is not to be approached without great danger. The *rhinoceros*, whose horn is capable of receiving a very high polish, and is sold in Barbary at an enormous price. The young of this animal have only one horn, till a certain age; and as one of its Arabic names is very similar in sound to the word which signifies a mare, it has been conjectured, that from this circumstance may have arisen, by mistake, the notion

of the Unicorn. Among many other animals, not very well known in Europe, may be mentioned the elegant black-eyed *gazel*, or *antelope*, which is remarkably swift and timid; the *horreh*, a smaller kind of antelope, the emblem of cleanliness, as its name imports, celebrated for the brilliant whiteness of its belly, for the preference given to its skin, by the Moors of distinction, as the fittest substance upon which they can prostrate themselves in prayer, and for the concretion found in its testicle or stomach, called the besoar stone, so much valued as an antidote against poison; the *thaleb*, or little red fox, which is very destructive to the young vines, and remarkable for its shrill and piercing cry; the *sib-sib*, an intermediate species between the rat and squirrel, accounted by the Arabs a great delicacy, and the only animal which the Mahomedans torment with a view to improve the taste of its flesh; the *ape*, which is seen in great numbers, and found of a very large size in North Atlas; besides the *deeb*, or jackal, *jerboa*, porcupine, hare, rabbit, weasel, &c. Of the more ferocious wild animals, the chief are the *lion*, the *leopard*, the *panther*, which are all occasionally ravenous invaders of the Arab encampments, and sometimes even infest the roads, in the neighbourhood of large towns; the *wild boar*, whose strength is here proverbial, but which seldom attacks men, unless he be previously roused by some provocation; the *hyæna*, or *dubbah*, which, in Barbary, is more stupid than fierce, and whose flesh, as it is asserted by the Arabs, occasions a temporary stupefaction; the *wild cat*, which is large and strong, and, when pressed with hunger, will sometimes attack the traveller with great ferocity; the *bear*, or *dubb*, is very seldom seen, and inhabits only the upper regions of Atlas, which are continually covered with snow.

Domestic *fowls*, *house-pigeons*, and *sparrows*, resembling those of Europe, are remarkably plentiful in Barbary. There is a great variety of the *duck* species, but the common *geese* and *turkeys* are seldom seen. The towns, in the summer season, are much frequented by *storks*, which are treated with great veneration by all Mussulmen, as being emblematical of conjugal affection, and also as being very destructive to many noxious reptiles. Among the wild fowl, may be mentioned wood-pigeons, wild geese, herons, bustards, flamingoes, pelicans, plovers; *partridges*, which are much larger and finer feathered than those of Europe; *curlews*, which are found in great abundance; *cuckoos*, which are esteemed a great delicacy by the Arabs; *wood-cock*, which, from the largeness of its head, is called by the natives, *the ass of the partridges*; *cl hage*, a small cinereous-coloured bird, which lives upon insects of the beetle kind, which it sticks upon thorns, and does not eat till they begin to putrify: It has its name from the circumstance of its accompanying the caravans which go to Mecca. The *crow* of the desert is a beautiful bird, somewhat larger than the common raven, with the legs and bill of a red colour. The *ostrich* abounds in the confines of Sahara; and those which are taken near Cape Bojador are of the largest size, and have the finest plumage of any in the world. There are also various kinds of singing-birds in this country, the lark, the nightingale, the thrush, the starling, the blackbird, and especially the *capsa sparrow*, which is larger than the common sparrow, and coloured like the lark, which has a very sweet and melodious note, superior to that of the canary bird, or of the nightingale, but which is so pe-

culiarly delicate in its temperament, that it soon pines away in the smallest change of climate. Among the birds of prey in North Africa, the most deserving of notice are the *nessor*, or *vulture*, which, next to the *ostich*, is the largest bird in that quarter of the globe, and which feeds chiefly upon the horned beetle, that is found upon the gum-ammoniac plant; and the *eagle*, the largest species of which has an exceedingly clear and beautiful eye of an orange colour, and is the bird, as the Africans believe, which engenders the dragon upon the female hyæna.

On the coasts of Barbary is found the greatest abundance of excellent fish, particularly mullet, brim, anchovies, sardines, herring, mackarel, cod, skate, soles, plaice, turbot, turtle. A very firm and well-tasted *barbel*, *eels*, and *shebbel*, are very common in the rivers, the last mentioned of which is similar to the salmon, and is extremely rich and delicate. Immense quantities of it are salted or baked, and sent into the interior of the country, where it is considered as an excellent corrective of the bad effects sometimes produced by an immoderate use of dates. *Whales* have occasionally been cast ashore on those parts, which are washed by the Atlantic, but very rarely on the coast of the Mediterranean, and, in these cases, considerable quantities of ambergris are generally found along with the stranded fish. There is not much shell fish on these coasts. Shrimps, prawns, crabs, and cray fish, indeed, are not uncommon. *Oysters* also have been found near Algiers; and the *muscles* there are both very excellent and abundant. Land *tortoises* are of a good quality, and of a very large size, sometimes weighing between four and six cwt.; but the inhabitants do not use them as food, and seldom catch them, except when employed by the Europeans for the purpose.

In the country of Barbary the insect tribes are extremely numerous, of a great variety of shapes, and remarkable brilliancy of colours. There are butterflies, libellæ, and beetles, three inches in length, and four inches between the extremities of the wings, when extended. The most remarkable of the beetle species is the *dibben fashook*, which has a long horn proceeding from the upper part of its mouth, with which it perforates the ammoniac plant, and makes the incisions from which the gum oozes out. The *cicada* or *cricket* is of a very large size, and makes an incessant piercing noise during the night. The *gnats*, or *mosquitoes*, are extremely numerous, especially on the banks of lakes, and are very keen in their attacks upon Europeans; but the thick skins of the Arabs, exposed daily to the scorching heat of the sun, are impenetrable to their bite. But of all the insects of Barbary, the most formidable and abundant is the *locust*, which always comes from the South, and often continues its visits for three, five, or seven years. When the swarms of these insects approach, they resemble an immense cloud darkening the sun; and when they settle on the ground to carry on their devastations, they are often crowded upon each other to the depth of several inches. They all advance in the same direction, climbing over every obstacle in their progress, clearing the ground of every vegetable substance, consuming even the bark of the trees, and announcing their approach at a considerable distance, by the noise of their feeding. In order to give a new direction to their course, the inhabitants are accustomed to dig pits and trenches across their path, which they fill with water, or with combustible materials, to

be set on fire at their approach; but so immense are the numbers of these destroyers, and so eagerly do they press forward their ranks, that the trenches are soon filled, and the flames completely extinguished by the constant succession of new swarms. A few gardens in the neighbourhood of towns are sometimes preserved from their voracity, by means of a palisade of reeds, inclining towards a ditch on the outside, so that the locusts, being unable to climb up this slippery and sloping bulwark, fall back into the trench, and devour one another. They partially disappear during the rainy season; and are frequently carried away by hurricanes into the sea. During those periods of desolation, the locusts are very generally used as food, and are even esteemed a great delicacy; but the lower classes of people, by living entirely upon them, are said to become very meagre and indolent; and, whether from this circumstance, or from the pestilential smell of the dead locusts, or from some other cause, the visits of these destructive insects are frequently followed by the plague. *Scorpions*, resembling a small lobster, about three inches in length, abound in stony places, and old ruins; and often infest the cities so much, that, in order to guard against their attacks, the inhabitants are accustomed to place the feet of their bedsteads in tubs or pans of water. The sting of the yellow coloured is the most venomous; and the flesh of the animal itself, applied to the wound, is the most effectual cure. Of the various kinds of *serpents* found in Barbary, two only are highly poisonous; namely the *buskah*, of a black colour, seven or eight feet long, with a small head, which expands to three or four times its usual size, when about to make its attack; and the *eleffah*, or *dipsas*, about two feet in length, and of the thickness of a man's arm, beautifully spotted with yellow and brown. The *boah*, or desert snake, an enormous monster, from twenty to eighty feet long, and thick as the body of a man, is not indeed of a venomous nature; but the velocity of its motion, which it is almost impossible to escape, and the greatness of its strength, which is able to crush the bones of an ox in its grasp, render it sufficiently formidable to the traveller. There are also *domestic serpents* in this country, some of which are to be found in almost every house, and whose presence is considered as a benediction upon the family.

It is not possible to form a correct estimate of the population of Barbary; but it has been conjectured, that it is not above one-fifth of what the country could support. The inhabitants are a very mixed race; and may be distributed into different classes; such as Turks, Moors, Arabs, Berebbers, Shellicks, Negroes, Jews.

Of these the least numerous are the Turks; but they are nevertheless to be considered as the sovereigns of North and East Barbary. They are in general a very abandoned race, the refuse of Turkey, chiefly composed of pirates and other banditti, who have either enlisted in the service of Algiers, Tunis, Tripoli, or who have fled from their country to escape the punishment of their crimes. "Yet these recruits," says Dr Shaw, "after they have been a little instructed by their fellow soldiers, and have got caps to their heads, shoes to their feet, and a pair of knives to their girdle, quickly begin to affect grandeur and majesty; expect to be saluted with the title of *effendi*, or *your grace*; and look upon the most considerable citizens as their slaves, and the consuls of the allied nations as their footmen." These Levant Turks generally intermarry with the native

Moors; and their descendants, called Cologliss, or Coloris, form a very numerous class, active, and intelligent, but extremely turbulent and ambitious.

The Moors, who may be considered as the descendants of those who were driven out of Spain, reside chiefly in the towns and villages. They have a sallow complexion, an aquiline nose, good teeth, black eyes, manly features, but frequently a very ferocious expression of countenance. Their limbs are clumsily shaped; their stature is commonly above the middle size; and their whole figure has rather a commanding appearance. They are naturally of a grave and pensive disposition, indolent to an extreme, and roused only by such violent passions as avarice and hatred. They have little curiosity or ambition after knowledge; and no spirit of enterprise, industry, or improvement. Their natural sagacity degenerates into duplicity, and they are guilty of the meanest acts of imposition; yet, with all their selfish cunning, they are often very improvident; and, with all their haughty appearances, they are capable of the most abject submission. They have been described by a very accurate observer, (who seems to have been sufficiently inclined to give as favourable a picture as possible), as ignorant and contemptuous of other nations, cruel and rapacious towards each other, living in continual suspicion and distrust, strangers to every social tie and affection, and scarcely susceptible of one tender impression; unparalleled in arrogance, insatiable in sensuality, and addicted to the most unnatural and degrading propensities. Some of the better educated among them, however, are courteous and affable in their manners, capable of much self-command in conversation, and slow in taking offence; but very noisy and implacable, when once they are irritated. They all possess one very noble trait of character in a most eminent degree, namely, fortitude under misfortune. Resigned in all things to the will of God, the Moor never despairs; no calamity or bodily suffering can make him complain; but he waits in patient hope for an amelioration of his condition. The character of this people, in short, is a very inconsistent combination of the savage and civilized state; and may be attributed, in a great degree, to the united influence of their education, government, and religion.

The Arabs of Barbary are partly the descendants of those, who at first over-ran the country, under their Mahommedan leaders, and who have still kept themselves distinct from the other inhabitants; and partly emigrants from Sahara, who advance into the more northern districts, whenever the depopulations of the plague, or other calamities, afford admission to a new colony. They are divided into an infinite number of tribes, which never mingle by intermarriages, and which are almost continually at war with each other. If united among themselves, they would be more than a match for any of the Barbary states, to which they are tributary; and in order to keep them more easily in subjection, it is the practice of these states to encourage mutual acts of hostility among their Arab subjects. They live in tents; and generally form their encampments at a considerable distance from any town or village. Their occupation consists in taking care of their flocks and herds, and in raising a little wheat or barley. When the land around their residence has become less productive, and their cattle have consumed all the pasture, they strike their tents, and remove to a more fertile spot. They are generally obliged to procure per-

mission, from the bashaw of the province, to settle in any particular place, in return for which indulgence they engage to pay a certain portion of their produce. The Arabs bear a great resemblance to the Moors, in their general character; but they are a more meagre, indigent race, frequently covered with rags and filth. Those among them, who live nearest the coast, are more hospitable and inoffensive; but it often requires blows to excite their respect, or to procure from them any accommodation. Those, again, who reside in the interior of the country, and especially on the borders of the desert, are lewd, cruel, and treacherous; habitual robbers, and cowardly assassins; who will indeed consider the person of a stranger as sacred, while he remains within their tent, but who will not scruple to murder their last night's guest, before he has well passed the bounds of their encampment.

The Brebes, or Berebbers, inhabit the mountains of North Atlas; and are supposed to be the offspring of the original inhabitants of Barbary, who retired thither upon the conquest of their country, and who have still in a great measure preserved their independence. They are of a fairer complexion than the Arabs, of an active and industrious disposition, of a robust and athletic frame of body. In the higher grounds, they dwell in caves; but, in the valleys, they occupy tents, or huts of earth. They seldom change their place of residence; and employ themselves in cultivating the soil, tending cattle, rearing bees, and pursuing wild beasts. They are very intrepid hunters, dexterous marksmen, and capable of enduring the greatest fatigue. They entertain a strong dislike of the Moors and Arabs, whom they regard as usurpers; and, as many of their tribes are extremely powerful, they pay or refuse tribute according to their own inclination. They have, indeed, gradually adopted the religion and customs of the Moors; but have still a distinct language of their own, which is supposed to be a dialect of the old Carthaginian. They are probably, however, a more ancient people in Africa, than either the Romans or Carthaginians; and, from the circumstance of their living in caves, it has been conjectured, that they may have formed a remote branch of the great nation of the Troglodytes. Mr Bruce describes a very savage and independent tribe called *Aardie* (perhaps the same whom Abbe Poirer terms *Audes*, and of whom he gives a similar description), residing near Jebel Aurez, and dwelling in huts of mud and straw. They occupy a very rugged and inaccessible tract of country; and the great hazard of attacking them was expressed by one of their Maraboots by the strong figure of "eating fire." They have a fair complexion, red hair, and blue eyes. They have the figure of a Greek cross marked with antimony on their foreheads; and affirm, that their ancestors were Christians. They seemed to rejoice more in that relation, than in any connection with the Moors; and Mr Bruce conceived them to be a remnant of the Vandals.

The Shelluhs inhabit the mountains of South Atlas, and are often confounded with the Berebbers; but they are ascertained to be a distinct race, and to speak a different language. They live generally in towns and villages, are chiefly employed in husbandry, and are very simple and peaceful in their manners. They are a very meagre people, and remarkably abstemious in their diet; subsisting almost entirely upon barley-bread and honey. Many families among them are supposed to be descend-

ed from the Portuguese, who formerly occupied many of the sea-ports of West Barbary.

Negroes are very numerous in Barbary, especially in the empire of Morocco, where about 30,000 of them were embodied as troops, in the year 1780, by the emperor Muley Ishmael. They are to be found also in every part of the country, and almost in every family, in the state of slaves. Their condition, however, in this respect, is very different from that of their countrymen who are transported to the West India islands; and they experience a treatment much more humane, than the general character of their Moorish masters would warrant us to expect. Sometimes, indeed, they are kept, like a stock of cattle, to propagate for the supply of the market; but in general they are regarded as members of the family into which they have been purchased; are carefully instructed in the principles of the Mahomedan faith; and usually obtain their freedom, after a servitude of eight or ten years. The more intelligent among them are taught to read and write; and, as soon as they are able to understand a chapter of the Koran, are immediately emancipated. These liberated negroes soon adopt the sentiments and manners of the natives; and many of the most able officers and industrious cultivators are of this class. They are in general better formed than the Moors, more lively and active, but if possible more capricious and blood-thirsty in their dispositions.

The Jews of Barbary, whose ancestors were expelled from Portugal and Spain, are diffused over the whole country; and are found even in the mountains of Atlas, exercising mechanical trades among the Berebbers. They are subjected to every conceivable species of oppression, and are frequently treated even more harshly than the beasts of burden. They are not permitted to possess lands, to wear a sword, to ride a horse, or to leave the country without special permission. They are obliged to wear such a habit, as may distinguish them at first sight; to address every Mussulman by the title of seedy or signor; and to pull off their sandals, whenever they approach any religious structure or consecrated place. They are no where more severely and more undeservedly oppressed; for the whole country may be said to depend upon their ingenuity and industry, and could scarcely subsist without their aid. They are the only good artificers, and have a share in all pecuniary and commercial transactions. They are employed even in coining the money of the different states, sometimes also in collecting the taxes; and seldom does a Moor attempt to carry on trade, without the assistance of a Jewish agent. They are tolerated in the observance of their religious worship; and, in towns, there is generally a particular quarter allotted for their residence, under the jurisdiction of an alcaide appointed by the government. They follow, in other respects, the customs of the Moors; and, under all their oppressions, they find abundant resources in their own superior sagacity and information.

The few Christians, who reside in Barbary, are temporary visitants for purposes of trade, the consuls of European states, the slaves of Moorish corsairs, the inhabitants of the Spanish settlements, and deserters from the Spanish garrisons. From a regard to their respective nations, they may sometimes experience the protection of the constituted authorities; but, by the Moors in general, they are held in as great contempt as

the Jews; and are exposed to every species of insult that bigotry and brutality can devise.

The renegadoes, or foreigners, who have adopted the religion of the country, may be considered as forming a distinct class among the inhabitants of Barbary. The greater part of them are Jews, who have sought, in apostacy, a refuge from their oppressions; others are fugitive criminals, or men of desperate fortunes, from Spain; and a few are the younger part of European crews, who have been shipwrecked on the coast. A renegado, upon his conversion, is circumcised, clothed in a Moorish habit, and conducted through the streets on horseback, accompanied with music and a great concourse of people. He then chooses a Mahommedan name, and fixes upon some person, who adopts him as a child, and who is afterwards called his father; but who is not considered as bound to take any farther notice of him. There may be a few instances of persons of this description having risen, by their abilities and knowledge, to situations of wealth and power; but, in general, their condition is exceedingly abject and despicable. The native Moors avoid their society, and seldom allow them to intermarry with their families. They are at liberty only to connect themselves with a negro, or the daughter of a renegado; and their descendants are not acknowledged as genuine Mahommedans till the fourth generation. They frequently find their situation so very deplorable, that they are ready to expose their lives to the greatest hazards, in order to make their escape from the country.

In all the states of Barbary, the government is of the most despotic description; and the inhabitants are subject to the most degrading oppressions. The supreme power is entirely without controul; and the lives and property of the natives are wholly at the disposal of their rulers. Every kind of cruelty and injustice is systematically practised; and it is even said to be a maxim of government in this unhappy country, that, "in order to rule the people effectually, there should always be a stream of blood flowing from the throne." The same principle of tyranny descends through the inferior classes of governors; and, provided they regularly remit to their superiors the required tribute, they are seldom called to account for their conduct. To be rich, is the greatest of all crimes in the eye of the Barbary princes; and such of their subjects, as have acquired property to any considerable amount, are very rarely permitted to enjoy it in peace. Their wealth is either openly extorted by the hand of power, or unjustly confiscated under the colour of law. The efforts of industry are thus completely paralysed; and the labours of the people are almost entirely confined to the supply of their immediate wants. Those who are affluent assume the appearance of indigence; and often, for still greater security, deposit their riches in the bosom of the earth. The secret of this concealment, if not extracted by torture, frequently dies with the possessor; and the amount of hidden treasures in Barbary is supposed to be much greater than the quantity of coin which is in actual circulation. According to the laws of the Koran, indeed, the forms of order and justice are generally observed, but very little of the substance exists; and, in most cases, judgment may easily be purchased by money. Trials are very expeditiously conducted; and the person accused is not always heard in his own defence.

Sentence is as expeditiously executed, as it is pronounced; and the condemned are not unfrequently hurried out of existence, without properly knowing for what offence they are made to suffer.

The punishments employed in this country are as severe as they are summary; and are continually varying, according to the fancy of the inhuman despots by whom they are inflicted. Less heinous offences are punished by imprisonment and the bastinado, by cutting off the hands or feet, by tossing in the air so as to bruise the criminal by the fall: There are persons, who have learned by practice to inflict the last mentioned punishment so dexterously, as to be able, according to their instructions, to dash out the offender's brains, to dislocate his neck, to fracture his leg or arm, or to make him reach the ground without sustaining any material injury. In the case of capital offences, there are many barbarous methods of inflicting death upon the wretched criminal. He is knocked down with clubs, stabbed, or beheaded with swords, and sometimes literally cut to pieces; thrown in a bag into the sea, impaled on a stake, burned alive, suspended from iron hooks, tossed upon sharp pointed pikes, dragged at the heels of a mule, and sometimes actually sawn asunder.

The religion of Barbary is the Mahommedan, of which it is unnecessary here to give a detailed account; but which, it may be observed, the Moors have greatly relaxed with respect to many of its precepts, and which, on the other hand, they have burdened with many additional superstitions. They secretly drink wine without scruple, and often to great excess; and easily satisfy their consciences by professing to take it as a medicine. In like manner, they render any prohibited food perfectly lawful, by merely ascribing to it some medicinal quality. They have the same ecclesiastical orders, acts of worship, festival seasons, &c. as other Mahommedans; but in addition to the public mosques, they have a great variety of private chapels consecrated to the devotion of individuals; and they surpass all the followers of Mahomet in the reverence which they testify to the different orders of saints. These are very numerous in Barbary, and of various descriptions; but they are known by the general name of Takeers or Marabouts,* and may be distributed into two principal classes. 1st, Those, who, by frequent ablutions, self-imposed austerities, strict observance of the Koran, and other acts of rigid devotion, have acquired the reputation of extraordinary piety. Of these, many are very sincere devotees, who make it their employment to visit the sick and to relieve the necessitous; but the greater part are artful hypocrites, who assume the appearance of sanctity, merely to promote their influence with the multitude. Those are particularly called Marabouts, who lead a retired life like hermits, pretending to possess magical skill, to foretell future events, and to be endowed with miraculous powers. These generally preside at religious ceremonies, marriages, funerals, &c.; and employ themselves in selling different kinds of amulets or talismans to their deluded votaries. Under this class may be ranked those itinerant mountaineers, who pretend to be great favourites with Mahomet, and to have power over all venomous reptiles; and who go about the country entertaining the people by eating snakes, vomiting fire, and other juggling tricks. They are sometimes known to run about in a frantic manner, leaping, dancing,

* Called *Marabouts* by Abbé Poiret, *Marabouts* by Lempriere, *Marabouts* by Shaw, and *Marabouts* by Jackson.

foaming at the mouth, and in these furious fits they often fall upon the first animal in their way, tear it to pieces with their teeth, and instantly devour it like beasts of prey; while the people are all the time anxiously soothing them with caresses, and using all possible means to quiet their frenzy.

2d, The second class comprehends all idiots and mad-men, who are considered by the Moors as under the special protection of heaven, and as moved by a divine impulse in every thing that they do. They are, therefore, treated with the highest veneration; carefully fed and clothed; and permitted, without restraint, to indulge in the most extravagant and immoral actions. Many of them are poor, imbecile, and inoffensive creatures, who find, in the superstition of their neighbours, all that humanity and protection which their helpless and degraded condition requires; but others among them are furious maniacs, who often amuse themselves in their malevolent fits, by tormenting and sometimes murdering such unfortunate persons as may happen to fall in their way; and not a few are the most depraved wretches in existence, who assume the character of insanity, that they may find an easy subsistence, and have full liberty to indulge in their brutal propensities.

This quality of saintship is considered as in a great degree hereditary, descending regularly from father to son, and sometimes even from master to servant. Every tribe and village almost has its tutelary saint, to whom the inhabitants regularly carry their first fruits, and pay similar acts of superstitious homage. They are frequently employed as guides to travellers, and their presence affords the best protection from every insult or aggression. They are not only venerated during their lives, but, after death, their tombs are generally held sacred; and chapels of an octagonal form are often erected on the spot, which are regarded as at once the most holy oratories, and the most inviolable asylums. The habitations of the living saints are generally near these tombs of their ancestors; and are often surrounded with importunate votaries, who, from touching the garments or receiving the benedictions of these consecrated personages, expect the remission of their sins, and success in all their undertakings. In these sanctuaries, prayers are offered up, as the last resort in desperate cases; treasures are deposited, as in the most secure of all concealments; and a refuge is found by the greatest offenders, which the most powerful are afraid to violate. Among the Moors, also, as among all other Mohammedans, those persons who have made the pilgrimage to Mecca, are held in the highest veneration; are considered as having received at once the remission of sin and an increase of perfection; are denominated *Hage*, that is, "holy;" and are always addressed by the title of *Seedy*, or "my lord." Even the camels and horses which have made this sacred journey, are counted *Hages*; are well fed, exempted from labour, and permitted to graze at full liberty wherever they may choose to stray. Hospitality and alms giving are the cardinal virtues, and the indispensable obligation of Mussulmen; but the Moors are more deficient in those duties than the Turks, and most other followers of Mahomet. Their standard of benevolence, indeed, is not very high; as no one is held bound to bestow alms who does not possess 5 camels, or 50 sheep, or 200 pieces of silver; and when they have given 6d. in the pound to the poor, they are considered as having yielded complete obedience to the precept.

VOL. III. PART I.

The state of knowledge in Barbary is low in the extreme; and the modern Moors have not the smallest portion of the literary spirit of their ancestors. They are not deficient in natural genius and abilities; but their minds are degraded by their oppressive government, and cramped by their limited education. In the state of childhood, they display an uncommon share of acuteness and vivacity; and are remarkable, while at school, for their memory and application, but after having been taught to repeat a few select passages from the Koran, and perhaps also to read and write, their progress in learning is terminated, and they are allowed to grow up without any farther discipline or instruction. There are still some remains of literary institutions in the city of Fez; and the children of the more wealthy Moors are sometimes sent thither to acquire a more accurate knowledge of the Arabic language, and to be instructed in the religion and laws of their country. Their studies, however, are confined to the Koran and its comments; or, at the utmost, to the cultivation of poetry, to which their language is admirably adapted. They generally record any extraordinary event in rhyme; and the young men sometimes hold extemporary poetical conversations, in which they display an astonishing fluency of expression, and accuracy of measure. One great trial of skill on these occasions, consists in proposing enigmas in verse, of which another person expresses the solution in corresponding measures. The rest of their literature is composed of a little inaccurate geography, and some tiresome memoirs of modern transactions among themselves. They have no conception of the speculative sciences, and wonder at the folly of Europeans, who bestow time and expense upon such pursuits. They are utterly ignorant of mathematics; and regard as unmeaning curiosities the few philosophical instruments of their ancestors, which have been preserved among them. Of the MSS. which they possess of the works of several learned Arabians, those only are considered as worthy of perusal, which treat of astrology and magic. The elementary operations in algebra and arithmetic are not understood by one in twenty thousand; but they display the greatest ingenuity and quickness of apprehension in making calculations by memory, and communicating the results, by touching each others fingers. Their most profound astronomers do not possess sufficient skill in trigonometry to construct a sundial. Their whole art of navigation consists in what is called pricking a chart, and distinguishing the principal points of the compass. Their highest attainment in chemistry is the distillation of rose-water. The extent of their physiology is to distinguish the figures of a few plants and animals in a Spanish edition of Dioscorides. The amount of their medical skill is to know the properties of a few simples, and to accompany the application of these with suitable incantations. They depend chiefly upon topical remedies, and seldom make use of internal medicines. They can scarcely even be brought to conceive how a substance, received into the stomach, should be able to reach the head or the extremities. A decoction of ground pine is frequently used in fevers, of arisarum in the stone, and of hanzæra in the venereal disease. The gall of the bird *houbury* is in great esteem as a cure for sore eyes; and a composition of myrrh, saffron, aloes, and myrtle berries, is given in the plague. A drachm or two of orbanche root is given in diarrhæas; and round birthwort is a sovereign remedy for colics and flatulen-

K k

ces; but the great resource in all distempers is the *hammanis* or natural hot baths and springs. Their surgery consists much in bleeding, cupping, scarifying, and fomentations. In rheumatism and pleurisy, they scarify, or puncture with red hot iron, the place that is affected. They sometimes evacuate the water, in hydrocele, with a lancet; and even couch for the cataract, with a piece of thick brass wire, terminating gradually at one end in a point not very sharp. Simple and gun shot wounds are healed by actual cautery, or by pouring fresh butter boiling hot into the sore; and the roasted leaves of the prickly pear are applied as warm as possible, to bruises, boils, and other inflamed swellings. The bite of venomous animals is cured by burning or cutting deep upon the wounded part; or by burying the patient to the neck in hot sand to produce perspiration; or, if no great danger is apprehended, by applying merely hot ashes, or the powder of alhenna, with two or three slices of onion, by way of cataplasm. They occasionally inoculate for the small-pox, upon the fleshy part of the hand between the thumb and forefinger; and in these cases they think it necessary to purchase the matter from an affected person, by giving a few nuts or comfits in exchange. The patient is kept warm; fresh butter is rubbed upon the skin to prevent pitting; 6 or 8 grains of alkermes are now and then administered to throw out the pustules; and the eye-lids are tinged with lead ore to prevent the ulcers from falling upon the eyes.

The mechanic arts, likewise, are in a very rude state among the Moors; and seem to have undergone no improvement whatever for many ages past. Their tools are very few and simple; their implements of husbandry, &c. especially their ploughs, mills, looms, forges, are all in miniature, and, at the same time, most clumsily constructed. A goldsmith, for instance, will come to work for his employer in the corner of a court, where he soon fixes his stall. His anvil, hammer, bellows, files, and melting ladles, are all brought along with him in a bag: His bellows are made of a goat skin, into which he inserts a reed; and holding this with one hand, he presses the bag with the other, and thus kindles and blows his fire. Other trades are carried on with the same rude simplicity; and yet, so ingenious are the workmen, that they can accomplish comparatively great things, by the most inadequate means. Their wants indeed are few, and easily supplied; and it is only the most useful and essential arts, that are generally practised among them. The art, with which they are most conversant, and in which they display most knowledge, is that of architecture. Their mode of building seems to have continued from the earliest ages, without the smallest alteration; and appears, upon the whole, to be well adapted to the climate. They are not capable, indeed, of producing any scientific plans, or elegant proportions; and the distinguishing character of their edifices is massy strength. But their cement is peculiarly excellent; and is very probably the same kind which has been employed in the most ancient fabrics. It is composed of one part of sand, two of wood ashes, and three of lime, which, after being well sifted and mixed together, is beaten with wooden mallets, three days and nights without intermission, and frequently sprinkled, during this operation, with a mixture of oil and water. For the purpose of connecting the earthen pipes of their aqueducts, they beat together only tow, lime and oil, without any water. Both these kinds of cement acquire, in a short time, the hardness

of stone; and are completely impenetrable by water. The walls of the cities and houses of Barbary are generally built of tabby or tabia, which may be called an artificial stone, and which seems to be a remnant of ancient Moorish art. It is a species of mortar, consisting of lime, sand, and small stones, put into wooden frames, (which are removed when the work is dry,) and beaten together with square rammers. The mosques, palaces, and other public edifices, indeed, are frequently faced with hewn stone, or marble; and some of these structures are of very great extent, comprehending a number of buildings, surrounded by a wall like a separate town. Their roofs are sometimes of a pyramidal form, and covered with green varnished tiles, which give them at a distance a very lively and agreeable appearance. In the towns and villages the streets are very narrow, seldom paved, never cleaned, and generally heaped with dust and filth. On each side there is frequently a row of shops, and behind these are the outer walls of the houses, which are, for the most part, of a rude construction, that the owners may not be suspected of being rich. The entrance into these habitations, from the street, has a very mean appearance; and the first apartment is very commonly a kind of stable, or, at least, a porch or gateway surrounded with benches for the reception of visitors. Through this vestibule is the passage into a square court, which has sometimes a fountain of water in the centre, and a porch, supported by pillars, along each of its four sides. This open space, in the houses of the opulent, is paved with marble, or with chequered tiling; and in sultry weather (especially when employed, as it often is, for receiving company) is covered by a sheet or veil, which is expanded upon ropes from one side of the parapet wall to the other. The houses are sometimes two, and even three stories high; and, in these cases, there are galleries for each flat, passing along the whole inside of the court, in the same manner as on the ground floor: But they seldom consist of more than one story, about 16 feet in height. Each side of the court generally forms one long, narrow apartment; and one of these rooms frequently serves a whole family, as a lodging. The entrance into these chambers is from the inner sides of the court, by means of large, folding doors, which are generally left half open to admit the light and air; and which are therefore furnished with hangings on the inside. These doors are ornamented with chequered pannels or carving; and are sometimes made altogether of stone, moving upon pivots, fitted to sockets in the lintel and the threshold. The ceilings of the apartments are generally of wainscot, neatly painted or studded with gilded mouldings; the upper part of the walls is adorned with fret-work or stucco figures; while the lower space nearest the floor is covered with hangings of coloured cloth, or of the skins of lions and tygers, suspended upon hooks, and thus easily taken down or put up at pleasure. But sometimes, instead of these curtains, the sides of the rooms are ornamented with looking-glasses of various sizes, or with watches and clocks in glass cases, or with a display of muskets and sabres fancifully arranged. There are no fire places in the apartments; and the victuals are prepared, in a corner of the court, in an earthen stone heated by charcoal. The floors are laid with painted tiles, or plaster, and covered with mats or carpets. Along the sides of the walls are ranged mattresses and bolsters, upon which the family sit during the day, and generally sleep during the

night. At the same time there is, also, at one end of the chamber a little gallery, raised above the floor to the height of three, four or five feet, in which the beds are frequently placed; and sometimes instead of these, an European mahogany bedstead may be seen in the houses of the wealthy, but this is intended rather for ornament than use. As the use of chairs and tables are unknown in this country, the remaining part of the furniture consists of a clock, a few arms, a tea equipage, and some china vessels. The Moorish houses are very dark and gloomy; as the windows are extremely small, and all look into the court, except perhaps one lattice or balcony, above the gateway towards the street, which however is very seldom opened, unless on festival days. The stairs are either in the porch, or in the corners of the court. The roofs are flat, covered with plaister, and surrounded with a parapet: There the female part of the family are accustomed to walk and amuse themselves in the cool of the evening. To the habitations of the more wealthy, an additional building is frequently attached, called the *Alee* or *Olah*; the apartments of which are used as wardrobes, as places of greater retirement, or as a lodging for strangers. The houses are generally whitened on the out side; and appear, at a distance, like vaulted tombs in a church-yard. The villages are always in the neighbourhood of the towns; and are composed of huts of stone, earth, and reeds, surrounded with thick and high hedges.

The encampments of the Arabs, which are generally at a distance from the cities, consist of a number of tents, from 3 to 300, and are called *Douars*.* Each of these is under the authority of a Sheik, (or Shaik,) who is appointed usually by the government in whose territories they reside, and who is commonly the man of most property in the tribe: The Berebbers, however, assert the privilege of choosing their own chiefs. The coverings of the Arab tents are made of a coarse thick stuff, of woollen, of camels and goats hair, or of palmetto leaves; and is always dyed of a black or brown colour. Their form is broad and low, about 8 or 10 feet in height, and between 20 or 25 in length, having the appearance, according to the description of Sallust, of an inverted boat: "*Edificia Numidarum, que mapalica illi vocant, oblonga incurvis lateribus tecta, quasi navium carina essent.*" They are divided into separate chambers by means of curtains; and one of these is always allotted for the calves, foals, and kids. Their furniture is exceedingly simple, consisting only of a little straw, a mat, or coarse carpet for bedding, a few earthen vessels for cooking, a wooden bason to draw water or hold milk, a goat skin to churn the butter, and two portable mill-stones to grind the corn. The poles, which support the roof of the tent, are furnished with a number of hooks or pins, upon which are suspended their clothes, baskets, saddles, arms, &c. These tents are generally arranged in the form of a crescent or circle, and sometimes of an oblong square. The flocks and herds are brought at night into the area; the entrance of the douar, and the vacant spaces between the tents, are then closed up with bushes and thorns, as a defence against beasts of prey: while there is in every encampment an additional guard of ferocious dogs, which bark with great fury at the approach of strangers. In the

centre of the douar there is generally a large empty tent, which serves the purpose of a mosque, a school-house, and a lodging for the traveller. The Berebbers have habitations very similar to those of the Arabs; but, instead of tents, they frequently construct huts of wicker work, daubed over with mud; and a collection of these is called a *Dashkra*.

The inhabitants of Barbary are remarkably abstemious in their diet; and can subsist upon a very small quantity of the simplest nourishment. The lower classes, especially among the Arabs, live chiefly upon the roots of vegetables, wild fruits, and a mixture of meal and water; a few balls of which, or a few dates, and a draught of camel's milk, will often support them, on a journey, for a whole day. The principal dish among all ranks, from the prince to the peasant, is cuscusoe,† a kind of granulated paste made of flour very coarsely ground, heaped up in a vessel full of small holes, placed above the pot, in which the vegetables or flesh meat is boiled, and in this manner stewed by the rising vapour: It is then mixed with soup, milk, butter, honey, spices, pot-herbs, or animal food. The more opulent persons have various preparations of almonds, dates, sweet-meats, milk, honey, and other delicacies; and all ranks in Barbary use a great proportion of bread, of which they often make a meal, with the addition of a little oil, vinegar, or milk. The Moors, agreeably to the Jewish custom, cut the throats of all the animals which they use for food, at the same time turning their heads towards Mecca in adoration of their prophet; and, after suffering them to bleed freely, they carefully wash away the remaining blood, and divide the meat into small pieces about 2 lbs. in weight. The natives of Barbary are very regular with respect to their hours of eating. They breakfast soon after day-break; take a slight repast about noon; and make their principal meal at sunset. At these seasons, a large, flat earthen dish, full of the prepared food, is placed upon a low, round tray, or merely set upon the floor. Around this the family seat themselves, cross-legged, upon mats; and, having previously washed their hands, they tear the meat with their fingers, and form it along with the cuscusoe into little balls, which they throw with a dexterous jerk into their mouths. They make no use of knives and forks, and very rarely even of spoons. The male part of the family eat in one company; the females in another; and the children, with the servants, in the third. But among the Arabs and Berebbers the master of the tent generally eats alone; the dish then passes to the children; next, to the wives; and, lastly, to the domestics. After eating they again wash their hands, mouth, and beard; but sometimes content themselves with wiping their fingers on their clothes, or in the woolly heads of their negro slaves. It must be observed also, that, before beginning a repast, and even before entering upon any kind of work, they reverently utter the word *Bismillah*, that is, "in the name of God;" and upon concluding their meals, or completing any undertaking, they say, in like manner, *Alhandillah*, that is, "God be praised."

One of the greatest luxuries among the Moors is tea, which they greatly prefer to coffee; but, as it is a very scarce and expensive article in Barbary, it is used only

* *Dou-wars*, according to Shaw; *douares*, according to Abbé Poirét; *douhars*, according to Lempriere and Chemer; and *dour*, according to Jackson.

† *Cuscasowe*, according to Shaw; *couscousou*, according to Abbé Poirét; *cuscousou*, according to Lempriere; *cooscasoo*, according to Chemier; and *cuscusoe*, according to Jackson.

in the houses of the rich. In order to prepare it for use, they put some green tea, a little tansy, the same quantity of mint, and a large proportion of sugar, into the pot, at the same time; and then fill it up with boiling water. After it has been infused a proper length of time, it is poured out into very small china cups, and taken without milk. Of this refreshing beverage, they drink very great quantities, whenever it is introduced, and continue slowly sipping it with great relish, for the space of two hours together. Besides using snuff, they take much pleasure in smoking tobacco; and, for this purpose, they use a wooden tube about four feet in length with an earthen bowl. They often mix with the tobacco the cut leaves of the *hashisha*, or African hemp plant, which produces a kind of sensual stupor, and excites agreeable dreams. The *kief*, which is the flower and seed of the *hashisha*, is still more powerful in its effects; and about one common English tobacco pipe-full is sufficient to produce complete intoxication. This they prefer to opium, wine, or brandy; and so great is the infatuation of those who use it, that they cannot exist without its exhilarating or rather stupifying influence. They have several other plants of a similar quality; among which the nuts of the palma christi hold a principal place, and have the remarkable effect of intoxicating a person for the space of three or four hours, in such a manner, that he completely opens his mind, and utters all his thoughts.

The Moors have in general rather a superabundance of clothing, which very much conceals the form of their persons; but the fashion of their dress is supposed to be very ancient, and bears a great resemblance to that of the patriarchs, as represented in paintings. That of the men consists of a red cap, or turban, and frequently of both, the latter being wrapped round the bottom of the former, and serving often to distinguish the rank or profession of the wearer, by the number and fashion of its folds; a pair of linen drawers, reaching to the ankle, over which they sometimes wear another pair of woollen cloth; a linen, cotton, or gauze shirt, generally hanging over the drawers, with large and loose sleeves; a vest, or tunic, called a *caftan*, resembling an European great-coat, generally made of cotton in summer, and of woollen in winter, sometimes with and sometimes without sleeves, connected before with very small buttons down to the bottom, and fastened tight around the body with a sash; a sash or girdle of worsted, fine linen, cotton, and sometimes of silk, in which are frequently stuck a knife or dagger, and one end of which is sewed up to serve as a purse; a velvet cord, crossing over the right shoulder, and suspending a sabre on the left side; yellow slippers on their feet, instead of shoes, but no stockings on their legs. This is their usual dress, when in the house, or when employed in any kind of work; but, when they go abroad, they throw over all, in a careless but elegant manner, a garment of white cotton, silk, or wool, called a *hayk*,* five or six yards in length, and about two in breadth, very similar to the Scotch plaid, and supposed to be the same as the *ficulus* of the ancients. Instead of this, and frequently above it, they use occasionally a blue cloak with a hood, called a *burnose*, made of woollen cloth, and of a very close texture, so as to resist the rain. The Moors wear their beards long, but have their heads shaved, except a single lock in the middle. The more wealthy have plain gold rings

upon their fingers; and frequently carry a rosary in their hands, more by way of ornament, than for any religious purpose. The Arabs wear no linen, and, except in paying visits, (when they always put on drawers) have seldom any other garment than the *hayk*, which serves them at once as a covering through the day, and a bed during night. They fasten the two upper corners before the breast, and over one of the shoulders, with a wooden bodkin; and then wrap the rest of the robe about their bodies, while the outer fold is generally employed to hold such articles as they may have occasion to carry. Their heads are almost always without any covering, except a narrow fillet around the temples to bind up their hair, or the hood of the *burnose* drawn up during a shower. On the confines of Sahara, they are often completely naked, or, at most, have only a pair of thin drawers. The Berebbers wear the drawers and the *burnose*. The dress of the Jews differs very little from that of the Moors, except that their cap, slippers, and outer garments, must always be of a black colour. Lepers are obliged to distinguish themselves, by wearing a straw hat, with a very broad brim, tied on in a peculiar manner. The natives of Barbary are scrupulously cleanly with regard to the insides of their houses; and cannot endure the slightest contamination to remain near the place where they sit. The frequent ablutions, also, imposed by their religion, (though often performed in a very slovenly manner,) tend to give them a great appearance of personal cleanliness; but their garments are very seldom washed, and are generally in a very disgusting state of filth.

The condition of the women in Barbary is the same as in other Mahomedan countries. Reared in ignorance, and imprisoned in their apartments, they are rather the slaves than the companions of their husbands. Those, who reside in towns, seldom leave their houses, except for the purpose of visiting one another; and, when they do go abroad, they are so completely veiled, that they cannot be distinguished by their nearest relations. On these occasions, women of rank always ride on mules, or in litters, attended by a slave; and it is only the servants, the aged, and the very lowest of the people, who are seen walking in the streets. Among the Arabs, and the inhabitants of the villages, the women have more liberty; but they have also more labour. They are continually occupied in weaving at the loom, grinding corn with the hand-mill, cooking the provisions, attending the cattle, and after a day of fatigue have to trudge, often two or three miles, perhaps with their infants on their backs, to bring water. They are generally required also to equip the horses, to take down and pack up the tents, and sometimes to carry heavy burdens on foot, while the lazy Arab is riding at his ease. They are subjected in short to every species of drudgery; and it is even affirmed, that, in some parts of the country, they are occasionally yoked with the cattle in the labours of the field. The women of this country are generally handsome, and have a great degree of rustic simplicity in their manners. Their persons are rather below the middle stature, remarkably fat and square, with large hands and feet. Their faces are round; their nose and mouth small; and their countenances, though beautiful, very deficient in expression. They have, however, a very noble gait, a complexion as fair as the females of Europe, and, ex-

* *Hyle*, according to Shaw; *halik*, according to Lempriere; *haïque*, according to Chénier; *hayk*, according to Jackson.

cept when descended from renegadoes, their eyes and hair are universally black. In the inland districts, especially towards the south-west, and in some particular cities, such as Rabal and Mequinez, they are said to be exquisitely beautiful. The lower classes, indeed, and especially the Arab women, who are seldom veiled, have a very swarthy complexion, and are rarely well-favoured. Those who are generally seen in the streets, are round shapeless bundles, resembling bales of cloth in motion. Covered to the mouth with woollen, and staring through a dirty rag hanging over their face, they have altogether a very hideous and disgusting appearance. Copulency is considered as their principal charm; and the fattening of young women thus becomes a very important object of domestic attention. In order to promote this growth of beauty, they use in their food a powder called *elhoub*; and swallow great quantities of paste heated in the steam of boiling water. But their sedentary manner of life contributes perhaps more effectually, than all other means, to produce that plump habit of body, for which they are distinguished. Their dress consists of drawers, shirt, and tunic, nearly resembling those of the men; except that the neck of the two latter is left open, and the edges generally ornamented with embroidery. To their girdles of silk, or crimson velvet, are attached two broad straps, which pass under each arm over the shoulders, forming a cross upon the breast, and suspending a gold chain in the front. The hair, which it is their great pride to have very long, is plaited backwards from the forehead, in a variety of folds, hanging loose behind, but fastened together at the bottom by a little twisted silk. A long narrow stripe of gauze or silk is then wrapped round the hair in such a manner, that the ends intermingle with the tresses, and hang down behind almost to the ground. A handkerchief of linen, crape, or common silk, surrounding the head like a close cap, and collected in a bow behind, covers and completes the head dress. At the upper part of the ears, they have a small gold ring with a cluster of precious stones; and at the lower part, another ring and cluster of a larger size. They wear also rings on their fingers, bracelets on their wrists, rims of gold or silver on their ankles, and a variety of necklaces, composed of beads, pearls, or gold chains. They sometimes use a kind of loose stocking to give the leg a thicker appearance; and wear slippers, always of a red colour, and generally embroidered with gold, which they take off, when they enter their apartments. Besides the veil and hayk, with which they cover their heads, when they walk out, they sometimes wear also straw hats, with a view to keep off the rays of the sun. The dress of the lower classes consists chiefly of drawers, and a coarse woollen tunic tied round the waist by a band, with a common handkerchief upon their heads; but frequently in the house, and especially in the tents, they have no other covering than a towel around their loins. At all times, however, and in the midst of all their drudgery, the lowest and most wretched among them are loaded with all the trinkets which they possess, such as ear-rings, bracelets, necklaces, and even small looking-glasses hanging on their breasts: This may be partly owing, indeed, to their having no proper place in which to deposit them. The women of the Jews are the most handsome, and the most inclined to intrigue. Those of them who are married, are not required to wear veils; and are permitted to walk about, without much restraint. Their

dress is similar to that of the other Barbary females, except, that instead of drawers, they generally wear petticoats of green woollen cloth, with embroidered borders. All classes of women in Barbary are addicted to the use of various paints or cosmetics, to which may, in a great measure, be ascribed that shrivelled and aged appearance which their faces acquire at a very early period of life. They stain the corners of their eyes, their eye-lids, and eye-brows, with a black pigment, a preparation of lead ore; and it is accounted a great addition to their charms to have a long black stripe across the forehead, along the ridge of the nose, on the cheeks, and from the chin down to the throat. They paint their cheeks and chin, the nails of their fingers and toes, and the inside of their hands and feet, with a deep red. They frequently also tinge the whole of their hair, hands, and feet, with a herb called *henna*, which produces a deep saffron, or bright orange colour; and which imparts a pleasing softness and coolness to the skin. Most of the women among the Arabs and Berebbers imprint, with needles and gun-powder, the forms of flowers and other objects, on their face, neck, and other parts of their bodies. The women of this country very soon attain the state of puberty; are frequently mothers at eleven or twelve years of age, and grandmothers at twenty-two or twenty-three; and, as they live as long as Europeans, they generally witness several generations of their posterity. They lose their bloom, however, and cease from child-bearing about the age of thirty. They suffer very little inconvenience at the birth of their children; and are frequently on foot the next day, going through the duties of the house, with the new-born infant on their back.

The natives of Barbary marry at a very early age; and generally without having had much opportunity to establish an attachment of affection. In forming matrimonial connections, the parents of the parties may be said to be the only agents; and it frequently happens, that the bride and bridegroom do not see each other till the ceremony be performed. It is from their mothers or confidential servants that they learn the personal accomplishments and character of their intended helpmates. In most cases, however, the young man procures some opportunity of seeing his mistress at a window, or in some such distant manner; and should the interview prove mutually agreeable, he then proposes his wishes to the father. Should his offer be admitted, he sends presents to the lady, according to his circumstances; and if these be accepted, the parties are considered as betrothed. It is not expected that the bride should bring a portion along with her; but, on the contrary, the husband often pays to her parents a species of purchase-money: He specifies, at least, a certain sum to be given to her, should she happen to survive him, or to be divorced. If the father, however, possess much wealth, he generally presents his daughter with a supply of ornaments, and also allots her a suitable dowry; but all this is considered as her own property, and must be faithfully restored in the event of a separation. These arrangements are all made in the presence of the *cadi* by the friends of the parties; and this public transaction constitutes the marriage-contract. During several days before marriage, the bride remains at home to receive the congratulations of her friends, to be instructed by the *tabi*, or priest, in the duties of the married state, and to undergo the process of a fresh painting. During this period, the bridegroom receives the visits of his friends in the mornings; and in the evenings is paraded

through the streets on horseback, attended by a musical band of hautboys, drums, triangles, &c.; and surrounded by his male relations and acquaintances, who testify their joy, on these occasions, by dancing and jumping, and twirling their muskets in the air, by exhibiting their horsemanship, and by firing in the face and at the feet of the bridegroom. On the day of the marriage, the bride is placed in a square vehicle, about twelve feet in circumference, covered with white linen, or variegated silk, and fixed on the back of a mule. In this litter, she is carried through the town in the midst of her relatives and companions, accompanied with the light of torches, the sound of musical instruments, and frequent volleys of musketry. In this manner she is conducted to the house of her intended husband, who returns, about the same time, from a similar exhibition; and great care is taken, that she do not touch the threshold of the door as she enters. She then sits down, with her hands over her eyes, and the company retires; the bridegroom is introduced to her alone, perhaps for the first time; takes off her veil, and receives her as his wife, without any farther ceremony: Sometimes, indeed, especially among the Algerines, it is customary for the parties to plight their faith, by drinking out of each others hands. After the marriage, the friends are entertained with feasting and amusements, a greater or a smaller number of days, according to the wealth of the parties; and it is considered as incumbent on the man to remain at home eight days, and the woman eight months after their union. The husband has power to divorce his wife on various accounts, such as barrenness, unchastity, &c.; and the wife possesses a similar power, if her husband should fail to provide her with sufficient subsistence, or should three times utter curses against her. In Barbary, as in other Mahomedan countries, four wives are allowed to one husband; and as many concubines as he may choose to support. The Moors, however, seldom avail themselves of this indulgence; and, in a population of 100,000 souls, scarcely 100 men will be found, who possess the number allowed by the law. Even among the Bashaws, and other great men, the number of their wives increases only by degrees; and an additional one is seldom taken, till the former have lost their bloom. The first married, however, especially if she have born a son, is always regarded as the mistress of the house; and the younger wives are taught to pay her all due respect. The concubines are generally black women, who reside in the house along with the wives, and perform the menial offices of the family. The children of the wives have all an equal share of the effects of their father and mother; but those of the concubines can claim only half the proportion of the others. The marriages of the Arabs are conducted in a manner very similar to what has now been described; but are often celebrated with much greater show, and by much larger companies. The friends of the parties provide them with a tent and its simple furniture; and each brings to the joint stock a proportion of cattle and of grain. Though they generally wear nothing but woollen clothing, yet it is a custom, in many tribes, that the bridegroom and bride shall have each a linen shirt at their nuptials; but this they must neither wash nor put off, as long as it will hang together.

The Moors are equal by birth, and know no difference of rank, except what is derived from official employments; and even this is not retained, after these offices

are resigned. The exercise of the mechanical trades is never considered as, in the smallest degree, disreputable; and the governor or judge of a town would never think himself degraded by giving his daughter in marriage to a common artificer: The meanest man in the nation may thus aspire to a matrimonial connection with the most opulent. Persons bearing the name of Mahomed, which is generally given to the first male child born in wedlock, are always addressed by the title of Seedy, synonymous to Signor.

The usual mode of salutation in Barbary is, to put the right hand on the breast, to make a gentle inclination of the head, and in this posture to give the salem aliok, or the wish of peace. If the parties are intimately acquainted, they shake hands with a very quick motion; or merely make the extremities of their fingers meet, and then each puts his own to his lips; or mutually embrace, kissing the forehead, shoulders, or beard. They then inquire after the health of the relatives in due order; and, among the Arabs, on these occasions, the mare, flock, and even the tent, are not forgotten; but while putting these questions, they seldom wait for a reply, and are often far beyond each others hearing, before they have finished their civil interrogatories. When they meet a superior, they make the hayk, which is usually thrown loosely over the head, fall back upon the shoulders; generally pull off their slippers as they approach, and respectfully kiss his hand, or merely that part of his hayk which covers his arm, or sometimes even his feet. The superior, in these cases, presents the back of his hand for salutation; and it is accounted an indication of great favour, when he offers the palm. The compliment due to a sovereign, and to any of his family, is to uncover the head, and then to prostrate, or rather bend the body to the ground. It is common in Barbary to address a peculiar salutation to a person who is eating, drinking, smoking, sneezing, or belching; namely, *saha*, "may it do you good."

When the inhabitants of Barbary pay visits to each other, they generally ride on mules, rather than horses; and pride themselves greatly upon being attended, on these occasions, by several running footmen. They are not always received into the house; but, if the weather be fine, a mat or carpet is spread before the door; and upon this they place themselves in a circle, cross-legged, or resting upon their heels, while their attendants are seated in a similar manner. The streets are sometimes crowded with these parties, engaged in smoking, in drinking tea, in conversation, or in gaming. If the company be large, and an entertainment be given, the inner-court is frequently the place of meeting; and, on these occasions, a kind of veil or curtain is generally extended from the parapet walls, to shelter them from the heat or inclemency of the weather. The master of the house, when receiving his guests, remains upon his seat, takes their hand as they advance, inquires after their health, and directs them to their place. Whatever be the time of the day, tea is introduced, during the visit, in the houses of the opulent; and is accounted the greatest civility that can be shewn to the company. When a stranger arrives to lodge in the family, the first compliment offered is water to wash his feet, (which the circumstance of walking barefoot, or at most in loose slippers, renders a very necessary and acceptable ceremony;) and, in such cases, the master of the house is always the most active in doing the most menial offices to his guest.

The common topics of conversation among these people are, the occurrences of the neighbourhood, with respect to which, they testify the most eager curiosity; their religious tenets, which the talbs, or men of letters embrace every opportunity of introducing, in order to display their own acquirements; their women, on which subject their discourse is exceedingly low, trifling, and indecent; and, lastly, their horses, upon which it is accounted the greatest of all accomplishments to be able to harangue. In conversation, the gestures of the Moors are lively, graceful, and expressive; their accent peculiarly strong and sharp; and their voice remarkably full and sonorous. When they become hot and quarrelsome, they indulge in the most opprobrious language, and perhaps collar each other in their rage, but very seldom come to blows; though it sometimes happens, that a dispute is finally terminated by assassination.

The natives of Barbary are indolent to a very astonishing degree, unless when accidentally roused to some sudden fit of exertion; and hence their amusements are always in extremes, either of the most sedentary, or of the most violent description. They may often be seen in considerable numbers sitting on their hams, leaning against a wall, in complete apathy and silence, smoking their pipes, stroking their beards, or repeating their prayers with a rosary in their hands, or conversing together with the utmost vehemence. They are so extremely averse from standing or walking, that, if two or three should chance to meet, they instantly squat themselves down on the first clean spot which they can find, though the interview may not be intended to last above a few minutes. They spend great part of their time in the barbers' shops, which are the chief places of concourse, and the great sources of all intelligence; or in the coffee-houses, drinking tea and coffee, or playing at a kind of chess, in which they are very expert; but all games of hazard are strictly prohibited by their law, and they seldom play for money in any case. Tribes of wandering historians, or romancers, often amuse the vulgar by their wonderful relations; and dancers and jugglers by their tricks and agility. The young men, and especially the soldiery, often make merry with their concubines, with wine and music, in the taverns, or in the fields. The natives of this country are, in general, greatly delighted with music; and their quick tunes are very beautiful and simple; but their slow airs have a tiresome, melancholy sameness. Their principal instruments are the hautboy, the mandoline, (a Spanish instrument), a violin with two strings, the drum, the common pipe and tabor. Their more active diversions are, leap-frog, jumping, wrestling, and particularly foot-ball; in which last exercise, they do not attempt to send the ball to a goal, but amuse themselves by kicking it up in the air, without any definite object. Another favourite amusement, or rather military exercise, in which they continue for several hours at a time, is what they call the game of gun-powder; which consists in one party of horsemen riding full gallop against another, or merely towards a wall, suddenly stopping short, discharging their muskets, and retiring to resume the onset. Those are considered as the most expert in this amusement, who advance nearest the wall, and who stop short most instantaneously. This is their mode of engaging in battle, and also of complimenting a stranger. They load their pieces with loose powder; ride up violently to the persons, whom they mean to salute; and then suddenly checking their horses, dis-

charge their muskets full in the face of the honoured individual.

The care and management of their horse is their greatest pleasure and accomplishment; and it must be admitted that they excel in horsemanship. Their mode of training and riding, however, is very cruel and pernicious to these noble animals. They break them in when very young, by making them perform long and fatiguing journies, over a mountainous and rocky surface. They then teach them to rear up, to stand fire, to go at full speed, and to stop short, as has been described. Their horses, of consequence, have no other pace than a walk or gallop; and, by being broken in so early, and treated so barbarously, they are very soon rendered unfit for service. Their bridles have only one rein of very great length, which serves also the purpose of a whip; and the bit is so constructed, that, by a very slight pressure on the horse's tongue and lower jaw, it fills his mouth with blood; and, if not used with the utmost caution, would be so powerful in its check, as to throw him completely on his back. Their saddles are in some degree similar to the Spanish; but the pommel is still higher peaked, rising in a perpendicular direction, while the back part is elevated in such a manner, as to support the rider as high as the loins. They are covered with red woollen cloth, or even with red satin; and are fastened upon the horse by one girth round the body, and another across his shoulders. The stirrups are hung very short; formed so as to cover the foot, like a slipper; and placed far back, so as to give the rider a firmer seat, by inducing him to grasp the horse's sides with his knees. The spur is a spike, about six inches in length, hung loosely at the heel of the stirrup, a very barbarous looking weapon, which appears to a stranger ready to rip up the sides of the animal, but which a skilful rider keeps always between four or eight inches from the horse's belly, and seldom uses it so as to do him any injury.

Among the amusements of the Moors may be mentioned the sports of the field, such as hawking, which is much practised in the kingdom of Tunis, where there is a great variety of falcons; and fowling, in which the sportsman makes no use of dogs, but conceals himself under an oblong frame of canvass, painted like a leopard, in which are two or three holes, that he may perceive what passes, and may push out his musket when he is sufficiently near to the birds. They often take part-ridges by tunnelling, or inclosing them in a net by means of a decoy bird in a cage; and sometimes by springing the coverts repeatedly, till the birds become fatigued, when they take them with dogs, or knock them down with sticks. A whole district is often assembled to hunt the lion and leopard. The company encompass a space of three or four miles in circumference, gradually contracting their circle as they proceed; the footmen with dogs and spears advancing in the front, while the horsemen are a little behind, ready to charge upon the first sally of the wild beast. Sometimes they form traps for these animals by digging holes in the ground, formed like an inverted cone, and slightly covered with earth. At other times, the Shellubs and Berebbers take their stations, near the resort of these destructive animals, sometimes on the top of a tree, and sometimes in small round towers built for the purpose, with a hole or two in the wall for a musket; and will patiently remain in these places for whole days, living on barley meal and water. Their manner of hunting the hyæna is also

very singular, and deserves to be particularly mentioned. Ten or twelve persons repair to the cave, which the animal is understood to frequent, and in which he always remains through the day. One of these strips himself naked, seizes a dagger in one hand, and taking the end of a rope with a noose in the other, he advances gradually into the cave, speaking gently, with an insinuating tone of voice, as if with a view to fascinate the hyæna. When he has reached the animal, he strokes his back in order to soothe him, dexterously slips the noose round his neck, throws a piece of cloth over his face, pulls the rope at the same instant to indicate to his companions that it is fixed; and then, retiring behind, urges the animal forward, while the dogs attack him in front, as he is dragged along. In the pursuit of the ostrich, the Arabs make use of the desert horse, and set out in a party of twenty or more, riding gently against the wind, one after the other, at the distance of about half a mile asunder, till they discover the foot marks of the bird. When they come in sight of their game, they rush forwards at full speed, always observing the same relative distance. The ostrich, finding her wings an impediment to her progress when thus moving against the wind, turns towards her pursuers, endeavouring to pass them; and though she may escape the first or second, she is generally brought down by the musket or bludgeon of those that follow.

The natives of Barbary are subject to many loathsome and distressing diseases, which are greatly aggravated by their extreme deficiency in medical knowledge. The most prevailing distempers are, the falling sickness, which is generally confined to women and children; a temporary headache, which arises from sudden stoppage of perspiration, and is chiefly removed by using exercise; inflammation of the eyes, frequently terminating in total blindness, and arising probably from the strong reflection of the sun's rays by the whitened houses; complaints of the stomach, proceeding from bile, indigestion, and the bad quality of their water; chronic rheumatisms, white swellings, and dropsies, which last disorder may be owing in a great measure to their poor living; hydrocele, which is extremely common among the Moors, in consequence of their warm climate, their loose dress, their licentious indulgences, and their immoderate use of the warm bath; the itch, which seems to be occasioned by their constant use of stimulants, and which frequently breaks out into very bad ulcers; leprous affections, which are generally hereditary, and which are very seldom completely cured; the venereal disease, brought by the Jews from Spain, is exceedingly prevalent among the Africans, and for which they have no radical remedy, but from which they experience less suffering than Europeans, owing to the constant perspiration, which the heat of the climate supports, their great use of vegetable diet, and their abstinence from spirituous and fermented liquors; and, lastly, the plague, which generally visits the country once in every twenty years, and which is always peculiarly destructive.

When any one dies, a number of women are hired for the purpose of lamentation; and they perform their duty by making the most frightful howlings, by beating their heads and breasts, and tearing their faces with the nails of their fingers. They are so expert in the expressions of grief, that they seldom fail, by their mournful sounds and afflicted gestures, to impress the funeral assembly with the deepest thoughtfulness and sorrow. The dead

are interred a few hours after their decease; and the greatest importance is attached to the rites of burial. It is an opinion among the Moors, as it was among the ancient heathen, that the souls of those, who have not received proper interment, are excluded from the abodes of the blessed; and hence, it is accounted the most dreadful of all punishments to be cut to pieces and thrown to the dogs. As soon as the dying person has breathed his last, the body is carefully washed, and sewed up in a winding sheet of white cloth: For this purpose, cloth, that has been brought from Mecca, and blessed by the Inam of that city, is most highly valued. The corpse is next placed on a bier, and carried on horseback, or men's shoulders, to the burying ground; which is always on the outside of the town, and of which every family has a portion walled in for their own use. All devout persons account it a highly meritorious duty to assist in these rites; and to accompany, at least a part of the way, every dead body which they may happen to meet. The attendants walk two abreast, go very quick, and sing hymns adapted to the occasion. The grave is made wide at the bottom and narrow at the top; and the body is deposited on its side, with the face towards the east, and the right hand under the head, pointing towards Mecca, while one of the priests generally puts into the hand a letter of recommendation to Mahomed. An arch is, in most cases, formed over the body with branches of trees to keep off the earth; different kinds of vessels and utensils are frequently interred along with the corpse; large stones are placed upon the grave to resist the attempts of wild beasts; and a flag is finally erected over the spot. It is customary for the female relatives to weep at the tombs of their deceased friends for several days after the funeral; and all, who pass by a burying ground, offer up prayers for the dead. When a woman loses her husband by death, she mourns four months and eight days, during which period she wears no silver or gold; and, if she happen to be pregnant, she must continue mourning till her delivery, while the relations of her late husband are bound, in the mean time, to provide for her subsistence. The men usually express their grief by abstaining from shaving their head, from trimming their beard, and from paring their nails.

The manufactures of Barbary are chiefly such as are requisite for the supply of the inhabitants; and are seldom prepared for exportation. The principal articles, produced in the country, are, the burnose and hayk of white wool and cotton, or cotton and silk, made almost entirely by the women, and woven with their fingers without the aid of a shuttle; silk handkerchiefs, which are manufactured chiefly in the city of Fez; various kinds of silk stuffs, frequently chequered with cotton; red caps, most of which are made at Tetuan; a coarse linen stuff, of which the best is produced in Susa; carpeting, nearly equal to that of Turkey; beautiful matting made of the leaves of the palmetto, or wild palm-tree; paper of a very inferior quality; muskets and sabres of Biscay iron, well tempered by means of certain waters in the country well adapted for that purpose; gun-powder of a very glutinous nature, exceedingly apt to imbibe humidity, and so deficient in strength and inflammability, that one ounce of European manufacture is equal to three or four of the Barbary article; but a certain Arab tribe, named Wolled Abbusebah, are said to possess the secret of making a species of gun-powder superior to any other in the world: leather, made

of goat skin, the mode of tanning which they are very careful to conceal, and the softest and finest of which resembling silk, and impervious to water, is prepared at Taflet. The manufactures of Algiers and Tunis are brought to a state of greater perfection, than those of Morocco; and the inhabitants of the northern districts are a more enterprising and commercial people, than those of the south. The Moors are utterly unacquainted with the art of casting cannon, the manufacture of glass, the invention of pumps, and the use of wheel carriages. They take no care to make or repair public roads, and have very few bridges. Hence their inland traffic is extremely limited; and is confined almost entirely to their markets or fairs, which are held in different districts for the accommodation of the neighbouring inhabitants. At these fairs they assemble, from a considerable distance, to buy and sell cattle, corn, vegetables, dried fruits, carpets, hayks, and the various productions of their country; and in one quarter of the market-place are to be found always a number of itinerant barbers or surgeons, to whom the diseased are brought for cure; while there is generally a guard of soldiers sent by the governor of the province, or of the nearest town, to prevent those bloody quarrels, which not unfrequently take place at these resorts, between the different Arab tribes. All the states of Barbary indeed, by means of caravans, carry on a very lucrative and extensive commerce with Mecca, the most consecrated seat of their religious faith; and with Tombuctoo, the great emporium of central Africa. For the expedition to Mecca, several thousands of camels, horses, and mules are collected, carrying merchandise to the value of two millions of dollars. Besides woollen stuffs, leather, indigo, cochineal, ostrich feathers, the traders never fail to take with them, or to purchase by the way, such articles of commerce, as can be sold with profit, at Alexandria, Cairo, and the other towns, through which they pass. These companies of merchants and pilgrims (for the two characters are generally united in this journey to Mecca), bring back with them Levant and Persian silks and muslins, amber, musk, essence of roses, &c. The caravans, which penetrate the interior of Africa, are neither so numerous nor so valuable as those which go to Mecca. They travel through the desert of Sahara, occupying several months in this toilsome journey; but we must refer the reader to Jackson's *Account of Morocco*, for a more particular and very interesting narrative of their perilous progress. The articles, which they transport to Tombuctoo, are linens, muslins, silks, light hayks, red caps, spices, sugar and tea, but chiefly tobacco and salt; and the produce, returned from Soudan, consists principally of bars of gold, gold dust, and gold trinkets, (in the manufacture of which the natives of that country display the greatest ingenuity,) elephants teeth, gums, and slaves, besides ambergris and ostrich feathers, collected by the way on the confines of the desert.

The commercial intercourse between the north of Africa and the kingdoms of Europe is extremely limited and fluctuating; and the treaties, which have been formed, at different periods, between the trading nations of Christendom and the piratical states of Barbary, were intended rather for securing protection from the African corsairs, than for promoting a mutual exchange of commodities. The instability and tyranny of the several governments in Barbary must still be regarded, as an almost insuperable obstacle to the industry of the

VOL. III. PART I.

natives, and to the confidence of foreigners. The wants of the inhabitants also are few and simple; and those habits of luxury, which are the great springs of commerce, are either altogether unknown among them, or, at least, restrained from open indulgence, by the lawless acts of extortion to which every opulent individual is invariably exposed. The little foreign traffic, which the people, or rather the rulers of Barbary do carry on, has been chiefly engrossed, of late years, by the French, Americans, and British. The principal articles imported into the north of Africa, are, broad-cloths, linens, muslins, silks, metals, hardware, mirrors, sugar, tea, gun-powder, and Mexico dollars; and those hitherto exported are, gums, almonds, dates, aromatic seeds, ivory, leather, hides, ostrich feathers, olive-oil, wax, and wool. The former, it is to be observed, are chiefly manufactured goods, and the latter, raw materials, of the most essential use in the manufactures of our own country. It has, therefore, been strongly urged by those, who are most competent to judge of the subject, that a close connection between Great Britain and Barbary might be of the very greatest advantage, both in a commercial and political point of view; that it would provide a most abundant supply of provisions for our fleets in the Mediterranean, and our troops at Gibraltar; as well as open a way for our manufactures into the very heart of Africa. It has likewise been shewn, that the northern states of that country are more inclined, than ever, to encourage such an intercourse; and that nothing is wanting to establish it on a solid foundation, than proper attention and respect on the part of the British government, and especially the appointment of agents, well acquainted with the language and manners of the people. It has also been suggested, that the inhabitants of South Barbary, in particular, are very favourably disposed towards the British; that a purchase might be made from the emperor of Morocco of his most distant and disaffected province of Suse; that at least, in consequence of his alliance, a British factory might be established at Agadeer (Santa Cruz), which would afford security both to the African and European trader, accustom the natives to the appearance and manners of foreign residents, become in a short time the emporium of Barbary and Soudan, and open a path for the progress of civilization and knowledge over these extensive regions of barbarity and ignorance. See *Letters from Barbary*, &c. Abbé Poiret's *Travels in Barbary*. Shaw's *Travels in Barbary*. Chenier's *State of Morocco*. Lempriere's *Tour to Morocco*. Bruce's *Travels*, vol. i. Jackson's *Account of Morocco*. *Mod. Univ. Hist.* vols. xviii. and xliii. (q).

BARBER, one who trims or shaves the beards of other people, or is employed in dressing hair or making wigs. This profession, like all the other *polite* arts, is only known in those nations, which have made a certain progress in civilization. No mention is made of barbers by any Roman author till the 454th year of the city; but there, as elsewhere, when they were once introduced, they soon became men of great notoriety, and their shops were the resort of all the loungers and news-mongers in town. Hence they are alluded to by Horace as most accurately informed in all the minute history both of families and the state:

“Omnibus et lippis notum et tonsoribus esse.”

These convenient gentlemen seem to have been almost exclusively entrusted with the important care of adorning the persons of the public; for not only the hair and

beard, but likewise the nails, received new grace from their skillful hands. Nor did their usefulness terminate here. They likewise handled the lancet with great delicacy; and had sometimes the honour of breathing a vein, or of dressing an wound,* to persons of high rank and fashion. Amidst these numerous avocations, it frequently happened that their customers were obliged to wait long before they could be attended to: and to prevent them from becoming impatient, the shops were provided with musical instruments with which they might entertain themselves; the more interesting amusement of newspapers being yet unknown. Much learning has been spent in endeavouring to account for the origin of the barber's pole. Some writers, from an excessive fondness for simplifying, have referred it to the word *poll* or head. But, in truth, this party coloured staff was intended as an indication of the dignity and variety of the profession practised within, intimating, emblematically, that the master of the shop was not a barber merely, but likewise a surgeon. Barbers were incorporated with the surgeons of London, but with no licence to practice any branch of surgery, except drawing teeth and letting blood; 32 Hen. VIII. c. 42. They were degraded, however, from this honourable association by the 13 Geo. II. c. 15. (e)

BARBORA, or BARBARA, an island on the eastern coast of Africa, situated opposite to a town of the same name in the kingdom of Adel. The inhabitants, who are negroes, employ themselves in trade and in the breeding of cattle. The island is very fertile, and produces corn and fruits in abundance. (j)

BARBOUR, JOHN, archdeacon of Aberdeen, is supposed to have been born about the year 1316. "When he describes the person of Randolph," says lord Hailes, "he seems to speak from personal observation: and as Randolph died in 1331, and Barbour in 1396, the poet, if we suppose him to have lived to the age of eighty, would be in his fifteenth year at the death of that illustrious warrior." (*Annals of Scotland*, vol. ii. p. 3.) Barbour was educated for the clerical profession; and in 1357 we find him styled archdeacon of Aberdeen. During that year the bishop of his diocese nominated him one of the commissioners who were to meet at Edinburgh, in order to deliberate concerning the ransom of their captive monarch, David II. (*Rymer*, tom. vi. p. 39.) Of the same date there is extant a passport from Edward III., which authorises him to visit the university of Oxford in company with three students. (*Ibid.* tom. vi. p. 31.) It has been supposed by Mr Warton, that he himself studied in this seminary during the years 1357 and 1365; (*Hist. of English Poetry*, vol. i. p. 318.) but for this supposition there is no just foundation. As he was then a dignitary of the church, he had certainly completed his academical studies. It would appear that,

* "An wound." We neither write nor speak thus in the United States. We say *a wound, a house, a yard*, and not *an wound, an house, and an yard*. In those words, we consider the *w* the *y* and the aspirate *h* as *quasi consonants*, and the *hiatus* between them and a preceding vowel as by no means unpleasant to the ear. On the contrary, we think that it would produce a most barbarous effect, were an actor or a reader thus to recite the well known line in Shakspeare's Richard III.

An horse! an horse! my kingdom for an horse,

DUPONCEAU.

in 1365, he visited St Denis, near Paris, in company with six knights. The object of their expedition seems to have been of a religious kind; for the king of England grants them permission to pass through his dominions, on their way towards St Denis and other sacred places. (*Rymer*, tom. vi. p. 478.) About ten years afterwards he was engaged in composing the celebrated work which has perpetuated his fame, an Historical poem on the Actions of the great King Robert. As a reward of his poetical merit, he is said to have received from the exchequer a pension which he enjoyed during his own lifetime, and which at his decease was transferred to the hospital of Aberdeen. (Hume's *Hist. of the House of Douglas*, p. 30.) From some passages in Winton's chronicle, it would appear, that he also composed a genealogical history of the kings of Scotland; but of this work no manuscript is known to be extant. Barbour, as has already been hinted, died in the year 1396. (*Chart. Aberdon.* f. 115. MS.) Of his *Bruce* there are many editions; but the most valuable is that of Mr Pinkerton, published at London in 1790, in three volumes octavo. This curious production is one of the oldest reliques of Scottish poetry; and in a historical point of view, it is likewise of very considerable importance. It clearly evinces, that the author was a man of no ordinary learning or genius. The humanity of his sentiments, and the liberality of his views, seem of a far more modern date than the fourteenth century; and he has diffused over his narrative that lively interest which an ordinary writer is incapable of exciting. See Irving's *Lives of the Scottish Poets*, vol. i. p. 253. (e)

BARBUDA, or BERBUDO, or BARBUTHOS, one of the Caribbee islands in the West Indies, belonging to the Codrington family. It is about 21 miles long, and 12 broad, and is encircled with a rocky coast. The industry of the inhabitants supplies the neighbouring islands with cattle, sheep, fowls, and corn; and the soil is capable of yielding the various fruits and trees which are produced in the other West India islands. The island abounds in serpents, some of which are very large, and others poisonous. The island is said to yield an annual revenue of 5000*l.* Population 1500. West Long. 61° 50', North Lat. 17° 49' 45". (π)

BARCA, a district of northern Africa, bounded on the north by the Mediterranean, on the south by the Sahara or Desert, on the east by Egypt, and on the west by the kingdom of Tripoli. It extends in length about 690 geographical miles, from 18½ to 31 East Long.; and in breadth about 180 miles, from 28 to 31 North Lat. The etymology of the name is extremely uncertain. It has been explained as signifying "a blessing," and derived from the Arabic *barac* "to bless." Others have considered it as taken from Barca, a brother of queen Dido, who is supposed to have founded the city of Barca. The modern Arabs, however, are said to understand it as denoting "the place of hurricanes." In ancient history it formed a part of that immense tract of country, which bore the general name of Libya; and was then divided into two provinces, which were called Libya Cyrenaica, and Libya Marmarica.

The modern state and history of Barca are very imperfectly known. It is described as a tract of dry barren sand, almost entirely destitute of vegetation, incapable of culture, and rarely yielding a spring of fresh water. A few spots of verdure, consisting chiefly of the different kinds of kali or glasswort, occasionally relieve the eye of the traveller, and furnish a slender refresh-

ment to his suffering camel. At long and dreary intervals are found some fertile places, called oases, or islands, where the towns and villages are situated, and where a little millet, maize, and sometimes abundance of dates are produced. In many of the more desert parts, the surface of the ground is covered with a saline crust; and, in the regions towards the south, great quantities of petrified wood of various forms and sizes, even large trunks of trees, particularly of oak, are found in the sand.

The principal towns along the coast of the Mediterranean are, Zoara, Soluk, Bernic, Bengasi, Tauchira, Tolemata, (*Ptolemais*.) Barca, the capital of the country, Curin (*Cyrene*.) Derna, Cape Luco (*Promontorium Carylonium*.) Porto Mesulman (*Calabthmus*.) Rameda, Bareton (*Paretonium*.) The inhabitants of these maritime places, in their general character and customs, resemble the other natives of Barbary. They profess the religion of Mahomet; are considered as under the protection of the Porte; and are tributary to the Basha of Tripoli or of Egypt, according as they approximate to either of these kingdoms; but very little is known respecting their political state, or commercial intercourse.

The Barcan desert is separated from the Libyan, on the south, by a chain of rocky mountains, among which the most considerable towns and villages are situated; and where the climate and soil are more favourable, than in any other part of the country. The chief of these towns, which have been noticed by travellers, are, Mogara, Ummegeir, Biljoradeck, Siwah, where very extensive ruins have been observed, and where the oracular temple of Jupiter Ammon is supposed to have been situated; Mojabra, Melidilla, and Augila, which is mentioned by Herodotus as being ten days journey from the city of the Ammonians, and which has been remarkable, both in ancient and modern times, for the great abundance and superior flavour of its dates. The houses in these towns are generally placed on the side of the mountains, and have very much the appearance of caves in the rocks. The soil in their neighbourhood yields pomegranates, figs, olives, apricots, plantains, a little wheat, a considerable quantity of rice of a reddish hue, but principally dates. A few sheep, goats, asses, oxen, and camels, are kept by the natives; but, for want of pasture, the cattle are frequently supported by the fruit of the date tree. The inhabitants are engaged chiefly in agriculture and gardening; and sometimes carry on a petty traffic with the Arab caravans from the cities on the coast, or with those which pass between Fezzan and Egypt. Some of them, by these means, acquire considerable wealth; but they are in general remarkably poor and dirty. They are frequently almost entirely naked; and their dress, at most, consists only of a large wrapper of coarse woollen cloth. Sometimes, under this, they wear a white cotton shirt with wide sleeves, reaching to the feet, a Tunisian cap of red worsted or cotton, characteristic of the Mussulman, and slippers of the same colour. They subsist chiefly upon dates, rice, milk, flat cakes of unleavened bread, or thin sheets of paste, fried in the oil of the palm tree. They drink great quantities of a liquor made from the date tree, which they term *date-tree water*; but which has often, in the state in which it is used, an inebriating quality.

Of the more central parts of Barca, scarcely any thing whatever is known. Few travellers have attempted to explore its pathless wastes of barren and burning sand;

where they could have no other guide than the compass or the stars, and where they would be continually exposed to the cruel rapacity of the most savage and brutal of all the Arab race. The few wandering tribes who traverse these dismal regions, are described as peculiarly hideous in their aspect, ferocious in their manners, meagre and ravenous in their whole appearance. They are wretched and indigent in the extreme; and subsist principally by plundering the date villages, and levying contributions from the caravans, which pass along the coast of the Mediterranean, or by the borders of Libya. They are almost continually engaged in these predatory excursions; and are said to commit the most atrocious acts of cruelty upon those who fall into their hands. Yet, with all their exertions and expertness in robbery, they are said to be frequently in such a famishing state, as to pledge, or even sell, their own children, for the necessities of life, to the Sicilian and other Christian traders, who occasionally come upon the coast. See *Ancient Univ. Hist.* vol. xviii. p. 228. *Modern Univ. Hist.* vol. xviii. p. 518. *Brown's Travels in Africa.* Hornemann's *Travels in Africa.* (g)

BARCAROLLA, the name of the airs sung by the Venetian Gondolieri. (w)

BARCELONA, the *Barcinona* of the Romans, is the capital of the province of Catalonia, and one of the principal cities of Spain. It is situated on the Mediterranean, between the rivers Bezos and Llobregat, in a beautiful and fruitful country, which forms an oblong irregular plain, encircled with hills on one side, and bounded by the sea on the other.

Barcelona was founded about 250 years before Christ by the Carthagenians, who called it after their general Hannibal Barcino. After having passed under the dominion of the Romans, the Goths, and the Moors, Barcelona was besieged in A. D. 802, by the generals of Louis, king of Aquitania. Having opposed a heroic resistance for seventeen months to the continual assaults of the besiegers, it yielded to the French arms after its walls were demolished, and one half of its inhabitants destroyed by famine or the sword. In the year 985 it was taken by the Moors, who burned the city, and carried into slavery almost all the inhabitants; but it afterwards fell into the possession of Count Borel. The rebellion of the Catalonians in 1465 against Don Juan, king of Arragon, was fostered in the capital of the province. The king besieged it in vain in 1462; but on the 17th October 1472, after a siege of six months, it yielded to the superior force which he brought against it. The revolt of the Catalonians in 1640, exposed Barcelona to new dangers. It maintained its independence for twelve years against the arms of Philip IV.; but it was at last taken by Don Juan of Austria in 1652, after a blockade and siege of ten months. In 1689 it opposed an ineffectual resistance to Charles II. In 1697, fifty days after the trenches were opened, it was taken by the French under the Duke of Vendome, though the bravery of the inhabitants was seconded by a garrison of 12,000 men under the Prince of Darmstadt. Although the citizens had sworn allegiance to Philip V., they invited the English and Dutch to deliver them from his yoke. The city yielded to the allied arms, and Charles, afterwards emperor, was proclaimed king. In 1704, Philip, aided by the French, besieged Barcelona in person, and took the fortress of Montjouy; but the English fleet compelled him to raise the siege on the 12th of May. In consequence of the treaty of Utrecht in 1713, Catalonia and

the neighbouring provinces resumed their allegiance to Philip V.; but Barcelona refused to join in the universal submission, and in 1714 sustained one of the most memorable sieges that history has to record. Feats of heroism, worthy of the best ages of Rome, and efforts of individual courage, which have perhaps never been surpassed but by the modern inhabitants of Zaragoza, distinguished that dark and bloody night, in which the streets and houses of Barcelona were filled with the mangled bodies of its warriors.—May the same spirit again animate their children, who are at this moment armed for a more arduous struggle, and in a more glorious cause.

The city of Barcelona is defended on one side by the shallowness of the sea, and on the other by numerous bastions, the approaches to which are guarded by many advanced works. Its chief defence, however, is the citadel, which was erected in 1715 at the north-east point, to overawe the inhabitants, and the fort of Montjouy on the top of a mountain at the south-east point. The ramparts, called the sea wall and the land wall, embrace about three-fourths of the town, and form a superb terrace, from which there is a delightful view of the town and the surrounding country. At the end of the land wall is the esplanade, a large open piece of ground turfed and planted with trees, and extending from the new gate to the citadel. A handsome walk through it, about 444 yards long, was finished in 1801.

Though some of the streets of Barcelona are sufficiently spacious, yet, in general, they are narrow and crooked. The town abounds in squares, which are small and irregular. The largest of them is very spacious and elegant, decorated on one side by the governor's palace, on the opposite side by the exchange, on the other by the sea gate and the customhouse, and on the north by a row of good houses. The architecture of the houses is, in general, pleasing and simple; they are about four or five stories high, having large windows with balconies. Most of the houses which have been built within the last thirty years, have their fronts adorned with paintings in fresco.

The public buildings of Barcelona are remarkable, both on account of their external beauty, and the curiosities which they contain. The cathedral church, about 160 feet long, and 62 broad, has a magnificent appearance. Twelve large Gothic pillars separate the nave and aisles, and are formed by clusters of columns of various sizes. A large octagon dome of Gothic architecture, with eight galleries, stands in the middle of the space between the choir and the great door. The sanctuary, which stands over the subterranean chapel, containing the relics of St Eulalia, is formed by ten pillars, forming a semicircle, which contains the great altar, in the Gothic style, and of exquisite workmanship. The convent of La Mercè has a large church, with a Doric portal, and a fine front composed of two stories of Corinthian and Ionic architecture. The cloister, which is sixty feet square, is most superbly executed. The portico, of sixteen arcades, which surrounds it, is supported by twenty Doric columns of marble. Above the portico is a spacious gallery, which has, on the outside, thirty-two arcades, on Ionic columns of marble, ornamented with a ballustrade of grey marble. The convent of St Francisco has a large and handsome Gothic church, and a cloister, adorned with paintings. The convent of the Dominicans, and the chapel of St Raymond, are scarcely deserving of notice. The chapel of our Lady of the Rosary, has two cloisters, one of which

has its walls covered with paintings, put up by the Inquisition, in 1745, to preserve the memory of the numerous victims of that bloody tribunal. Bodies writhing in the midst of flames; devils running off with bodies; and inscriptions containing the designation and punishment of the culprits, attract the notice of strangers. Above one of the doors of the cloister is a large inscription, stating, that the monuments of the punishment of those who were condemned were formerly deposited there; but that the ravages of time and of war had destroyed these precious relics, and induced the inquisition to perpetuate their remembrance upon canvass. The parish church of St Mary of the Sea, built in the fifteenth century, is the finest in Barcelona. The principal altar is a rich assemblage of white, black, and mixed marble. The Hotel-de-ville contains a variety of excellent pieces of sculpture. The hotel of the Deputation, where the States of Catalonia assembled, is reckoned one of the handsomest edifices in the city, and contains the archives and charters of the crown of Arragon. The palace of the Counts of Barcelona and the Kings of Arragon, distinguished by the noble simplicity of its architecture, serves for the prisons of the inquisition, and the academy of medicine. The governor's palace was built in 1444, as a market for cloths. It was converted into an arsenal in 1514; and in 1652, Philip IV. made it the residence of the Viceroy of Catalonia. The exchange is a rectangular building, 230 feet long and 77 wide, and has a noble and majestic appearance. The customhouse, the theatre, and the school for surgery, are the only other buildings deserving of notice. Besides these public buildings, there are six hospitals, a charity-house, and an asylum. The poor employed in the asylum amounts to 1400, of which 300 are maniacs. The university of Barcelona was suppressed at the beginning of the tenth century, by Philip V. It is now turned into barracks. Besides a private collection of natural curiosities, and two public libraries, there are four academies, viz. of natural philosophy, history, practical medicine, and jurisprudence.

The remains of those superb buildings, with which the Romans decorated Barcelona, have almost wholly perished. The only antiquities which are now to be seen, are, 1. The remains of a Mosaic pavement composed of white and blue stones, representing fishes and tritons. 2. A lofty and massy arch of an aqueduct, which seems to have conveyed water from the mountain of Colserola. 3. A basin of white marble in the house of the archdeacon near the cathedral, having its front covered with reliefs. 4. Six large fluted columns, with capitals of the Corinthian order. These columns, which are 29 feet 10 lines high, form part of the walls of a house. 5. Several ancient pieces of sculptures in the court walls of a house belonging to the Pinos, in the square of Cucurulla. Among these, there is a little statue of Bacchus, without the head, of beautiful workmanship.

The festivals and ceremonies of the church are particularly brilliant at Barcelona. Those which take place during the holy week are the most remarkable, and some idea of their grandeur may be formed from the immense quantity of wax which is then consumed. In the three processions there are burned nearly 30,000 flambeaux of white wax, each of which weighs about five or six pounds. Though the greater part of this wax comes from Africa, it is still a great branch of trade and industry.

The harbour of Barcelona is formed by a kind of bay, situated between the citadel of Montjouy and the city. At the beginning of the sixteenth century it was merely an open coast, with considerable depth of water. At present it is only a great basin, formed by piers, and kept up by solid quays. Notwithstanding the exertions which are made to keep it clear, the basin is gradually filling up with sand. Ships of any considerable size cannot at present be admitted, and frigates cannot come within half a league of it. The entrance to the harbour is difficult, and occasionally dangerous, in consequence of a high bar formed at the place where the waters of the Bezos and the Llobregat mingle in the sea. The harbour of Barcelona, notwithstanding these disadvantages, is secure and well-sheltered, and is always crowded with the ships of different nations. A few years ago, the total number of vessels, in one year, was 500 Spanish, 150 English, 60 Danes, 45 Dutch, 2 French, and more than 300 of other nations, amounting to at least 1060 vessels.

The situation of Barcelona has rendered it one of the most flourishing and commercial towns in Spain. About a thousand Spanish ships, of which nearly 120 belong to Barcelona, annually clear out of the harbour, and carry to America, and to the different maritime kingdoms of Europe, the productions and the manufactures of Catalonia. The articles of the export trade are silver, gold, and plain stuffs, silk stockings, middling cloths, printed calicoes, striped and flowered cottons, cottons of all kinds, plain and stained papers, fire-arms, laces, shoes, wines, and brandies. The articles which it imports are, silks from Lyons and Nismes, silk stockings from Nismes and Ganges, cloths from Elbeuf and Sedan, jewellery from Paris, iron-ware from Forez, millinery from France; and cotton goods and dried cod from England. The export and import trade is said to amount annually to 1,750,000*l.* sterling.

The cotton goods manufactured in Barcelona produce annually 442,510*l.* sterling. Of these, one-twelfth is consumed in Barcelona, two-twelfths in the other provinces of Spain, and two-thirds are shipped for the Spanish colonies. The exports from the province amount to 375,000*l.* sterling. No fewer than 700,000 pair of shoes, at 2*s.* 1*d.* the pair, are exported to Spain, India, and the Spanish colonies in America.

Between the 13th and 16th centuries, cloths made of woollen, linen, silk, cotton, and hemp, were manufactured in Barcelona. After a long interval of inactivity, its manufactures revived about the middle of the 18th century, and are now flourishing beyond all former example. The principal articles are printed calicoes, silk, silk stockings, ribbons, and silk galloons. No fewer than 214 manufactories are employed on printed cottons, 524 looms on silk stuffs, and 2700 looms on ribbons and silk galloons. The articles manufactured from silk are, taffetas, twilled and common silks, satins, and velvets. Besides these articles, laces, blonds, network, and tapes, are manufactured to such an extent as to occupy about 12,000 persons. Galloons, laces, gold and silver fringes, and silk gold and silver embroideries, are likewise made. Among the manufactories recently established are, several for hats, two for stained paper, one for gauzes like blond lace, one for glass, one for cotton stuffs, and a magnificent establishment for the foundry of cannon. Cotton spinning was introduced about the year 1790, and it employs about 4000 looms, and 10,700 persons. No less than 120,700 pieces,

or 2,896,871 French ells of cotton stuffs of various kinds, are annually manufactured, to the value of 242,510*l.* sterling.

The climate of Barcelona does not seem to be so mild as was formerly believed. The air is constantly charged with humidity, and the east winds are very prevalent. Formerly snow never fell at Barcelona, but at present it snows every year. The spring is always the worst season of the year. The intense heat of summer is moderated by the east wind; and the changes of temperature are both great and sudden. Autumn is the most delightful season.

The following is an accurate statement of the population of Barcelona, including Barcelonetta:

In 1715	37,000
1769	54,000
1787	111,410
1798	130,000
1806	160,000

The number of families amounts to 20,508, the number of houses to 10,767, the churches to 82, and the convents to 50. East Long. 2° 13', North Lat. 41° 26'. See Laborde's *View of Spain*, vol. i. p. 27. Bourgoing's *Travels in Spain*, chap. xxxiii. Townsend's *Travels*, vol. ii. p. 374. Reichard, *Guide des Voyageurs en Europe*, vol. i. p. 79; and *A Tour in Spain and Portugal in 1803*, chap. i. published in Philips's *Voyages and Travels*, vol. iii. See also CATALONIA, where we shall give a full view of the trade of that flourishing province, as communicated to the editor by a gentleman who has resided in that country. (π)

BARCELONETTA, the name of a new town adjacent to Barcelona. It is situated to the southeast of the city, between the sea-gate and the lighthouse on the mole, and was built about the middle of the eighteenth century. It is a complete square, with twenty-four regular streets, each about twenty-five feet broad. Fifteen of these are direct and parallel, and are intersected at equal distances by nine streets. The houses, which are built of brick, are all one story high, and of the same height and width in front. The uniformity of the streets are a little varied by two squares. The inhabitants are chiefly soldiers, sailors, and people connected with the navy. Population 15,000. (π)

BARCLAY, ROBERT, of Ury, generally known by the title of the APOLOGIST, was the eldest son of Colonel David Barclay, and descended through a long line of ancestry from Theobald De Berkely, who lived in the time of David I. He was born on the 28th December 1648, at Gordonston, in Morayshire, the seat of his maternal grandfather. After being educated in the best schools in Scotland, he was sent to Paris, and placed under the tuition of his uncle, who was rector of the Scots college. He gave early presages of great genius, and acquired much proficiency in all the learned sciences and elegant accomplishments of the times. He soon became conspicuous in the college; and was particularly noticed for his vivacity and acuteness in the public disputations of that seminary, where he gained many prizes. His uncle admired his talents, and offered to leave all his fortune to him, which was very considerable, if he would remain in France; but his mother, on her deathbed, had strongly enjoined his removal from the college, lest he should imbibe the errors of popery. In obedience to parental authority, he

returned home in 1664, and thus lost his uncle's fortune and favour to gratify his father's conscientious compliance with the prejudiced, but pious notions of his mother. Though destitute of wealth, he possessed what was more valuable; for his mind was deeply fraught with the riches of learning and literature.

Soon after his return to Scotland, he joined the society called Quakers, and became their greatest ornament and ablest advocate. Previous, however, to his embracing the opinions of that sect, he visited his friends of all religious persuasions to canvass their doctrines, that he might adopt a system of faith corresponding to the truths of the gospel, and by conviction alone, as we are informed, he was guided in his choice.

In the year 1670, he was married to Christian Molison, of the family of Lachintully, the grand daughter of the celebrated Colonel Molison, who so much signalled himself in the defence of Candia against the Turks. And about this time, he first appeared as an author, by a work, entitled, *Truth cleared of Calumnies*, which is an answer to *A Dialogue between a Quaker and a stable Christian*, written by William Mitchell, a preacher, and printed at Aberdeen. A keen controversy then subsisted between the clergy of Aberdeen and the Quakers, relative to the doctrines of the latter, which warmly interesting Barclay, called forth his talents as a polemical writer; and in the same year he published a postscript in the form of questions. Mitchell replied to *Truth cleared of Calumnies*, and our author again answered him, in a work entitled, *William Mitchell unmasked*, which was published in 1672. In this controversy, Robert Barclay discovers his variety of learning, and that he was well acquainted with ecclesiastical history; but above all, he shows, with how much judgment and dexterity he could apply his knowledge in support of his religious opinions.

In 1673, he published *A Catechism and Confession of Faith*, which is an exposition of the doctrines and principles of the Quakers, supported by an appeal to Scripture testimony. His next publication is the *Theses Theologicae*, which were addressed "to the clergy of what sort soever," and contains fifteen propositions, on which he gives his sentiments, and explains them in conformity to the principles of his sect. He vindicated the Theses from the strictures of Nicholas Arnold, professor in the university of Franeker in Friesland, by a Latin treatise printed at Amsterdam in 1675. In the same year he published an account of a disputation between the students of divinity of the university of Aberdeen and the Quakers, in which he bore a conspicuous part; but it seems to have terminated without satisfaction to either party. The students also published an account of this conference in a pamphlet entitled, *Quakerism Canvassed*, which occasioned a reply, entitled *Quakerism Confirmed*, in two parts, both printed in 1676.

Previous to this time, he generally resided at Ury with his father; but in this year he went to London, and from thence to Holland, accompanied by William Penn, the celebrated proprietor of the province of Pennsylvania. These religious men travelled in Holland and Germany, visiting their friends, and disseminating their doctrines. They waited upon Elizabeth, princess palatine of the Rhine, at her residence at Herwerden, and were kindly received. She seems to have adopted their opinions, for she openly patronised the Quakers; but her friendship for Barclay was sincere and unfeigned,

and lasted during life. She frequently wrote to him with her own hand; and always promoted his views at the court of England as far as her influence could be of service to him or his friends. When he returned to London, he learned that his father and other Quakers were imprisoned in Aberdeen for holding meetings in that city. He therefore presented a memorial in their behalf to Charles II., which was delivered by himself into the king's own hand, who caused his Secretary of State, the duke of Lauderdale, to underwrite upon it a favourable reference to the council of Scotland, which had the desired effect, as they soon after obtained their liberty.

In this year (1676) he published "*The Apology for true Christian Devotion*," in Latin, at Amsterdam, which is the most celebrated of his works. It is dedicated to King Charles the II. The dedication is remarkable for the freedom and boldness of sentiment and language in which his majesty is addressed. "Thou hast tasted," he says, "of prosperity and adversity. Thou knowest what it is to be banished thy native country; to be overruled, as well as to rule and sit upon the throne; and being oppressed, thou hast reason to know how hateful the oppressor is both to God and man. If, after all these warnings, and advertisements, thou dost not turn to the Lord with all thy heart, but forget Him who remembered thee in thy distress, and give up thyself to folly, lust, and vanity; surely great will be thy condemnation." "*The Apology*" is reared on the "*Theses Theologicae*," being an exposition of the fifteen propositions contained in that work. The author's general plan is, to state the position he means to establish, and to support it by scripture quotations applicable to the case, or to deduce the truth of it by an argument in the form of a syllogism. By this learned work he acquired great celebrity, as a deep theologian, profoundly skilled in the scriptures, the fathers, and church history. His next publication, which also appeared this year, is entitled, the "*Anarchy of the Ranters*," and it is a vindication of the society from the imputation of disorderly parties in their discipline, of which they were accused by their adversaries.

About the end of September, the Apologist returned to Ury; and although he had obtained his father's release from confinement, he was not able to protect himself. On the 7th November 1676, he was committed to prison in Aberdeen along with several other Quakers, for holding meetings for public worship; and did not regain his liberty until the 9th April 1677. While in prison he wrote a treatise entitled, "*Universal Love considered and established upon its right foundation*," which was published after his release.

He left Ury in May, and went to London to exert himself for the deliverance of the Quakers of the north, who were still harassed by imprisonment and fines, for holding meetings at Aberdeen in contravention, as it was alleged, of a statute enacted against *armed field conventicles*; which evidently did not apply to these peaceable people. From *Theobald's near London*, he wrote to the Princess Palatine on this subject, in which he gives an account of a conversation that had passed between him and the Duke of York relative to the sufferings of the Quakers. It appears by this letter, that he had addressed his Royal Highness in very plain language, for he says, "I told him, I understood from Scotland, that, notwithstanding Lauderdale was there, and had promised to do something before he went, yet our friends' bonds were rather increased; and that

there was only one thing to be done, which I desired of him, and that was, to write effectually to the Duke of Lauderdale, in that style wherein Lauderdale might understand that he was serious in the business, and did really intend the thing he did write concerning should take effect; which I knew he might do, and I supposed the other might answer; which if he would do, I must acknowledge as a great kindness. But if he did write, and not in that manner, so that the other might not suppose him to be serious, I would rather he would excuse himself the trouble; desiring withal to excuse my plain manner of dealing, as being different from the court way of soliciting: all which he seemed to take in good part, and said he would write as I desired." He soon after returned to Ury, and was permitted to enjoy the full exercise of his religion unmolested, until the 9th November 1679, when he was taken out of a meeting at Aberdeen, as well as several of his friends; but they were discharged in a few hours, and never afterwards disturbed by the magistrate.

"The Apology," which had become widely circulated in six different languages, was rudely assailed by John Brown, in a work entitled, "*Quakerism the Pathway to Paganism.*" To this abusive performance, Barclay replied in vindication of his doctrines, which is the last of his polemical writings that are published. From this period, he was occupied for the most part, in travelling in England, relative to the concerns of the society; and when in London, in 1682, he was honoured with a public appointment, having received a commission as governor of East Jersey in America. An extensive tract of land in that province was, at the same time, granted to him and his heirs in fee. Charles II. confirmed his government for life, and the commission is expressed in terms highly flattering to this good man: "Such are his known fidelity and capacity," it says, "that he has the government during life; but that every governor after him shall have it for three years only." He was authorised to appoint a deputy-governor, with a salary of 400*l.* sterling per annum; and Gawn Laurie, a merchant in London, was accordingly appointed to that office. Having arranged these matters, he returned to Ury: but in summer 1683, he again visited his friends in London. Towards the close of that year, however, he came home, and occupied himself in shipping stores, provisions, and other necessaries, from Aberdeen to the colony of East Jersey; in the prosperity of which, he was extremely interested.

In 1685 he went again to London relative to the concerns of the society; but he soon returned, and remained at home until April 1687, when, at the earnest solicitation of George Fox, and other friends, he set off for court, to exert his influence in behalf of the Quakers. As the king honoured him with his friendship, he had access to his majesty at all times; and, on this occasion, he presented an Address from the Quakers in Scotland, expressive of their gratitude for his majesty's proclamation permitting liberty of conscience; which was graciously received. The apologist seems to have stood on a footing of great intimacy with the king, and to have conversed with him candidly and freely on the business of the state. Considering the intricacy of his majesty's affairs at that time, the opinion or advice of a sincere and honest, yet clear-headed man, was no doubt highly valued by James. Having accomplished in London the object of his journey, he returned home.

In November 1688, he was again in London, and embraced that opportunity to take leave of his majesty, with whose misfortunes he was greatly affected. At his last interview with the king, while they were standing at a window in the palace, conversing together, James looked out and said, "The wind is fair to bring over the Prince of Orange;"—the apologist remarked, "It was hard that no expedient could be fallen upon to satisfy the people."—His majesty replied, "He would do any thing becoming a gentleman, but never would part with his liberty of conscience." This sentiment was so consonant to the apologist's mind, and corresponded so closely with his own principles and practice, that it drew forth his approbation; and with mutual regret they parted to meet no more.

In the month of December he arrived at Ury, and lived retired for nearly two years, enjoying domestic happiness in the bosom of his family. But having gone to Aberdeen about the end of September 1690, to attend a meeting of Quakers, he caught cold while returning to Ury, and being seized with a fever, it put a period to his life on the 3d of October, after a short but severe illness.

With a mind naturally strong and vigorous, he possessed all the advantages of a regular and classical education; and his writings evidently show the profundity of his research, as well as the extent and variety of his learning. His mild temper, benevolent heart, and sprightly conversation, gave him influence with men in elevated stations; but he employed it only for the benefit of his friends, and often successfully exerted himself in behalf of others, as well as for the members of the society to which he belonged, from motives of pure benevolence. If, on one occasion, he inconsiderately betrayed a fervour of zeal in his profession of a preacher, by exposing himself in sackcloth on the streets of Aberdeen, in the year 1672, we must concede to him, at least, the merit of sincerity; and, in justice, make every allowance for the ardour of a youthful mind. Although his feelings were warm, yet his passions were subdued by strict discipline; and the practical observance of the rules of moral duty strengthened and invigorated every virtuous sentiment. Cheerful, yet serene, he withstood the shocks of a chequered life with fortitude and firmness. Ever active and indefatigable, he composed one of his best works within the walls of a prison; and, in all situations, he was constantly occupied with that which he conceived to be for the good of mankind. Considering the shortness of his life, and the time he employed in travelling, it is astonishing that he could write so much, and so well. But his works have outlived him; and, in three volumes, the scattered opinions of the society to which he belonged are collected, arranged, and exhibited to the whole world in elegant uniformity; and throughout Europe and America, "The Apology for true Christian Divinity" is to be found in the libraries of the wise and learned. See two Manuscripts preserved in the Library of Ury, and the author's printed *Works*. (τ)

BARD, a professional poet and musician of ancient times, whose office it was to celebrate, in song, the mighty deeds of the heroes of his nation, or to lament in pathetic strains, their untimely loss, or any great public calamity. The term, according to Festus and Camden, is pure British or Celtic, and denotes a *singer*. The Celtic bards were a particular class of the Druids, or ministers of the national religion; but, taken in its

more general acceptation, the term bard denotes any professed musician and poet, or minstrel of ancient times.

We have very satisfactory evidence, that, during the heroic ages of Greece, the profession of a minstrel, or bard, was in the highest esteem. Homer makes honourable mention of Thamyris and Tiresias, two celebrated bards of those ages: and he describes, as one of the highest gratifications at the court of King Alcinoüs, the bard Demodocus, pouring forth, to the sound of the lyre, his lofty strains. Phemius, another bard, is introduced by Homer, as deprecating the wrath of Ulysses in the following terms:

“O king! to mercy be thy soul inclined,
And spare the poet's ever gentle kind;
A deed like this thy future fame would wrong;
For dear to gods and men is sacred song.” *Odys. 8.*

It can scarcely be considered as derogatory to this divine poet himself, to enrol him among a class of men anciently so highly honoured, if, as is justly his due, we place him foremost in the list of all the celebrated bards of antiquity.

Among the ancient Scandinavians and Germans, the recital of martial deeds, by the bards or minstrels, was a gratification which was very highly prized. Such recitals, according to Tacitus, inflamed the courage of the ancient Germans, and served them as omens of future warfare. Nor was it so much by the charms of harmony, as by the display of heroism, that the hearers were delighted; for, according to that author, a harshness of tone was affected, and the voice was rendered deeper, and more resounding, by the application of a shield to the mouth of the bard. “*Sunt illis hæc quoque carmina quorum relatio quem barditum vocant, accendunt unimos, futuræque pugne fortunam ipso cantu augurantur; terrent enim, trepidantque, prout sonuit acies. Nec tam vocis ille quam virtutis concentus videtur. Affectatur præcipue asperitas soni, et fractum murmur objectis ad os scutis, quo plenior et gravior vox repercussu intumescat.*” *De Mor. Germ.*

With respect to the honour in which the ancient inhabitants of Scandinavia held their bards, or *scalds*, as they were there denominated, we have the most ample testimony in their old chronicles. From them it appears, that the kings of Denmark, Sweden, and Norway, were constantly attended by their scalds or scalders, who were always treated with the highest respect. Harold Harfager placed these minstrels over all his other officers, and employed them in negotiations of the greatest importance. Haaco, earl of Norway, in a celebrated engagement against the warriors of Tomsburg, was attended by five bards, each of whom animated the courage of the soldiers, when about to engage, by a war song. Mention is made by Saxo-Grammaticus, in his description of a battle between Waldemar and Sueno, of a scald or bard belonging to the former, who advanced to the front of the army, and, in a pathetic strain of poetry, reproached Sueno for the unnatural murder of his father. Regnar, king of Denmark, was no less distinguished in poetry than in war; and Harald, the valiant, who flourished in the eleventh century, has immortalised himself by a beautiful poem, in which he complains, that, notwithstanding his numerous achievements, he is unable to subdue the scorn of a beautiful Russian princess.

Among the Celtic nations, the bards enjoyed equal, or still higher honours, and formed a branch of the religious establishment and administration of the state. In the ancient British kingdoms, they enjoyed by law or custom, many honourable distinctions, and valuable privileges. They as well as the Druids, were exempted from taxes and military services, even in times of the greatest danger. Their persons were held sacred and inviolable; and the most cruel and bloody tyrants dared not to offer them any injury. When they attended their patrons into the field, to record and celebrate their great actions, they had a guard assigned them for their protection; and at all festivals and public assemblies, they were seated near the king or chieftain, and sometimes even above the greatest nobility and chief officers of the court. Nor was the profession of the bard less lucrative than it was honourable. For, besides the valuable presents which they occasionally received from their patrons, they had estates in land allotted for their support. Such was the respect in which the bards were held, that, by a law of Howel Dha, it was enacted, that whoever struck any one of this order, must compound for his offence, by paying to the party aggrieved one-fourth more than was necessary to be paid to any other person of the same degree.

The chronicles of the ancient British states contain a store of curious information concerning the original constitution, functions, and privileges of this highly respected order. They seem to have been divided into two classes: The first, comprehending the sacred or religious poets, whose office it was to compose and sing hymns in honour of the gods; and to celebrate their peculiar and mysterious religious rites. These were called by the Greeks *Eubates*, by the Romans *Fates*, and in their own language *Faids*. The second class comprehended the secular poets, who were more peculiarly called bards, and celebrated in song the battles of heroes and the romantic achievements preserved by tradition. The number of these appears to have been very great. In the poems of Ossian we read of 100 bards belonging to one prince, singing and playing in concert for his entertainment. Every chief bard, who was called Allah Redan, or doctor in poetry, was allowed to have 30 bards of inferior note constantly about his person; and every bard of the second rank was allowed a retinue of 15 poetical disciples.

It appears that in Wales there was an annual congress of the bards, usually held at the royal residence, the sovereign himself presiding in the assembly. Here each was assigned a precedence and emolument suitable to his merit; but the bard most highly distinguished for his talents was solemnly chaired, and honoured with the badge of a silver chain. The bards, properly so called, were distinguished from the Druids, and from the Eubates, or Ovates, by the colour of their dress: they were clad in sky-blue garments, while the Druids wore white, and the Ovates green. Their disciples were arrayed in variegated garments, consisting of these three colours blended. There were four principal meetings of the bards held in the course of the year; viz. at the two solstices and two equinoxes. The first was at the winter solstice, which was the beginning of their year, and was called *Alban Arthan*; the second at the vernal equinox, called *Alban Eiler*; the summer solstice, or *Alban Herwin*; and the autumnal equinox, or *Alban Etuid*, following next in order. They assembled in circles of unwrought stones, placed so as to be indexes of the seasons, in the open air, and always when the sun was above the horizon;

or, as they expressed it, *in the face of the sun, and in the eye of the light.*

From these particulars it is plain, that the institution of bards among the Celtic nations had something farther in view, than the celebration of heroic achievements by music and song; they were the depositaries of the various kinds of knowledge then prevalent in their tribe, and of the authenticated records of the nation. When writing was unknown, oral tradition was the only method of preserving the memory of what was important; and the bards were an order of men trained on purpose to accomplish this end, and to deliver knowledge down to posterity in a form calculated at once to arrest the attention, and assist the recollection. In order that nothing should become current without due consideration, whatever was intended to be thus permanently recorded, was always laid before the grand meetings. It was there discussed with the most scrutinising severity; if then admitted, it was reconsidered at a second meeting; and it was not, till it had received the approbation of three successive meetings, or of the triennial supreme convention, that its admission was finally confirmed. At this great assembly, all that had been confirmed at the provincial meetings was recited, for the use of the disciples who were to commit it to memory; and what was thus solemnly ratified, was to be recited for ever afterwards; once at least in every year, in addition to the former bardic traditions.

Such was the well-organised system for preserving traditional knowledge, by the institution of the bards, an important branch of the system of Druidism, but which seems to have long survived that system, on account of its extraordinary means and precautions for self-preservation. It has been advanced, and with some appearance of probability, that bardism was the parent of free masonry; a character which it assumed, in order that its members might assemble in secret, and unsuspected. The term *ovyz*, or *ovate*, by which the third class of bards was distinguished, has the meaning of artizan or mason; and the free-masons preserve a traditional memorial of their meeting anciently on the tops of the highest hills, and in the bottoms of the deepest vallies, and when the sun was in its due meridian.

It was the cruel policy of Edward I. to command a general massacre of the Welsh bards, persuaded that nothing was more likely to maintain among the people a sentiment of military valour, and a passion for national independence, than the traditional legends of this class of men, who, like the ancient Tyrtæus, employed their animated strains, as a means of exciting the courage of their countrymen against the common enemy. The system of bardism, however, recovered much of its ancient vigour in Wales, during the short, but spirited insurrection of Owen Glendower. But when that effort for restoring the independence of the country was crushed, the bards were again proscribed and persecuted. They, however, again made their appearance, as the genealogists and minstrels of the great Welsh chieftains; a capacity in which they have enjoyed great honour and emolument, in every country where tradition was not entirely superseded by the general diffusion of letters. In Ireland, and in Scotland, every great family was possessed of its bard almost down to the present day. In the Highlands of Scotland, particularly, every *regulus* or chieftain had his family bard, who was regarded as filling a very important office, and who had lands assigned him, which descended regularly to his posterity.

The bards of ancient times do not appear to have been so highly honoured, or so liberally remunerated. We read, that Alexander the great was accompanied, in his expedition to India, by a poet, or bard, named Cherylus, who proposed to the hero to celebrate, in song, his mighty exploits. Alexander permitted him, only on condition that the poet should receive a piece of gold for every good verse, and a blow for every bad one. The scholiast Horace, to whom we are indebted for this anecdote, adds, that the unfortunate minstrel was beaten almost to death, in consequence of this singular convention.

The khalifs, and other princes of the East, appear to have had their bards, as well as the nations of the North, and the ancient Greeks. There are bards, too, in the Ladrone islands, and among other savage tribes, according to the testimony of different voyagers. Sir John Mandeville, who travelled into the Levant in 1340, relates, that when the Emperor of Cathay, or the grand Khan of Tartary, is at table, with the great men of his court, no one is courageous enough to address him except his minstrels, whose office it is to amuse him. The same traveller adds, that these musicians of the court are considered as officers of distinguished rank. Leo Africanus also makes mention of poets of the court whom he found at Bagdad about the year 990. The institution of bards, therefore, may be said to have prevailed in almost every country of the world.

Though we may presume, that the ancient Britons of the southern parts of our island had originally as fine a taste and genius for poetry as those of the north, yet few or none of their poetical compositions have been preserved, or descended to our own times. This is to be accounted for by the repeated conquests to which this part of our island was subjected by the Romans, Saxons and Normans. But in the mountains of Wales, and of Scotland, where the aboriginal Celts were permitted to retain undisturbed possession of their territory, the native taste for minstrelsy flourished without interruption; and gave birth to numerous productions, which time has spared even to the present day. Nennius who wrote in the ninth century, in the reign of Prince Mervya, makes honourable mention of several of the Cambrian bards. He says, that Talhairan was famous for his verses; as also, Ancurin, Taliessin, Llywarch-hen, and Chian, who flourished in the sixth century. Of these bards, the compositions of three are still extant; viz. Ancurin, Taliessin, and Llywarch-hen. The minstrels of Scotland were not less celebrated in their day, insomuch, that it stamped reputation upon a proficient in this art to say, "that he came out of the *North country*." A great number of beautiful ballads, which we may reasonably conclude to have been the production of these ancient poets, have descended to our times; but, in most cases, the name of the poet has perished. To this, however, there is one very illustrious exception, in the case of the poems ascribed to Ossian, the son of Fingal, who is said to have reigned over a district of the Highlands of Scotland, in the second or third century. If we admit these poems to be genuine, or to have received but a few modern additions and embellishments, they are calculated to give us a very exalted idea of the powers and conceptions of the ancient bards. It is not in this place that we propose to discuss the much agitated question, of the authenticity of these poems; but there is one remark upon the subject, made by Warton, which may, without impropriety, be here introduced. "Notwithstanding," says that author, "the difference between the Ge-

thic and the Celtic rituals, the poems of Ossian contain many visible vestiges of Scandinavian superstition. The allusions in these poems to spirits who preside over the different parts, and direct the various operations of nature; who send storms over the deep, and rejoice in the shrieks of the shipwrecked mariners; who call down lightning to blast the forest, or cleave the rock, and diffuse irresistible pestilence among the people, beautifully conducted and heightened under the skillful hand of a master bard, entirely correspond with the Runic system, and breathe the spirit of its poetry." *Hist. of Eng. Poetry*, vol. i. diss. 1.

As letters have become generally diffused, the institution of bardism has sunk in dignity, and become corrupted; the exercise of this profession having become less necessary or important. It is, however, but a very few years since the Highland chieftains ceased to have family bards; and there are still respectable remains of this institution in Ireland and in Wales. After the reign of Henry VII. the British bards seem to have degenerated into troops of strolling minstrels and players, disgraced by the meanness of their conduct, and the licence of their manners; insomuch, that it was found necessary to enact laws, in order to restrain their irregularities. A curious statute of Queen Elizabeth, of the year 1567, shews the degraded condition in which the bards were at that period. It premises, that, having found that a number of pretended minstrels, rhymers, and *bards*, are in the practice of molesting the inhabitants of Wales, and hindering the expert minstrels, rhymers, and musicians, from executing their profession, and improving it; willing, therefore, to rectify this abuse, and knowing that Sir William Mostyn, and his ancestors, have enjoyed the gift of poetry, and of playing on the silver harp; therefore, we enjoin you, Squire Beoley, Squire Griffith, Ellis Price, and Sir William Mostyn, to assemble on the first Monday after the feast of Trinity; to choose out the best minstrels of the principality of Wales, and to remit the others to till the ground, or to exercise necessary trades," &c.

In proportion as these minstrels lost their respectability and consideration, their compositions sunk in merit, and became as degraded as their persons or their manners. See Evans *de Bardis*. Warton's *Hist. of Eng. Poetry*. Jones' *Relics of the Welsh Bards*. Suard's *Mélanges de Littér.* vol. ii. (m)

BAREGE, or **BARREGE**, a village in France, in the department of the Higher Pyrenees, celebrated for its thermal waters. The temperatures of the four hot springs at Barege differ considerably from each other. The lowest is 73° of Fahrenheit, and the highest about 120°. These waters contain sulphuretted hydrogen, united to a small quantity of soda, a little common salt, and a small quantity of siliny bituminous matter. The specific gravity of the water is a little greater than that of distilled water. In disorders of the stomach, in affections of the urinary organs, and in the resolution of indolent tumours, the waters of Barege have been found of great advantage. The waters are carried to a great distance, and preserved for a long time, though not without losing some of their medical virtues. East Long. 0° 3' 30", North Lat. 42° 53'. See Saunders on *Mineral Waters*, and Rutt's *Methodical Synopsis of Mineral Waters*. (j)

BAREITH, **BAREUTH**, or **BAYREUTH**, is the capital of the ancient margraviate of Bareith, a principality in the circle of Franconia. It is situated between the

three rivers Mein, Mistelbach, and Seudeibach, on the frontiers of the new kingdom of Bavaria. The margraviate of Bareith was annexed to the kingdom of Prussia in 1782, and in the year 1801 it supported a population of 205,440. The town of Bareith, which presents nothing interesting to the eye of a traveller, was formerly the seat of numerous manufactures. Population 10,000. East Long. 11° 50', North Lat. 49° 55'. See Keyser's *Travels*, vol. iv. let. xc. 345; and Pouchet's *Dict. de la Geog. Commerç.* (π)

BARI, the **BARIVM** of the ancients, is a sea-port town of Naples, and capital of the province of Bari. The inhabitants employ themselves partly in fishing, and in the manufacture of glass, linens, and cottons. The province, which contains about 695,273 English acres, and a population of 281,048, produces corn, wine, oil, cotton, saffron, and fruits. According to Chantreaux, the population of the town is 30,000; but the estimation of Swinburne, who makes it only 6000, is probably more correct. East Long. 16° 52', North Lat. 41° 15'. See Swinburne's *Travels*, vol. ii. p. l. (j)

BARILLA, the name under which the impure carbonate of soda is imported from the coasts of Spain and other parts of the Mediterranean. See **SODA**. (π)

BARK. See **TANNING**.

BARK, **PERUVIAN**. See **MATERIA MEDICA**.

BARKING, a market-town of England, in the county of Essex, situated on the small river Rhodding, and on a creek that leads to the Thames. The chief inhabitants of the town are fishermen, who contribute to the supply of the London fish-market. At a short distance from the town, towards Dagenham, stands an old house, where the gunpowder plot is said to have been hatched. Population, 2182. Number of houses, 419. See Lyson's *Environs of London*, and Morant's *History of Essex*. (π)

BARLESIA, a genus of plants of the class Didynamia, and order Angiosperma. See **BOTANY**. (π)

BARLETTA, a sea-port town of Naples, in the province of Bari, whose ruinous exterior, and thin population, form a striking contrast with its interior magnificence. The houses are large and lofty, and the streets spacious and well paved. The antique granite columns of the cathedral, and the colossal statue in the market-place, which is seventeen feet three inches high, and is supposed to represent the emperor Heraclius, are among the principal curiosities of the town. The harbour, which is commanded by the citadel, consists of several irregular piers, but affords no shelter for shipping. The exports of the town are corn, almonds, salt, and liquorice, which grows in the swamps without cultivation. East Long. 16° 20', North Lat. 41° 19'. See Swinburne's *Travels*, vol. i. p. 275. (π)

BARLEY. See **AGRICULTURE Index**.

BARLEY MILL, the name of a machine for taking the husks from barley.

A barley mill of the most improved construction is represented in Figure 1. of Plate LIII. The water wheel A is eighteen feet six inches diameter, and carries fifty buckets, each of which is three feet three inches wide. On the water shaft B, that carries the water wheel, is fixed the spur wheel C, which is eighteen feet diameter, reckoning from the pitch stroke, and has 340 teeth. The spur wheel C impels the pinion D of thirty-two teeth and one foot 8.4 inches diameter, fixed upon one extremity of the shaft E, while the other extremity carries the wheel F of 150 cogs and seven feet 11.45 inches diameter to the pitch stroke

The wheel F drives the pinion G, fixed on the stone spindle H, and having a diameter of four feet six inches. The spindle H carries the millstone I, which is four feet six inches in diameter, and one foot five inches thick, and which performs 280 revolutions in a minute.

The wheel K, of fifty teeth and two feet diameter, impels the wheel L of the same number of teeth and diameter, which is fixed upon the spindle R. On the spindle R is a conical place, upon which the pinion M of twenty-five teeth and one foot diameter, is fixed by means of a brass bush fitted into the centre of the pinion, and then bored exactly to fit the cone in the spindle R. Below the base of the cone is a brass ring 3, to keep the pinion M firm upon the cone, by means of four screw-bolts, which bring the pinion firmer to the base of the cone. On the other side of the pinion are two projections I, I, commonly called snugs, which take into similar projections on the end of the catch 2, 5. This catch slides along the spindle R by moving the lever N, but goes round with the spindle by means of two tongues fixed on the opposite sides of the spindle, one of which is partly visible at 4 in the Figure. Two grooves are cut on the inside of the catch, to admit the tongues, in order to carry the catch round with the spindle. The wheel NO, having 102 teeth, and a diameter of four feet $1\frac{1}{2}$ inches to the pitch stroke, is screwed to the side of the hoops or cases that inclose the stone. These hoops, a section of which is represented by *a, b, c, d*, are made in two parts, and screwed together by four bolts 6, 6, 6, 6. They are lined with milled iron, pierced into small holes, in order to permit the escape of the dust, and prevent the barley from being carried along by means of the mill-stone.

When the hoops are turned round by the wheels already described, they are supported and kept clear of the stone by the collars *h* and *i*. The collar *h* is larger than *i*, in order to give room to the spout PT to fill the hoops with barley. This is effected by a thin plate of iron *k*, about an inch larger in diameter than the inside of the collar, which is kept close to the side of the collar next the stone by the staple *l* on each side of the stone spindle. The other end of it is kept fast by the cover of the pillow block *m*. In the plate *k*, a hole is cut for the end of the spout PT. When the barley is made, the hoops are stopped by putting the lever N towards *f*: a small sluice which is upon the side of the hoops, as at *a, b*, is then opened, and the made barley is allowed to run off into the trough Q. When the hoops are thus emptied, the sluice is shut, and the lever N is brought to *g*. By this means the wheel M engages with the spindle R, by the catch 2, 5, and the sluice X being opened, the hoops are filled with fresh barley. (J. A.)

BARLOW, THOMAS, was born at Langhill, in Westmoreland, in the year 1607; and was descended from the ancient family of Barlow-Moore in Lancashire. He received the first elements of his education at the free school of Appleby; and, in the sixteenth year of his age, removed to Queen's College in Oxford, of which he was chosen a fellow in 1633. Two years afterwards, he was appointed metaphysical reader in the university; and his lectures were published in 1637, for the use of the students. In 1652, he was elected head-keeper of the Bodleian Library; and, about the same time, was appointed lecturer of Church-hill, near Bedford. In 1657, he was chosen provost of his college; and, after the restoration of Charles II. was nominated

one of the commissioners, for reinstating the members who had been ejected by the parliament in 1648. In 1660, he was admitted Margaret professor of divinity; in the following year was elected archdeacon of Oxford; and in 1675, became bishop of Lincoln. He died at Bugden, in Huntingdonshire, in 1691, in the 85th year of his age. He bequeathed his books partly to the Bodleian Library, and partly to Queen's College in Oxford, and all his manuscripts of his own composition to his two domestic chaplains, William Offley, and Henry Brougham, with a particular request, that they should not be made public. The principal of his works that have been published, are his *Metaphysical Lectures*, a *Treatise on Toleration*, the *Gunpowder Treason*, *Advice to a Young Divine*, *Miscellaneous Cases of Conscience*, *Genuine Remains*, a variety of letters and pamphlets, but particularly a number of powerful attacks upon the system of popery. Bishop Barlow was a man of the most extensive literary attainments; intimately acquainted with the learned languages; eminently skilled in theology, church history, civil and ecclesiastical law; and thoroughly master of the controversies between the Protestants and Papists. He was entirely addicted to the Aristotelian philosophy, and keenly hostile to those improvements in physical science, which were introduced by the Royal Society. He was a rigid adherent to the sentiments of Calvin, and a devoted admirer of the school divinity. In his episcopal character, he has been justly censured for never appearing in his cathedral and visiting his diocese; and his political conduct during the troublesome period, in which he lived, was of the most timorous and time-serving description. He was possessed, however, of many excellent qualities; was ever ready to befriend the learned of every country and denomination; and displayed more just and liberal sentiments on the subject of toleration than any individual of his time. See *Biog. Britannica*, and *Biog. Dictionary*; Grainger's *Biog. Hist. of England*, vol. iv. (q)

BARMOUTH, a small watering place in the county of Merioneth, in North Wales, situated on a bay of the same name at the mouth of the river Maw, or Avon. The houses of this town are all built on the bottom and on the declivity of a steep hill. At high water the tide forms an estuary on the river about a mile broad; but numerous sand banks render the entrance hazardous. Great quantities of flannel and hose are made here, and no less than 40,000 lbs. of the former, and 10,000 lbs. of the latter, were exported from Barmouth in one year. See Pennant's *Tour in Wales*; and Bingley's *Tour round North Wales*. (j)

BARNADESIA, a genus of plants of the class Syn-
genesia, and order Polygamia Equalis. See BOTANY.
(zv)

BARNARD CASTLE, a neat and well built town of England, in the county of Durham, situated on the river Tees, and deriving its name from the magnificent castle built here about the year 1178, by Bernard Baliol, upon the summit of a high rock. This town was formerly celebrated for the manufactory of white leather breeches, and for tannies or Scotch camblets. A number of weavers are still employed in making camblets, and the stocking trade is carried on to a considerable extent. Number of houses, 304. Population 2966, of which 465 were returned as employed in trade. See Hutchin-
son's *History of Durham*, vol. iii. (q)

BARNAUL, a town of Siberia, situated in the go-
M m 2

vernment of Kolyvan, on the west side of the Oby, and famous for its silver and copper mines, in which gold is also found. These mines belong to the crown, and are wrought by 48,000 boors, beside the regular miners. About 686 pood, 16 pounds, and 49 solotniks of pure gold, was produced from these mines from 1745 to 1780. (j)

BARNES, JOSHUA, was the son of a tradesman in London, where he was born in the year 1654. He received his grammatical education at Christ's Hospital, and was admitted into Emmanuel College at Cambridge in 1671. He was elected a fellow in 1678; took the degree of bachelor in divinity in 1688; and in 1695 was chosen Greek professor in that university. A Mrs Mason, a widow of Hemmingford, near St Ives, became a great admirer of his learning; and intimated her purpose of leaving him an annuity of 100*l*. "Upon this hint he spake," and secured the widow herself, with a jointure of 200*l*. per annum. He lived about 12 years after his marriage, and died on the 3d of August, 1712. He was buried at Hemmingford, where his widow erected a monument to his memory, with a Latin inscription, and the following anacreontic lines :

Βαρνησιος δ' ἄπαντα
 Νίκησε πολυτεχνης,
 Λογογραφῶν φεριστος,
 Ἄνθος τε των Ἀοιδῶν.
 Των Ἱστοριων μεριστος.
 Και Ρητοριων ἀριστος,
 Και Μαντεων βαβιστος
 Βρεταννικης ἀρεθης.

Which are also thus rendered into English .

Kind Barnes, adorn'd by every muse,
 Each Greek in his own art outdoes ;
 No orator was ever greater,
 No poet ever chanted sweeter.
 He excell'd in Grammar mystery,
 And the Black Prince of history :
 And a divine the most profound,
 That ever trod on English ground.

The learning of Barnes was very extensive, and his pen remarkably ready and prolific. His principal publications were, a volume of Latin and English poems, most of which were composed during his attendance at Christ's Hospital, and before he had completed the 17th year of his age ; a poetical paraphrase of the book of Esther in Greek verse, with a Latin translation and Greek notes ; a History of Edward III., in which he imitates the ancient historians, and puts long elaborate speeches into the mouths of the principal personages ; all the works of Euripides, with a preliminary dissertation on the life and writings of that poet ; the works of Anacreon, with a Latin translation and notes, a life of the poet, and a dissertation on lyric poetry, all dedicated rather preposterously to the Duke of Marlborough ; Homer, with various tracts and dissertations, and a long English poem, in which he ascribes the Iliad and Odyssey to the pen of Solomon, with a view, it has been suspected, to induce his wife to assist the more willingly in defraying the expense of the publication. He wrote a great number of other pieces, which were never published ; and which consisted chiefly of Greek and Latin verses on different subjects ; the lives of Pindar, Sopho-

cles, Theocritus, and the Black Prince ; an ecclesiastical history from the beginning of the world ; sermons, and orations, and critical notes on sacred scripture. He expended much money, and involved himself in considerable difficulties, by the publication of his critical works, few of which produced him much fame or profit in return.

Barnes is admitted to have surpassed most men in the extent of his literary knowledge, to have been full of words, and to have composed in Greek and Latin with wonderful facility ; but he wrote with little elegance, and is frequently very deficient in critical judgment. He was so continually quoting from the Greek classics, that he generally went by the name of Greek Barnes. He neither valued nor understood the English language much ; and was so little acquainted with the usages of his own country, that it has often been said, he would have been more at home in Athens than in London. He had several enemies, or rather rivals in his literary career, some of whom really envied his acquirements, and unjustly slighted his performances ; while others only despised his vanity, or were provoked by the virulence of his censures. He was so remarkable for the compass and quickness of his memory, while his judgment was accounted frequently very deficient, that it has been proposed to add to his epitaph, what Menage said of Pierre Montmaur,

*Hic jacet Joshua Barnes
 Felicissima memoria
 Expectans judicium.*

But, with all his errors as a critic, he will always be respected by the lovers of Anacreon, Euripides, and Homer ; while his pedantry as a scholar was counterbalanced by the many excellent qualities, which he possessed as a man. He was ever liberal of his money to serve his friends ; and has been known, in the warmth of his charity, to give the coat from his back to a ragged beggar. It is also recorded of him, that he always carried about with him a small pocket bible, which, at his leisure hours, he read over 121 times in the course of his life. See *Biog. Britannica. Biog. Dictionary. Granger's Biog. Hist. of England. Monthly Review*, vol. xiv. (g)

BARNSLEY, a small manufacturing town of England, situated on the side of a hill in the West Riding of Yorkshire. A great number of forges are perpetually employed in manufacturing iron wire, nails, and hardware. There are also several manufactures of linen, cloth, and check, and one for bottles of black glass. The country abounds with coal, stone, timber, and iron ore. Number of houses 710. Population 3606, of whom 1832 were returned as employed in trade. The trade and population of this town have been much increased since its connection with Wakefield and Rotherham, by the canal navigations, and by the rivers Dearne and Dove. (j)

BARNSTAPLE, a seaport town of England, in the county of Devon, situated in a fine vale on the eastern bank of the river Taw, over which there is a stone bridge of 16 arches. On account of the shallowness of its harbour, which does not admit vessels of more than 200 tons, a great part of its woollen trade was transferred to Biddeford. Manufactures of baize, however, silk stockings, and waistcoat pieces, still employ its inhabi-

tants. Number of houses 619. Population 3178, of whom 578 were returned as employed in trade. See Oldfield's *History of the Boroughs*. (j)

BAROACH, BROACH, BAROKIA, or BARUK, the *Barygaza* of the ancients, a town of Hindostan, in the province of Guzerat, situated on a rising ground surrounded with water, on the river Nerbuddah, near the place where it falls into the Gulf of Cambay. A fac-

tory was established here in 1616 by the English; and in 1683 it had flourished to such a degree, that no less than 55,000 pieces of baftas, &c. of different kinds, manufactured in the neighbourhood, and superior to those of Bengal, were shipped for England. Agates, found in the mountains near Brampour, also form one of the articles of its trade. East Longitude $72^{\circ} 54'$, North Latitude $21^{\circ} 48'$. (j)

BAROMETER.

BAROMETER (compounded of *βαρος* weight, and *μετρον* measure,) is an instrument for determining the weight of the air, and the variations of its pressure in different circumstances.* As every change in the weight of that fluid is accompanied with corresponding changes of density, and consequently of its disposition to absorb or deposit moisture, the barometer is also employed to point out the probable changes of weather; hence it is not unfrequently called a *weather-glass*. (See METEOROLOGY.) Another purpose, scarcely less important, to which this instrument has lately been much applied, is the measurement of accessible heights; and the results obtained by means of it approach so near to perfect accuracy, when all circumstances are properly estimated, that this method of determining the heights of mountains is, in many cases, even preferable to the geometrical methods. (See HEIGHTS.) It also appears from the observations of Captain Flinders, that the barometer may be of the most essential service at sea, not only to foretell changes of weather, but also to indicate the vicinity of land. (See WINDS.) These important properties entitle this instrument to a considerable share of our attention.

Before the discovery of the weight of the air, the barometer was entirely unknown; and indeed it was the discovery of that fact, which led to the invention of the instrument. The ancients ascribed to the *horror of a vacuum* all the effects which arise from atmospherical pressure. This explanation, absurd as it may now seem, was admitted even by Galileo; and the ingenuity of a Pascal and a Boyle was scarcely sufficient to point out its futility, and banish it from the established principles of philosophy. The influence of occult qualities, was, in all difficult cases, assumed to explain the phenomena of nature, and it was less inconsistent with their prejudices to ascribe the effects of the weight of the air to an invisible agent, or an unknown principle, than to the operation of a fluid, which they thought was so obviously destitute of all weight. It was accordingly considered as an indisputable fact, that the ascent of water in pumps, and other similar effects of atmospherical pressure, were owing to the horror which nature has for a vacuum. This opinion was universally received till the superintendent of the water works of the Grand Duke of Tuscany, wishing to raise water, by means of a pump, to a considerable height, was surprised to find that the water would not rise higher than 32 or 33 feet. After he had

ascertained that this could not be ascribed to any defect in the construction of the pump, he mentioned the circumstance to Galileo, and requested him to give him an explanation of the cause of this anomaly. Galileo, either not questioning the justness of the opinion which then prevailed, or being unable to assign any other that was more plausible, replied, "That the water was raised to the height of 32 feet on account of the horror which nature has for a vacuum; but that the horror was limited in its effects, and ceased to operate above the height of 32 feet!" This explanation, so unworthy of the name of Galileo, would be totally undeserving of credit, did we not know the authority that an error which has prevailed for twenty centuries could have over the human mind. It appears, however, that he was by no means satisfied with the explanation which he had given, and that he immediately began to suspect the agency of some external cause; but his death, which happened soon after, prevented him from bringing his thoughts to maturity. His disciple Torricelli, to whom it is supposed he had mentioned his ideas on the subject, was more successful in his explanation. He suspected that the weight of the water was one of the elements which ought to be taken into consideration in investigating the cause of the ascent of that fluid in pumps, and that it was probably counterbalanced by the weight of something external pressing upon the surface below. To put this conjecture to the test of experiment, he took a glass tube about four feet long, (as A B, Plate LIII. Fig. 2.) hermetically sealed at one end A, and open at the other. Having filled it with mercury, he shut the open end with his finger; he then inverted the tube, and introduced the open end of it under the surface of a small quantity of mercury in a bason. Lastly, he placed the tube in a vertical position, and on withdrawing his finger, he observed that a part of the mercury descended in the tube, and that the rest of it was supported at the height of $27\frac{1}{2}$ inches above the level of the mercury in the bason. By varying the experiment, he found that, in all cases, the mercury was supported at a perpendicular height above its surface in the bason, equal to about the 14th part of the height of the water in the pumps. He therefore inferred, that the mercury in the tube, and the water in the pump, exerted equal pressures on the same base, their altitudes being inversely as their specific gravities, and that the weight of the column in either case was counteracted by some fixed and determinate force. This force he supposed was the weight of the air.

This explanation, however natural and obvious it may now seem, was by no means so readily admitted as might have been expected from its extreme plausibility. The principle of the horror of a vacuum was too firmly believed to yield at once to the simplicity of truth. A

* As an increase in the elasticity will compensate for a deficiency of the density of the air, and maintain the mercury at the same height; the barometer cannot, with strict propriety, be denominated "an instrument for determining the weight of the air." HEMMEL, JUN.

tempts were accordingly made to reconcile the experiments of the pumps and the tube of Torricelli, with that absurd opinion. It was maintained, that a subtle fluid or ærial spirit, was evaporated from the surface of the water and the mercury, which filled the upper part of the tube, and left only as much activity to the horror of a vacuum as was sufficient to sustain the column of those fluids.

When Pascal, who was then at Rouen, was informed of the experiments of the Italian philosophers, he was anxious to repeat them; and soon after obtained the same results. It does not appear, however, that he was aware of the conclusions which Torricelli had drawn; but, by reflecting on the nature of the experiment, he was soon convinced that the principle of the horror of a vacuum was altogether gratuitous and improbable, and that the suspension of the mercury was owing to some other cause. To place the matter beyond all dispute, he employed tubes of glass 40 feet long, and having filled one of them with water, and another with wine, he inverted them respectively in basons of these fluids, after the manner of the experiment of Torricelli. The water remained suspended at the height of 31 feet 1 inch and 4 lines; and the wine, at the height of 33 feet 3 inches. These experiments were performed at Rouen in 1646, in presence of several men of science, all of whom were attached to the old opinions. The conviction which they produced on their minds was complete, and they immediately embraced the new doctrines. Pascal published an account of the experiments the following year, in a work entitled *Expériences nouvelles touchant le vide*. This work was severely attacked, particularly by P. Noel, a Jesuit, who was then rector of the college of Paris. All the prejudices of a bad philosophy, and all the virulence of error, were summoned to the attack; and Pascal had the mortification to find, that many were still disposed to question the conclusions which he had drawn from his experiments.

At length an experiment occurred to him which he saw would for ever silence the objections of his opponents, and establish his opinion beyond the possibility of controversy. If the mercury in the Torricellian tube, said he, is supported by the pressure of the air, it ought to stand higher or lower according to the length of the columns of the atmosphere at the place of observation; on the contrary, if the weight of the air has no connection with the height of the mercury, the mercury ought to stand at the same elevation, at all heights in the atmosphere. He therefore prepared to make the experiment on a large scale; and in order that the difference between the heights of the mercury at the places of observation might be an appreciable quantity, he pitched upon the mountain Puy-de-dome, in the neighbourhood of Clermont, as well adapted to his purpose. Being at that time in Paris, he wrote to his brother-in-law Perrier, a man of distinguished talents, who was then going to Clermont, requesting him to perform the experiment on his arrival. Various circumstances prevented the experiment being tried till the 19th of Sept. 1648, when it was performed with equal accuracy and skill. The result coincided with the expectations of Pascal. As they ascended the side of the mountain, the mercury gradually subsided in the Torricellian tube; and when they reached the summit, it stood 3 inches $1\frac{1}{2}$ lines lower than at the bottom. The experiment was repeated on different sides of the mountain, and always with a similar result.

Pascal no sooner was informed of the details of these experiments, than he repeated them on a small scale at the top and bottom of the steeple of St Jacques-la-Boucherie; and he observed a corresponding difference between the heights of the mercurial columns. There now remained no longer any pretext of ascribing the elevation of the mercury in the tube to the horror of a vacuum; for, it would have been absurd to pretend that nature had a greater abhorrence of a vacuum in a valley, than on the top of a mountain; and accordingly all those who were sincerely desirous of discovering the real cause of the phenomenon in question, admitted the conclusions of Pascal concerning the weight of the air, and applauded the simple and decisive method which he had taken to demonstrate its influence. On the whole, the history of this research affords a signal instance of the slow and gradual progress of human knowledge: Galileo proved that the air was possessed of weight; Torricelli conjectured that this fluid caused the ascent of water in pumps, as well as the suspension of the mercury in the tube which bears his name; and Pascal converted this conjecture into a demonstration.

But the triumph of Pascal was too complete not to excite afresh the malignity of his enemies: Descartes, among others, attempted to deprive him of the honour of the discovery of the pressure of the air; and in a letter which he wrote to M. Carevi, dated June 11, 1649, accuses Pascal of a want of candour, and asserts that he first suggested to him the experiment of Puy-de-dome. Pascal, on the other hand, maintains, in the most solemn manner, that the experiment was entirely his own, and that he never received the smallest hint of it from any person. It would be improper to enter here into the merits of the dispute; but it appears to us, that the pretensions of Descartes are altogether groundless, and that the discovery of atmospherical pressure is due to Pascal alone.

It is obvious, from the experiment of Puy-de-dome, that the Torricellian tube, if properly graduated, may be employed to measure the heights of mountains; a purpose, we already mentioned, to which it is now frequently applied. Boyle suggested this application of it in 1665.

After it was ascertained, that the weight of the air was the true cause of the suspension of the mercury in the tube of Torricelli, Perrier continued to make daily observations with it, from the beginning of 1649 to the end of March 1651. One of his friends at Paris, and Descartes, who was then at Stockholm, made similar observations during the same period, and they found, that the column of mercury varied in length, according to the temperature, the winds, the moisture, and other circumstances connected with the state of the atmosphere. Thus the tube of Torricelli became an instrument, not only for shewing the weight of the air, but for pointing out the changes of weather which happen in consequence of variations in the weights of the atmospherical columns. Some pretend that Otto de Guericke first proposed to employ the barometer as a weather-glass; but this idea, so obvious, was a natural consequence of the observations of Perrier and Descartes, and must have occurred at a very early period to these philosophers. Boyle made many meteorological observations with it in 1666; and he was also at great pains to refute a hypothesis advanced by Linus, concerning the cause of the elevation of the mercury in the Torricellian tube. This hypothesis, which prevailed for some

time, was called the *Funicular hypothesis*: it assumed, that the mercury was supported by an invisible rope of the same metallic fluid; an opinion so extremely absurd, that, in the present state of science, we have some difficulty in believing that it was ever maintained, or that it should have been deemed worthy of a grave refutation.

The experiment of Torricelli was so simple, and yet so easy to be exhibited under a variety of forms, that a great number of barometers were soon proposed, either with a view of rendering them more correct, or enlarging the extent of the barometrical scale. Before we proceed to give particular descriptions of these instruments, and of the various attempts which have been made to increase their accuracy and sensibility, it may not be improper to make some previous remarks applicable to barometers in general.

The tubes intended for barometers ought to be sealed hermetically at both ends, immediately after they are made at the glass-house, and to be kept in that state till they are to be fitted up. Without this precaution, they are apt to be sullied with dust, moisture, and other impurities, which it is almost impossible afterwards to remove, on account of the smallness of their diameters. When they are opened, which may be done with a file, care should be taken not to breathe into them, or to wash them with spirit of wine, or any other fluid; experience having proved, that in tubes so treated, the mercury always stands a little below its proper level. This is, no doubt, owing to the adhesion of a little of the spirit of wine to the sides of the tube, which being afterwards converted into vapour, renders the vacuum above the mercury imperfect. If any cleaning is necessary, it may be done with a fine linen rag, that has previously been well dried.

The tubes ought to be as perfectly cylindrical as possible, though, in some cases, this is not absolutely necessary. They should be about 53 inches in length, and the diameter of their bore should be at least 2 or 2½ lines, otherwise the friction, and capillary action, will be apt to affect the free motion of the mercury. The glass should not be very thick, as it is apt, in that case, to break, when the mercury is boiled in the tube: half a line is sufficient.

The mercury ought to be perfectly pure, and free from all foreign metals. The best is what has been recently revived from cinnabar; the common mercury of the shops being often adulterated intentionally with tin, lead, and bismuth, stands at various heights in the tube, according to the nature and quantity of the foreign substances with which it is amalgamated.

The different mechanical methods which have been proposed for purifying mercury, are, for the most part, ineffectual; we would, therefore, recommend the revivification of the metal from cinnabar, for nice barometers, as being least liable to uncertainty. For this purpose take a pound of cinnabar, and reduce it to powder; mix it well with five or six ounces of iron, or steel filings; and having put the mixture into an iron retort, expose the whole to the heat of a reverberatory furnace; the mercury will soon pass over in a state of great purity; and may be obtained, by adapting to the retort an earthen receiver which has been previously half filled with water.

Before being introduced into the tube, the mercury ought to be well heated, or even boiled in a glazed earthen pipkin, in order to drive off any moisture which

may adhere to it; but this will be unnecessary, if the mercury has been recently revived.

The mercury ought likewise to be boiled in the tube, to expel any air or moisture which may still remain attached to it, or to the inside of the tube. This is done in the following manner: Pour as much mercury into the tube as will make it stand to the height of three or four inches; and introduce a long wire of iron to stir it during the act of boiling.* Expose the mercury in the tube gradually to the heat of a chafing dish of burning charcoal; and when it begins to boil, stir it gently with the iron wire to facilitate the disengagement of the bubbles of the air. When the first portion of the mercury has been sufficiently boiled, and all the air extricated, remove the tube from the chafing dish, and allow the whole to cool, taking care not to bring it into contact with any cold substance. Introduce an equal quantity of mercury, and treat it in the same manner, withdrawing the wire a little, so that it may not reach below the upper part of the mercury already freed from air. The chafing dish must also be placed immediately under the mercury which has been last poured in. Repeat the same process with each successive portion of mercury till the tube is filled, always applying the heat very cautiously; and be equally careful in allowing it to cool, before a fresh portion of mercury is poured in.†

* A more infallible method to break a tube could not be devised, than to introduce a wire into it. A horse hair, if pushed down a narrow tube, so as to make its end rub the glass, will cause it to break on the application of a higher temperature; even the heat of the hand will be sufficient in cold weather. HEMBEL, jun.

† The process above described is so very exceptionable, to take no notice of the delays, arising from suffering the mercury to cool every time that more is to be added, that we cannot refrain from offering to our readers, the result of our experience in constructing the above instrument.

To construct a good barometer, a chafing dish should be procured, about four inches high and as many square; having an opening in one of the sides, about two inches long and one wide. On the floor of the room should be spread a blanket to collect the mercury which may be dropped, over the middle of which, a table should be placed with the chafing dish near one of its corners, having the opened side next to the edge of the same. The bars of the grate should be half an inch apart, to permit the mercury to fall on the blanket; otherwise the operator might be salivated by the volatilized mercury.

The tube must not be filled with mercury beyond six inches from the aperture; as, during the boiling, the column of mercury is often separated several inches by the rarefied air, and if the heat is suddenly increased, a column of twenty inches or more, will be entirely projected from the tube. To conduct the process successfully, requires a dexterity in the manipulation, which can only be acquired by practice and attention; for, to the most experienced, it is always a difficult undertaking, from the facility with which the tubes may be broken. Hence, to prevent disappointment, the operator should be provided with several.

To commence the boiling, the chafing dish should be filled with fully ignited coals, and, about six inches from the sealed end of the tube, gradually heated, by moving

It sometimes happens, when the tube is carefully inverted, as in the Torricellian experiment, that the mer-

cury, after being completely freed from air, in the way we have described, remains suspended in the upper part

the tube backward and forward in an inclined position, at a small distance above their flame; turning it round at the same time.

In proportion as the mercury becomes heated, the tube may be cautiously brought nearer to the coals, and when the mercury is near boiling, its surface will acquire an ash-grey colour, from innumerable minute globules of air, which on an increase of heat, unite into larger. If the tube be now held, at an angle of 45 or 50 degrees, the globules will ascend in the tube. As soon as that is observed, the tube should be held nearly vertical, and the sealed end brought nearer to the coals, the mercury will soon boil about one inch in length; it should be kept *gently* boiling for a minute or two, the operator carefully avoiding a sudden increase of heat, which would either project the mercury from the tube, or separate the column several inches—the interval being occupied by highly rarefied air, which, on the least diminution of temperature is condensed, and the pressure of the incumbent atmosphere forces the mercury down with a momentum, which breaks the tube into innumerable pieces. During the boiling of the mercury, it is advisable, occasionally to turn the tube round, by which means it is more uniformly heated, and the air easier expelled, than if one side be kept constantly next the coals. Indeed, if the tube is held constantly in one position, globules of air will adhere to the upper side of the same, and no agitation, which can be given to the mercury by boiling, will be capable of detaching them.

When the air is sufficiently expelled from the sealed end, it will be necessary to heat 5 or 6 inches of the mercury further up, and when the minute globules unite into larger and rise in the tube, then the mercury must be made to boil about one inch from the sealed end, always observing with particular attention, that a portion of the mercury which has undergone ebullition, should be included in that afterwards to be boiled: otherwise, the air cannot be completely expelled. The boiling of the remaining mercury must be conducted in the same successive manner, particularly holding in mind, that, previous to making the mercury boil at any part, 5 or 6 inches of the incumbent mercury, must be heated nearly to the boiling point, as before mentioned.

At the commencement of the boiling, the tube can only be held with one hand; it will, however, be indispensable to use the other, as soon as the tube projects through the opening in the side of the chafing dish. Should the heated mercury render it painful to the hand to support, a thick leather glove may be used, or a large cork having a cavity about the diameter of the tube. This support should not be deferred one moment after it can be applied, as, during the ebullition of the mercury, the tube is so strongly agitated, that it is difficult to prevent its striking against the edge of the opening, through which the tube must necessarily pass, and thus endanger the safety of the tube.

After all the mercury in the tube is boiled, there will be found on its surface a reddish brown oxide and some moisture, which must be removed, before more mercury is introduced. A considerable part of the moisture may be removed by the feather end of a quill, after which, some soft, old and clean lincn may be rolled round a stick, and introduced into the tube; by turning

the stick round, much of the filth will adhere to it; a fresh piece of lincn should be used as often as the former becomes soiled, after which the lincn may be dipped in strong alkohol, and the tube and surface of mercury repeatedly washed, until they are perfectly clean: the moisture communicated by the alkohol may be expelled, by holding the tube over the ignited coals.

It will now be necessary to introduce as much additional mercury as will fill the tube, to within one inch of the aperture, which must in like manner be boiled; but, as the pressure from the incumbent mercury is inconsiderable, no difficulty will occur. It will however be proper to raise the side of the chafing dish opposite to the opened side, as high as the retaining the coals in the same will permit; by that means, the tube may be held nearly vertical: for, it must be obvious, that, if the tube is now held with much obliquity, the last inch of mercury could not be retained in the tube, particularly during the ebullition of the same. When the boiling of the last addition is completed, the tube may be entirely filled and the air expelled in the best manner which can be effected, by the most gentle boiling or rather simmering of the mercury.

The above is the method by which meteorologists construct their own instruments (the best of those made for sale are not constructed with such care.) Yet, with whatever attention the process may be conducted, a considerable quantity of air will remain, as may be evinced, by reboiling the same tube, even three or four times. Indeed, the total expulsion of the air may be considered impossible, whilst the tube must be held obliquely over the chafing dish, and the whole column of mercury cannot be heated to the boiling temperature at the same time. The sealed end of the tube in particular, will often require more time to expel a single globule of air, than will be necessary to finish boiling the remainder of the mercury. The greater part of the air, it is true, may be readily expelled; but a single globule will remain about one inch from the end, where it is condensed by the colder mercury; and when the mercury there is made to boil, the globule will descend to the sealed end again, with more facility, than it can be made to ascend. The effect appears to be produced by the pressure of the incumbent column of mercury, and the affinity of aggregation with which the particles of mercury cohere, opposing a resistance, which the small quantity of remaining air does not possess sufficient elastic force to overcome. Much however of the difficulty may be removed by heating (nearly to boiling) successively, the whole mercury in the tube previous to boiling; thus, the moisture which the mercury contains, together with a considerable part of the air, will be expelled; and in the subsequent boiling, the remaining air will meet with less resistance in its ascent: it being ascertained by experience, that when a part of the air is expelled by boiling from one part of the tube, the remaining air rises much more freely from the mercury immediately below, when that is afterwards heated to ebullition.

To render the instrument perfect, it appears necessary, that the whole of the mercury in the tube should be heated to ebullition at the same time, and that the tube should be kept vertical during the boiling.

of the tube, and does not assume its proper level, with respect to the pressure of the atmosphere, till the tube

To the following method of obtaining that desirable object, the writer can conceive no other objection, than the expense of the mercury necessary to form the bath. But when it is considered, that with proper care, little of the mercury would be lost; that a bath once constructed would last a number of years; and that all instruments made with it would be of uniform quality (which is not the case with any two made by the present method) the objection, he apprehends, would not prove an insuperable one: as few persons who wish to possess the instrument for accurate observations, would object to a small increase in the price, to obtain one of the most perfect construction.

Let there be procured a cylindrical boiler of cast iron, about 45 inches long, and 3 inches internal diameter, having a shoulder or rim, projecting about 3 inches from the outer circumference, and about 2 inches below the upper or open end of the boiler: this shoulder is intended to support the boiler in the furnace. From the shoulder upwards, the outer circumference of the boiler should be tapered, to admit a distillatory head to be ground on it, which head may be shaped like those used with glass alembics, having a beak or pipe 18 or 20 inches long: or, the head may be semicircular, with a hole in the upper part, into which a bent gun barrel may be rivetted, as is common to other vessels used for distilling mercury. When the boiler is to be used, it should be so placed in a furnace, that the whole body up to the shoulder may be freely exposed to the flame. It is then to be filled with mercury, except about four inches from the top; the tube, being also filled, is to be introduced into the mercurial bath. But, as the tube from its greater levity would rise above the surface of the mercury, it must be kept down, by two iron clips, each having 3 radii and a hole in their middle, to admit the tube to pass freely through. The radii should be sufficiently long, to press against the sides of the boiler, to prevent their rising during the ebullition of the mercury; or, they may be connected by slender iron rods; in that case, the radii of the upper clip may be bent (upward) at right angles, and screws passing through the shoulders may produce the required pressure. One of the clips should be passed so far down the boiler, that the sealed end of the tube may project about one inch below it, the other should be placed about one inch below the surface of the mercury, and the tube kept in its place, by passing an iron wire around the radii of the upper clip and across the orifice of the tube.

The tube being thus secured, the head is to be put on and luted, the orifice of the beak, or pipe, should be immersed barely below the surface of water in a bowl, and the boiling commenced with dry wood, or any combustible which affords a large flame, by which the whole length of the boiler will be heated, and the mercury made to boil in a short time, which will be indicated by the mercury distilling into the water.

A tube boiled for 20 or 30 minutes in the above method, will unquestionably be freed from all the air which can be expelled at the temperature of boiling mercury. The tube being vertical, no other resistance than the pressure of the incumbent mercury, can be opposed to the rising of the air, whilst the uniform temperature of the

has been gently shaken. This fact, which seems to have given great difficulty to Huygens, is certainly owing to the capillary attraction of the tube, and the mutual attraction of the particles of mercury, as it takes place only in tubes of a small bore. To say, that it is owing to the influence of an invisible ethereal fluid, more subtle than air, is no less unphilosophical than the semicircular hypothesis of Linus, or the principle of the horror of a vacuum, particularly when we can assign a cause for it, of whose operation we have many simple and obvious proofs.

The Torricellian experiment exhibits the barometer under the simplest, though not the most convenient form. The tube AB, (Fig. 2. Plate LIII. which is hermetically sealed at A, ought to be about 33 inches in length, and $2\frac{1}{2}$ or 3 lines in diameter of bore. Since the height of the mercury in the tube must be reckoned from the surface of the mercury in the bason, the width of the latter ought to be such, that the elevation or depression of the mercury in the tube may have little effect in changing the level of the mercury in the bason. In the more improved barometers, contrivances, which we shall afterwards explain, have been adopted for preserving the lower surface of the mercury at the same level; but this is obtained sufficiently well for common purposes, by giving the bason a considerable diameter with respect to that of the tube.

The common barometer, represented in Fig. 3, differs but little from the Torricellian tube. Instead of a bason, a small reservoir is usually attached to the lower extremity of the tube, or rather the tube itself is swelled out into a bulby form, as represented at Fig. 4. In this form, however, the instrument is by no means accurate, particularly when the diameter of the bulb, as is usually the case, differs but little from the diameter of the bore of the tube. In order to keep the surface of the mercury in the bason always at the same level, the father of the late Mr George Adams constructed the bason wholly, or in part, of leather, and by means of a screw at the bottom, adjusted the surface of the mercury in it, so as to have it always at the place from which the divisions on the scale commence.

In this country, the lowest station of the mercury is observed to be about 28 inches, and its highest 31 inches above the level of the mercury in the bason: and when the instrument is to remain in a fixed position near the surface of the earth, we may consider the interval between these two points as the range of the barometrical scale. The scale which, consequently, will embrace three inches, may be subdivided into smaller divisions, according to the degree of nicety required. Each inch is commonly divided into ten equal parts; and these are subdivided into hundredths of an inch, by a contrivance called a *vernier* scale. (See *VERNIER*.) By this means the height of the mercury is ascertained, by inspection, to the $\frac{1}{100}$ th of an inch. For nice purposes, the vernier may be made to indicate the $\frac{1}{1000}$ th of an inch.

Besides these lineal divisions, the scale is divided into other points, having a reference to the instrument

mercury, will preserve both air and moisture in an expanded state, until they rise out of the mercurial bath; an advantage, the want of which renders the boiling in the usual manner so difficult, and the instruments so ununiform when compared. HENBEL, jun.

in its capacity of indicating the probable state of the weather. At 31 inches, the highest point of the scale of variation, *set fair* is marked on the one side, and *set frost* on the other. At 30 inches, *fair* is written, in like manner, on the one side, and *frost* on the other; and at half an inch below is written the word *changeable*, which answers both for summer and winter.

The common barometer answers sufficiently well for most purposes, when the observations are made at the same place; but as many of these necessarily imply a change of situation, it soon became an object of importance to construct barometers in such a manner that they might be conveyed from one place to another without much inconvenience or risk. Barometers of this kind, which are called *portable barometers*, are chiefly employed for measuring heights. They have assumed, under the hands of different artists, a variety of forms.

Derham mentions a portable barometer; but as many circumstances connected with the accuracy of the instrument are entirely overlooked in its construction, it does not merit a particular description. (*Phil. Trans.* vol. xx. N^o 236.) The portable barometer consists, in general, of a tube of the usual length, passing through the upper part of a wooden cistern, to which it is glued, and the bottom of which is made of leather. The tube being filled with mercury, which has been previously well purged of air, and placed in a proper position, the superfluous mercury descends into the cistern, and assumes a level in the tube, corresponding to the weight of the external air. The surface of the mercury in the cistern is adjusted to the same level by a screw, which presses more or less against the flexible leather at the bottom, and raises or depresses it at pleasure. From the line of this level, which is called *zero*, the scale commences, and is reckoned upwards to the height of about 32 inches: the actual divisions of the scale begin at about 15 inches. Various methods have been employed for constructing the portable barometer in a manner best suited to carriage, to placing the tube in a vertical position at the time of observation, to ascertaining the surface of the mercury, and to making allowances for the expansion and contraction of the mercury by changes of temperature: but it will be sufficient to describe the instrument in its present most improved form.

Plate LIV. Figures 1, 2, and 3, represent the portable barometer as constructed by Mr Troughton, and first made by him in 1785. The greatest peculiarity in this instrument, according to the opinion of this ingenious and philosophical artist, consists in the excellent manner in which the mercury in the cistern is set to the zero of the scale of inches. For this purpose, a glass cylinder of about 2.5 inches diameter, and as much in length, contains the mercury. An external covering of hollow brass, terminating in a female screw a little above and below the glass, admits male screw pieces, whose ends, well *leathered*,* being pressed hard against

the ends of the glass, prevent the escape of the fluid. Near the upper end of the brass cover are two slits made horizontally, one before, and the other behind, exactly similar and opposite to each other. At bottom is a screw, seen better in the section Fig. 2, which, acting upon the usual leather bag, forces the quicksilver upwards at pleasure, and, by filling every part, renders the instrument portable. But the primary design of this screw is, to furnish the means of adjusting the surface of the mercury in the glass cistern, so as just to shut out the light from passing between it and the upper edges of the slits in the brass cover. This is the mode of adjusting to *zero*; and it follows, that the upper edges of the slits must represent the beginning of the scale of inches. The frame is entirely made of a brass tube, and above the cistern is of about 1.1 inch diameter. The first ten inches of the lower end is occupied by a thermometer, whose bulb, bent inwards, is concealed within the frame. At about three inches higher, it attaches to the stand by a ring, in which the frame turns round with a smooth and steady motion, for the purpose of placing the instrument in the best light for reading off, &c. The actually divided scale commences at about 15 inches above the *zero*, and is continued as high as 33 inches, and, by the usual help of a vernier, is subdivided down to .001 of an inch. A longitudinal slit, from end to end of the divided part, exposes to view the glass tube and mercury within it. The whole of this part consists of two tubes of brass. In the inside of the interior one, slides a cylindrical piece, on which is divided the vernier scale, the index to which is the lower end of the piece. In taking the height of the mercury, this piece is brought down so as just to exclude the light from passing between itself and the spherical surface of the mercury. The screw at top, although but a short one, performs this office in whatever part of the scale the vernier piece may be; for it acts upon the interior long tube, in the inside of which the piece is sustained by friction; and in which it is, on every occasion, to be set by hand nearly. The tripod is altogether similar to what Mr Ramsden used for the same purpose, as far back, perhaps, as the year 1775. It affords, when closed, (PLATE LIV. Fig 4.) a safe and convenient packing-case for the instrument. The structure of the staff-head is curious. The principal part is a circle (Fig. 5.) about .75 of an inch broad, jointed in three pieces: these, although they seem in principle to be incapable of motion, yet, in practice, produce what is fully adequate to the purpose. The three joint-pins extend inwards, so as to pass through a circular rim, which they hold fast: within this rim is hung a similar one by two pivots; and inside the latter, at right angles to the pivots, are fastened two Y's or angles, in which the barometer hangs by its gudgeons. Thus are brought about, in a small compass, the means of extending the legs, of turning the instrument about respecting the tripod, and an universal joint, whereon it readily places itself perpendicular to the horizon.

We shall conclude the account of the portable barometer for the measurement of heights, with the description of one which has lately been constructed by Miller and Adie, uniting the advantages of Troughton's with several important improvements. The general appearance of this instrument, when on its tripod, is nearly the same as that represented in PLATE LIV. Fig. 6. The scale and vernier are the same as those already described; the top of the tube, which forms the

* It is to be regretted, that no method has yet been devised to construct the cistern without a hygrometric substance. When the air is moist, the leather stretches; thus the capacity of the cistern is enlarged, and the mercury falls lower in the tube than it should. On the contrary, when the air is dry, the leather contracts, and the capacity of the cistern being in consequence diminished, the mercury is forced higher up the tube than it otherwise would rise. HERBERT, jun.

frame, is cut open on the opposite side, so as to allow the finger and thumb to lay hold of the head of the adjusting screw, and is continued beyond it about half an inch; this space is occupied by a circular level, by which the instrument is very conveniently placed in a vertical position. The ball of the attached thermometer is made of a piece of the barometer tube about 1.5 inches long, and bent back so as to lie parallel to the tube of the barometer, with which it is nearly in contact. The mercury in both being thus similarly situated, is equally and simultaneously affected by a change of temperature. The cistern is made of two circular pieces of wood, connected together with leather. Two concentric screws work in the bottom of the external brass cover: the outer screw is intended to raise the whole bottom of the cistern, in order to press the mercury quickly to the top of the tube, either for carriage, or to make room for a considerable descent of the mercurial column. The use of the small central screw is to adjust the surface of the mercury to zero, by pressing a small leather bag in the bottom of the cistern, by which the adjustment is performed more steadily than if the whole area were acted upon. In the top of the cistern is inserted a bit of the barometer tube, about half an inch long, surrounded by a hollow cylinder of ivory, terminating in a female screw, which is stopped by a finger screw of ivory, to prevent the escape of the mercury when the instrument is packed up for carriage. The ivory cylinder has an external covering of brass, whose width is equal to the diameter of the tube that forms the frame of the barometer; both the brass and ivory coverings are cut open on the opposite sides, that the surface of the mercury may be seen through the glass tube, and that the line of light betwixt it and the upper edges of the slits in the brass cover, which is the beginning of the scale, may be distinctly cut off. By this method of adjustment, the upper and under surfaces are observed as nearly as possible under similar circumstances, as to inflection of light, attraction, &c. In this construction, the tube being readily accessible, can easily be cleaned when it is soiled by the mercury, which always happens when the surface of the metal is exposed to the action of the air.

On the top of the tripod is a hollow ball and socket; in the centre of the ball is an universal joint, in which the barometer is hung in Y's; it is then set perpendicular by the level on the top. Four finger screws hold the frame of the barometer steady, so as not to be shaken by the wind, or hand, in turning the adjusting screw at the top. When the instrument is placed on uneven ground, so as to require an adjustment beyond the range of the screws, it is brought nearly perpendicular, and to the most advantageous position for observing, by unturning a little the milling forming the upper part of the socket, which must be again pinched. The tube is never removed from the legs of the tripod; to prepare it for carriage, the pivots on which it hangs are lifted out of the Y's, and turned a little to one side; and it is then let down until the pivots, which project from the frame about an inch and a half below the top, rest on the ring at the upper opening of the ball. The legs are then closed on it, and held together by brass rings. A brass cap is then screwed on above the joints of the legs, which protects all the upper parts. Two microscopes, for observing the surfaces of the mercury, pack in the lower part of the legs. PLATE

LIV. Fig. 6. represents the cistern, and the top of the tube.

When the barometer is to be used at sea, some contrivance is necessary to prevent the oscillations of the mercury. Two methods are employed for this purpose: either to prevent, by mechanical means, the vibrations of the instrument itself, or to check the motions of the mercury in the tube by some peculiarity of form. Both methods may also be conjoined.

One of the earliest marine barometers with which we are acquainted was suggested by Dr Hooke. It consisted of two thermometers, or rather of a manometer, (See MANOMETER,) and a thermometer placed together in the same frame. The thermometer was affected only by the warmth of the air; the manometer, acting by the expansion and contraction of an included bubble of air, was affected not only by the warmth, but also by the weight of the air. If the two tubes, therefore, are so graduated as to agree with each other when the air is included, it is evident, that when they afterwards agree, the pressure of the atmosphere must be the same as when the air was included. And in general, if the thermometer be taken as a standard, the difference of ascent or descent in the other will point out the increase or decrease of the weight of the air. At the same time, it ought to be mentioned, that the condensation and rarefaction of the air, on which this instrument is altogether founded, do not depend solely on the weight of the atmosphere, but are greatly influenced by temperature. Hence this instrument cannot, strictly speaking, be called a barometer, but rather a contrivance for pointing out alterations in the state of the air; and as such, according to the observations of Dr Halley, it may be of considerable utility. During his voyage to the South Sea, he had one of these barometers, and "it never failed," says he, "to prognosticate, and give early notice of all the bad weather we had, so that I depended thereon, and made provision accordingly; and from my own experience, I conclude, that a more useful contrivance hath not for this long time been offered for the benefit of navigation." *Phil. Trans.* 1700-1, N^o 269, p. 791.

M. Passemont obviated the effects of the motions of a ship at sea on the barometer, by twisting the middle of the tube into a spiral, consisting of two convolutions; by this contrivance, the impulses which the mercury receives, mutually destroy each other, by acting in opposite directions. The effects of the external and momentary impulses may also be diminished by widening the upper part of the tube where the scale is applied. The oscillations, which would be very perceptible in the tube, become scarcely sensible when they are thus diffused over a larger extent of surface.

M. Passemont accordingly constructed marine barometers upon this principle; and Mr Nairne, an ingenious artist in London, made one of a similar kind, for Captain Phipps, in his voyage to the north pole. Mr Nairne also suspended his instrument on gimbals, by means of which the effects of the ship's motions were almost entirely counteracted. M. Zeiher has suggested another marine barometer, depending in principle on the variable elasticity of the air. He has proposed a hollow cylinder completely freed from air, with two moveable ends; in the inside of the cylinder, and between the ends, is placed a spring which keeps them separate, and resists the pressure of the air, so that

the degree of its compression affords a measure of that pressure. When the pressure of the air is increased, the two ends of the cylinder approach each other; and when it is diminished, they recede. Consequently the distance between them will indicate the atmospherical pressure in some inverse ratio. See *Mem. Acad. Petrop.* 1758 and 1759.

We shall conclude the account of marine barometers, with a description of one of the most improved kind as now constructed by Mr Troughton. The tube consists of two parts, joined together about five inches below the top: the bore in the upper part being about $\frac{1}{10}$ of an inch, and in the lower part only $\frac{2}{100}$. By this construction, partly from the difference of the bores, and partly from the greater friction in the lower end, the motion of the mercury is so much retarded, that any impulse given by the ship, having a tendency to raise it, will scarcely have produced a sensible effect, before an opposite impulse will be given, having a tendency to depress it.

To counteract more effectually the effects of the ship's motions, the instrument is suspended on gimbals, a representation of which is given at Plate LIV. Fig. 7. The whole is attached to the side of the cabin by two tubes of brass, which slide one within the other, and render the instrument capable of being suspended at different distances from the place of support, that the bottom of it may not strike the side of the cabin, during any heavy rolling of the vessel. See Fig. 8. The inner tube carries the gimbals. The external frame of the barometer is a cylindrical tube of wood, on which slides a brass socket; and in this is inserted the innermost pair of pivots of the gimbals or universal joint, which furnishes the instrument with a moveable point of suspension. The top is terminated with a knob of brass, of a weight nearly equal to that of the mercury, &c. at the lower end. With respect to the position of the point of suspension, no general rule can be given, applicable to every case; though it is a circumstance on which the oscillations of the mercury greatly depend. It is obvious, however, that though this point were accurately determined for one particular height of the mercury, it would not correspond to every other. By the ingenious contrivance of Mr Troughton of placing a knob at the top, as a counterpoise to the weight of the mercury, the centre of gravity of the whole will be about the middle; and if the instrument were of the same specific gravity throughout, the point of suspension that would produce the smallest oscillations in the mercury would be about $\frac{1}{2}$ of the length of the instrument from the top, considering the lower part as a fixed point. But as this is not strictly the case, the point of suspension is best ascertained by experiment. The graduation is on two scales of ivory, about four inches long, for the reception of which, two opposite quarters of the cylindrical frame are *crossed out* through that length, their planes pointing towards the centre of the tube. The index is a very light one, and slides upon the glass tube without touching any other part. At the bottom is the usual screw, which pressing up the leather bag, prevents the mercury from moving when the instrument is carried from one place to another. Fig. 9, and 10, represent sections of this barometer on a larger scale.

After it was observed that the different heights of the mercury served, in some degree, to indicate the state of the weather, many attempts were made to enlarge the extent of the barometrical scale, in order to measure the smallest variations in the weight of the atmo-

sphere. These attempts soon gave rise to a considerable variety of barometers, differing in form from the common barometer, and whose scales, though less accurate, were so much increased in extent, as to point out the most minute changes in the pressure of the air.

Descartes was the first who thought of enlarging the barometrical scale, and for this purpose he invented a barometer which still retains his name. It consisted of a tube of about four feet and a half long, swelled out towards the middle, as represented by CD, Plate LIII. Fig. 5.; AC was filled with water, the point C being about 31 inches above the surface of the mercury in the cistern B. The diameter of the tube AC may be to that of the part CD in any ratio. By this construction, the range of the scale would be nearly as great as if the whole fluid were water, or about 40 inches, if we neglect the weight of the water, which is inconsiderable, compared with that of the mercury. Huygens constructed a barometer of this kind; but, owing to the escape of the air from the water, or to the vapour produced in the vacuum at the top of the tube, the variations were not nearly so sensible as he expected.

He therefore thought of altering the relative position of the mercury and water, in the following manner: ABC, Plate LIII. Fig. 6. is a bent tube, hermetically sealed at C, and open at A. At DE and FG the tube is swelled out into two equal cylindrical vessels, which are about 29 inches asunder. The diameter of the bore of the tube is about 1 line; that of the cylinders 15 lines, and their depth 10. The limb BC is then filled with mercury, and the barometer being placed in a proper position, as much mercury is retained as occupies EBF. Oil of tartar, (a solution of tartarate of potass,) or any other liquor which does not freeze readily, or act upon the mercury, is poured into AE, till it rises to a suitable height above the surface of the mercury at E.

Since the two cylinders are equal, and since their diameters are to the diameter of the tube in any ratio whatsoever, it is evident, that, by this construction, the smallest difference in the atmospherical pressure may be estimated. The scale, however, owing to the nature of hydrostatical pressure, is not capable of being extended beyond certain limits. The liquor will only rise above D, till its weight, together with that of the air, becomes a counterpoise to the mercury in the other limb. Its evaporation is, in some measure, prevented by a thin film of oil on its surface.

This barometer has several defects. The column of mercury is supported above its level at the lower surface, not only by the weight of the air, but also by that of the liquor above it, which increases with the height: when the weight of the air diminishes, the pressure of the liquor increases, and conversely; for the motion of the mercury causing the liquor to increase or diminish in altitude, the apparent effect of the air will be increased or diminished in like manner; the pressure of fluids being in the compound ratio of their bases and altitudes. The friction, varying with the height of the liquor, must be another source of inaccuracy. The liquor itself must also be considerably affected in bulk by heat and cold; and to these inconveniences it may be added, that, notwithstanding the film of oil on its surface, it will gradually evaporate, and render the scale erroneous.

The barometer of Hooke may be considered as an improvement on that of Huygens. This barometer, represented Plate LIII. Fig. 7, is composed of two tubes ABC. The parts AD and EF are equally wide, and the

bore of CE is made as much narrower as it is proposed to enlarge the scale. IBG is filled with mercury, the part AI forming a vacuum. HG is occupied by some fluid lighter than mercury, as a solution of tartrate of potass, and CH by some fluid still lighter, as petroleum, which has little tendency to mix with the other. The cistern C is of the same diameter with AD.

From this construction we may readily perceive the following advantages: The height of the two liquors above the mercury is always the same, whatever be the weight of the air; and the straight tube CE being always filled by the liquors, the friction to which it gives rise must be constantly the same.

The range of the scale, which will be determined by the motions of the line of separation H of the two liquors, will have the same extent as that of the barometer of Descartes and Huygens. Though this barometer is among the best of those with an enlarged scale, it is not free from imperfections: the weight or pressure of the fluids on the surface of the mercury will differ on account of their difference of specific gravity; and they will gradually mix together, so that the line of separation will at last become incapable of being distinguished.

M. de la Hire, in the memoirs of the Academy of Sciences for 1708, speaks of the above method employed by Hooke for correcting the defects of the double barometer; and he says that he mentioned it to Huygens in 1690. M. Amontons also affirms, in a work which he printed in 1695, that the same method had occurred to him eight or ten years before; and that he disclosed it to M. Hubin, who had executed a barometer of the same kind, without having previously communicated with any person on the subject. When Hubin went afterwards to England, Hooke proposed the same thing to him; and indeed the honour of the invention is due to this philosopher, if we adjudge it by priority of claim, for it appears that he had suggested the double barometer which bears his name, in 1668. *Phil. Trans.* No. 185.

We are indebted also to Hooke for the wheel-barometer, which he invented the same year. This form of the barometer, (See Plate LIV. Fig. 11.) on account of its exhibiting the rise and fall of the mercury in a very conspicuous manner, is become extremely common. The tube is generally concealed in the frame; but, for the sake of representing the whole in one figure, we have made it to appear in front; it is about 40 inches long, but six inches of the lower end is bent upwards, so as to become parallel to the rest of the tube.

As an inch of rise of the mercury in the longer leg will cause an inch of descent in the shorter, the bores being equal, the two surfaces will thus be 2 inches apart; and this alteration cannot be effected by a less pressure of the air than that which causes 2 inches of rise in the Torricellian tube. Hence the range of the scale is only half that of the common barometer. But this defect is compensated by converting the perpendicular motion of the mercury into a rotatory one, and exhibiting it on a circular dial plate. For this purpose, a piece of ivory of a bell form is made to float on the surface of the mercury in the shorter leg, having a silk thread fastened to its upper end, which, passing over a pulley, is stretched by a weight that is nearly a counterpoise. By this means the motion of the mercury is communicated to an index, which turns round a graduated circle, and thus the vertical range is enlarged at pleasure. The motion of the index in the wheel barometer has been

rendered more sensible, by Mr Russell of Falkirk, by the addition of a little wheelwork.

Under the same figure we may refer to the syphon barometer; for the form of the tube, and the motion of the mercury, are the same in both. This, at least in theory, is one of the most elegant modifications of the Torricellian tube. It consists of the tube applied to a frame of wood, with the addition of a sliding bar of brass, nearly of the same length. At the lower end of the bar is an index, which, in observing the mercury, is to be set opposite its surface in the shorter leg, the upper end of the bar is divided into a scale of inches, whose zero is the index below. The scale is furnished with a sliding hand for pointing to the surface of the mercury in the longer tube, and also with a vernier for distinguishing the smaller divisions. By this simple contrivance, the sum of the motions of the mercury in both legs is correctly exhibited, and measured at top.

The *inclined or diagonal barometer* (Plate LIII. Fig. 8.) is another form of this instrument, for augmenting the scale. It differs from the common barometer in having the upper part of the tube, where the scale is applied, bent at B, so that the range is on AB instead of *a* B. By this arrangement, when the mercury stands at *d* in the Torricellian tube, it will stand at D in this instrument, D *d* being parallel to the horizon. Hence the scale, compared with that of the common barometer, will be enlarged in the ratio of AB to *a* B; a ratio which admits of unlimited increase, since AB may be made indefinitely great with respect to *a* B.

Of all the methods which have been proposed for increasing the range of the barometrical scale, this seems to be the most susceptible of accuracy. The only objections to which it is liable, are, the friction arising from the increased column of mercury against the sides of the tube, and the possibility of the mercury separating into detached portions during its descent in the inclined part. The invention of the inclined barometer is generally ascribed to sir Samuel Moreland; but this is doubtful. Derham, who has described it in the *Phil. Trans.* for 1698, No. 236, only mentions that it had been communicated to him by a friend. The invention itself is so obvious in principle, that it scarcely merits enquiry to whom it is due.

The *rectangular barometer* (Plate LIII. Fig. 9.) consists of a tube ABC bent at right angles, and swelled out at AD, which includes the vertical range of the mercury into a cylindrical cistern. The scale is reckoned on the horizontal part of the tube CB, and may be enlarged to an unlimited extent, by making the bore of the tube indefinitely small, in comparison of the cistern AD. The mercury is prevented from flowing out at C, by the pressure of the air acting upon its surface at E. When the weight of the air is increased, so as to produce an ascent of one inch of the mercury in the Torricellian tube, it will also produce an ascent of one inch in AD; but in order to do this, the mercury must be supplied from CB, and the space through which it moves from E towards B, will be to one inch, as the square of the diameter of AD to the square of the diameter of the bore of CB.

Another contrivance for enlarging the scale of the barometer, is represented by Plate LIII. Fig. 10. ABD is a bent tube of the common diameter, terminated at the upper extremity by the bulb A, in order that the ascents and descents of the mercury may be chiefly in the leg BD. EG is an index moveable about F as a centre;

DC is a float of ivory or glass, attached by a slender wire to the extremity E of EG, and which, by its ascent and descent on the surface of the mercury, communicates motion to the index. By this means the scale is enlarged in the ratio of FG to EF; but the friction is considerable, so that little reliance can be placed on the degrees pointed out by the index. It may be useful, however, merely to point out changes in the atmospheric pressure, where the real amount of these is of little importance.

We shall conclude the account of the methods that have been proposed for enlarging the extent of the barometrical scale, by a description of a barometer invented for that purpose by Mr Rowning.

In Plate LIII. Fig. 11. ABCD is a cylindrical vessel filled with a fluid to the height W, in which is immersed the barometer SP, consisting of the following parts: The principal one is the glass tube TP, (represented separately by *t p.*) whose upper end T is hermetically sealed; this end does not appear to the eye, being received into the lower end of a tin pipe GH, which in its other end G receives a cylindrical rod or tube ST, and thus fixes it to the tube TP. This rod ST may be taken off, in order to substitute for it a longer or a lesser, as occasion may require. S is a star at the top of the rod ST, and serves as an index by pointing to the graduated scale LA, which is fixed to the cover of the vessel ABCD. MN is a large cylindrical tube made of tin, (represented separately by *m n.*) which receives into its cavity the smaller part of the tube TP, and is well cemented to it at both ends, that none of the fluid may get in. The tube TP, with this apparatus, being filled with mercury, and plunged into the bason MP, which hangs by two or more wires upon the lower end of the tube MN, must be so poised as to float in the liquor contained in the vessel ABCD; and then the whole machine rises when the atmosphere becomes lighter, and *vice versa*. Let it now be supposed that the fluid made use of is water; that the given variation in the weight of the atmosphere is such, that, by pressing on the surface of the water at W, the surface of the mercury at X may be raised an inch higher (reckoning from its surface at P) than before; and that the breadth of the cavity of the tube at X and of the bason at P, are such, that, by this ascent of the mercury, there may be a cubic inch of it in the cavity X more than before, and consequently in the bason a cubic inch less. Now, upon this supposition, there will be a cubic inch of water in the bason more than there was before, because the water will occupy the space which the mercury has left. The whole machine will therefore be rendered heavier by the weight of a cubic inch of water; and, by the laws of hydrostatics will sink till a cubic inch of that part of the rod WS, which was above the surface of the water at W, comes under it. Here, if we suppose this rod so small that a cubic inch of it shall be 14 inches in length, the whole machine will sink 14 inches lower in the fluid than before; and consequently the surface of the mercury in the bason will be pressed, more than it was before, by a column of water 14 inches high. But the pressure of 14 inches of water is equal to one of mercury; and this additional pressure will make the mercury ascend at X, as much as the supposed variation in the weight of the air did at first. This ascent will make room for a second cubic inch of water to enter the bason; the machine will therefore be again rendered so much heavier,

and will subside 14 inches farther, and so on *in infinitum*. If less than 14 inches of the rod be sufficient to make a cubic inch, the scale of variation will be finite, and may be made in any proportion to the common one.

Mr Rowning never actually constructed a barometer according to the above principles, nor, so far as we know, has it been executed by any other person. It might, no doubt, point out very minute changes on the weight of the atmosphere; but the difficulty of adapting a scale to it, would render it of little practical utility.

It is extremely desirable, for meteorological purposes, to have a regular and successive series of the changes which take place in the pressure of the atmosphere during any given period; but as this would require constant attendance on the part of the observer, mechanical contrivances have been adopted for registering the indications of the barometer, and retaining them in a connected form: When the instrument is fitted up in this manner, it is called a *self-registering barometer*.

The most simple kinds of self-registering barometers are such as indicate the greatest rise and fall of the mercury, or its extreme range, during any stated period; and when this only is required, the object is easily accomplished. Of this description is the self-registering barometer, invented by Alexander Keith, Esq. F. R. S. Edinburgh. It consists of a bent tube, such as ABD, Plate LIII. Fig. 12, hermetically sealed at A. The mercury in the shorter leg supports a float, to which is affixed a slender wire terminating in a bend or knee. This knee embraces a very small wire stretched along the scale, and pushes upwards or downwards two bits of glazed silk which slide along the wire very easily, yet so as to retain the position to which they are moved by the ascent and descent of the mercury. The instrument is prepared for experiment by bringing the two bits of silk in contact with the bent knee of the float-wire; the points to which they may afterwards be removed, indicate the extreme range of the mercury during the interval of any two observations.

When not only the greatest and least altitude of the mercury is sought for any given time, but also its precise height at every intermediate moment, more complicated contrivances must be employed: the instrument must then consist of a barometer connected with a time-piece, and a crayon or pencil affixed to a float obeying the motions of the mercury. The greater number of self-registering barometers of this nature are so constructed, that the crayon is made to describe a continuous line on a vertical cylinder, turning on its axis by means of clock-work, and making a certain number of revolutions in some stated time. The cylinders are divided longitudinally by parallel lines into equal spaces, corresponding to some particular portion of time; and thus the line described by the crayon in that time, indicates the successive heights of the mercury during its continuance.

M. d'Ons-en-Bray was the first who applied the pendulum to meteorological instruments; but, in every contrivance which has been adopted, the great friction arising from the traces of the crayon prevents, in a considerable degree, the free motion of the mercury, so that the indications of the register are little to be relied on. The description of another instrument of a more improved construction, invented by M. Changeux, will be seen in the *Nouvelles de la République des Lettres et*

des Arts, par M. Blancherie 1779, p. 134, 167, 170, 187; and 1781, p. 30.

The principle proposed by Dr Brewster, in the article *ATMOSPHERICAL CLOCK*, for measuring the mean temperature of the atmosphere, during any given interval, may also be employed in the construction of a barometrical clock; by which the average height of the barometer, during any given time, will be indicated on the dial plate. The same construction is applicable to the hygrometer.

We shall conclude this article with a description of several instruments which have been suggested for measuring the pressure of the atmosphere, which, though founded on just principles, are rather curious than useful.

The *conical* or *pendant barometer*, invented by M. Amontons in 1695, consists of a truncated conical tube, hermetically sealed at one end, and suspended in a vertical position. It has no cistern; the conical figure of the tube, and the smallness of the bore, rendering that unnecessary. The length may be varied at pleasure, and will depend on the conical form of the bore; so that the slower the degree of contraction, the more extended will be the scale. Thus suppose 28 inches of mercury in the lower part of the tube occupied 31 inches, 80 inches higher the range would be 80—28, or 52 inches.

This instrument may be employed as a marine barometer; but the friction of the mercury is so great, owing to the bore of the tube being necessarily very small, that it is seldom used.

The *statical barometer* of Otto de Guericke, Boyle, and others, consisted of a large hollow sphere fixed at one end of the arm of a delicate balance, counterpoised by a weight of brass at the opposite. These two bodies being of the same weight, but of different volumes, if the fluid or medium in which they are suspended becomes more or less dense, an apparent change of weight will take place, and the equilibrium will be subverted. If the air becomes heavier, the hollow ball will appear to become lighter, as it will lose more of its weight than the counterpoise, which is more dense; on the other hand, if the air becomes lighter, a contrary effect will happen. This barometer is obviously founded on the hydrostatical principle, that a body suspended in a fluid loses as much of its weight as is equal to the weight of the fluid displaced. *Phil. Trans.* 1666. No. 14.

Fahrenheit proposed a barometer, founded, in principle, on the well-known fact, that the boiling point of liquids varies with the pressure on their surface. If a thermometer be taken with a large bulb, and a small bore, and the boiling points of water be marked upon it, corresponding to the various heights of the mercury in the Torricellian tube at the time of observation, the divisions on the thermometer will indicate the pressure of the air, when the instrument is afterwards plunged into boiling water. The range of the scale, however, would be very limited; as a change of atmospheric pressure, causing a descent of one inch of the mercury in the barometer, depresses the boiling point of water only $1\frac{1}{2}$ degrees; the instrument would also be troublesome in application.

In the *Philosophical Transactions*, a barometer of the following construction is described by Mr Caswell: ABCD, Plate LIII. Fig. 13. is a vessel filled with water, in which is immersed the barometer *msoyzerx*, consisting of a body *msoerx*, and two tubes *cx* and *oyze*.

The body and the lower tube are hollow cylinders, and communicate with each other. The lower extremity of the tube *yz* has a weight affixed to it, to make the instrument sink, so that the top of the body may just swim even with the surface of the water, by the addition of necessary weights on the top. When the instrument is forced with its mouth downwards, the water ascends up into the tube to the height *ut*; and the small concave cylinder *cx* at the top gives buoyancy to the whole, and prevents the instrument from sinking below the proper depth; *md* is a wire; and *mS* and *cd* are two threads stretched obliquely to the surface of the water, in order to increase the range of the scale. An alteration of the gravity of the air causes the instrument to subside more or less; and a small bubble is formed where the surface of the water cuts the threads, which ascends and descends along them, as the mercury ascends and descends in the common barometer. This instrument is much commended by its inventor for its extreme delicacy; but the difficulty of applying an accurate scale to it, renders it of little value.

On the whole, it may be remarked, that the principle of the Torricellian experiment affords the best method of constructing the barometer with accuracy; particularly as, by means of a vernier scale, the height of the mercury may be readily determined to the thousandth part of an inch; a degree of correctness sufficient for every scientific and practical purpose, and which cannot be obtained with certainty by constructions of a more complicated nature.

The references to works on the subject of barometers will be given with more propriety under the articles *HEIGHTS* and *METEOROLOGY*. (A)

BARON, a distinguished person, originally holding a barony; and now either holding a barony, or capable, by letters patent, of sitting and voting in the upper house of parliament.

Etymologists are not agreed with respect to the derivation and primary meaning of this term. The most probable account of it is, that the word baron is of German or perhaps of Celtic extraction, and that, in the language of those who first employed it, it was synonymous with *man* in general. It has this meaning in the Salic law, and in the laws of the Lombards; Philomenes renders it by *avng*, and in the English law, the phrase "baron and feme" is equivalent to that of man and wife. Retaining its general sense, it appears next to have been used, either in *benam*, or in *malam partem*; in the former, as when it was employed to denote a man of respectability, (*avng, vir*.) a stout or valiant man, and in the latter, as when *barone* is used by the Italians, to signify a beggar. From denoting a stout or valiant man, it was employed *καὶ ἐξοχη* as a name for a distinguished military leader; and particularly for one of those captains, who, having fought and conquered under some great commander, were afterwards rewarded by him with a part of the lands which he had acquired. This part became the property of the new possessor, and descended to his heirs, on condition of military service; understanding by these words assistance in the formation and direction, as well as in the execution of military schemes. Such was the import of the term baron, when the feudal system was established, and while its earliest institutions continued in their vigour; but changes having taken place in the state of society, and the feudal institutes having been modified or abolished,

it gradually acquired the meaning which we have attempted to express in the definition at the beginning of this article. As explanatory of that definition, it may here be added, that, in reference to those who are capable of sitting and voting in the upper house of parliament, the word baron is used with a certain variety of signification. Thus, in a general sense, all noblemen are barons; as when we say, that the Duke of Norfolk is, with the exception of the blood royal, the first baron of England, or that the Duke of Hamilton is, with the same exception, the first baron of Scotland; but, in a sense more limited and appropriate, he only is a baron who has rank and place immediately after a viscount.

In the history of most European countries, the barons are represented, either as feudal lords, in possession of a certain authority over their vassals, and of certain benefits resulting from that authority; or, as the chief officers and functionaries of the crown, summoned by the monarch, as occasion required, to assist him with their advice, and attend him in his expeditions; and contributing to the dignity, as well as the efficacy, of his government, in a way similar to that in which their own vassals were bound to support them in their own individual capacity. They are to be viewed either as masters or as servants; as masters, with respect to those who acknowledged their feudal jurisdiction; and as servants, with respect to the king, whose ministers and dependants they were. See FEUDAL SYSTEM.

When we consider them as feudal superiors, we perceive them exercising many of the rights, and enjoying many of the privileges, which are now exclusively attached to royalty. Thus we find them declaring war and making peace; issuing from their castles at the head of their retainers, harassing each other with perpetual inroads and devastation, and often transmitting their resentments under the name of *faida*, or deadly feuds, to succeeding generations.* The history of Europe, during a period extending from the seventh to the eleventh century, is little more than a record of wars and excursions, undertaken without a regular plan, and followed by no other consequences than the declension of one great family and the rise of another. In particular circumstances, too, we find the barons laying aside their animosities, and mutually engaging to abstain from all acts of hostility. And in these agreements, they neither consulted the will of the monarch, nor were, in any way, solicitous about his approbation or displeasure. A remarkable instance of a truce between the Earl of Gloucester and the Earl Marshall, and into which Morgan, the son of Hoek, a Welsh prince, was allowed to enter or not, as he should think fit, is given by Dr Stuart, in the Appendix to his View of Society in Europe, No. 4, to which, as corroborative of the preceding statements, we beg leave to refer our readers.

A second privilege of the feudal lords was, that of trying causes and distributing justice among their vassals. This privilege seems to have belonged to many of them in its fullest extent. There is a distinction recognized by those who have given us any account of the feudal times, between what was denominated the high and the low justice; *justice haut et bas, alte et*

basse; and to this distinction it is necessary that we attend, in order to form an accurate idea of the judicial and executive powers which were vested in the feudal lords. The high justice comprehended offences of every description, whether criminal or civil; and especially those which were punishable "*ferro, fossa, et furca*," (Du Cange, *voc. fossa*: Tacit. *De Mor. German. c. 12.*) while the low justice was confined entirely to civil offences, and even in regard to these, was limited to petty transgressions. While all the barons claimed the right of administering the low justice, some of more extensive territory and of greater power, both claimed and exercised the right of administering the high. They determined causes in which the life or death of the offending party was concerned. As they commanded their vassals in the field, so they settled disputes and ordained punishments in the great hall of their castles. It was here that the baron's court was held: And as the king was often unable to interfere with his nobles in the exercise of their authority, and had even in some instances, as in those of regalities and counties palatine, engaged himself never to do so, the decision of that court was final. Appeals were altogether unknown at the time when the power of the feudal aristocracy was at its height. But it would have been in vain to determine a cause against any individual without the means of carrying the sentence into effect. It was therefore necessary, or at least expedient, that the baron should call to his assistance a number of his other vassals, both in ascertaining the extent and nature of the evil, and in awarding the punishment. This was the more requisite when fiefs had become perpetual, and the territorial superior found himself obliged to a more circumspect and equitable distribution of justice among his retainers. Hence arose the *fares curia*, the assessors or jurymen, whom all modern history acknowledges to have been present in the baronial courts, not as compurgators or witnesses, but as actual judges of right and wrong. Hence too the existence of juries at present; and hence that glorious maxim of British law, and proudest privilege of freedom, "that no man can be condemned unless after a trial by his peers." Before we conclude this part of the article we may observe, that in feudal times, the right of pardon uniformly accompanied those of judging and punishment.

A third privilege of the great barons, now attached exclusively to royalty, was that of coining money. There can be no question that they enjoyed this privilege, though it has been less attended to by writers on the feudal system, than those which we have mentioned. Du Cange, in his article *Moneta*, introduces several documents which establish its existence, and to these he adds an enumeration and description of the baronial coins. The privilege alluded to was, no doubt, in some degree, the result of necessity. A mark, or stamp, was wanting to indicate the purity and value of the metals in use: the king was often at a distance, little heard of, and not much regarded; but the territorial superior was always at hand, and his authority within the limits of his jurisdiction was, in many respects, exclusive and final. His mark, or stamp, therefore, became the index to his vassals, that the money which circulated among them was of the proper fineness and

* *Le Duc Sarragresile, ayant été tué par quelqu'un de ses ennemis les Grands du Royaume citerent ses enfans qui negligeoient de venger sa mort, et les privoient de sa succession.* Saint Foix. *Essais Hist.* tom. ii. p. 88. In this instance, the children were punished for neglecting to exercise the right of private vengeance.

weight. The right of coinage, thus assumed and exercised, was afterwards recognised by many of the sovereigns and parliaments of Europe. It belonged to the ecclesiastical as well as to the lay barons. In an agreement between Philip the Fair and one of his bishops, (A. D. 1307,) the words of which are quoted by Du Cange in the article already referred to, it is established that the money of the bishop shall have a free circulation through the whole of his diocese, and that beyond the pale of his ecclesiastical authority it shall have the same currency, "*Quam Moneta aliorum baronum nostri regni habebant extra terras suas.*" "*Quod monetas ergo,*" infers the writer "*iusdem privilegii quibus laici barones, gaudebant episcopi.*"
